Printed in Great Britain.
W. & R. CHAMBERS, LTD., LONDON and EDINBURGH.

LIST OF MAPS IN VOLUME VIII.

POLAND AND LITHUANIA	<i>facing page</i>	257
SOUTH POLAR REGIONS	" "	264
NORTH POLAR REGIONS.	" "	265
QUEENSLAND	" "	504
ROMAN EMPIRE	" "	761
RUMANIA (RÔMANIA)	" "	825
RUSSIA	" "	841

Among the more important articles in this Volume are the following:

PENSIONS.....	G. S. W. EPPS.	PSALMS.....	Professor T. K. CHRYNE.
PENTATEUCH.....	Dr STANLEY A. COOK.	PSYCHOLOGY.....	Dr WILLIAM G. SMITH.
PEPYS.....	H. B. WHEATLEY.	PUERPERAL FEVER; PU-	
PERIODICALS.....	LORD RIDDLE.	ERPERAL INSANITY.....	Professor R. W. JOHNSTONE.
PESSIMISM.....	Professor W. CALDWELL.	POTREFACTION; REN-	
PETERBOROUGH.....	H. D. TRAILL.	NET.....	Professor A. HARDEN.
PETRARCH.....	SIGNORA CANTAGALLI.	PYRAMID.....	STANLEY LANE POOLE.
PETROGRAPHY.....	Professor JAMES GEIKIE.	Q; R; S.....	Dr HENRY BRADLEY.
PETROLEUM.....	V. C. ILLING.	QUANTUM THEORY.....	Professor WILLIAM PLEDGE.
PHILOLOGY.....	Dr PETER GILES.	QUATERNIONS.....	Dr CARILL G. KNOTT.
PHILOSOPHY.....	Professor A. S. PRINGLE-PATTISON.	QUEENSLAND.....	A. W. JOSE.
PHENICIA.....	CAROL RAWLINSON; Dr S. A. COOK.	QUEVEDO.....	JOHN ORMSBY.
PHONETICS.....	Professor DANIEL JONES.	QUININE.....	Professor RALPH STOCKMAN.
PHONOGRAPH.....	W. H. MEADOWCRAFT.	RABBI; RASHI.....	HARPER LOIWE.
PHOSPHORESCENCE (Or-		RABELAIS.....	Sir WALTER BESANT.
ganic).....	Professor J. ARTHUR THOMSON.	RADIUM.....	Sir OLIVER LODGE.
PHOTOGRAPHY.....	C. W. GAMBLE; W. B. HISLOP.	RAILWAYS.....	E. R. M'DERMOTT.
PHYSICAL CHEMISTRY..	Dr E. B. JUDLAM.	RAIN.....	Dr BUCHAN; R. C. MORRAN;
PHYSIOLOGY.....	Professor W. D. HALLIBURTON.		R. CORLESS.
PHYSIOLOGY (Veget-		RAINBOW.....	W. T. OMOND.
able).....	Dr R. J. D. GRAHAM.	RĀMĀYANA.....	Professor A. BERRIEDALE KEITH.
PIGMENTS OF ANIMALS.	Professor J. ARTHUR THOMSON.	RAPHAEL.....	Sir JOSEPH CROWE.
PISCICULTURE.....	WILSON H. ARMISTEAD.	READER, CHARLES.....	F. HINDEN GROOME.
PITT.....	W. E. H. LECKY.	RECORDS.....	Professor R. K. HANNAV.
PIAZZO.....	Sir CLYMENTS R. MARKHAM, K.C.B.	RED SEA.....	Sir JOHN MURRAY.
PLANETS.....	Sir FRANK DYSON, Astronomer-	REFLECTION; REFRAC-	
	Royal.	TION.....	Dr ALFRED DANIELL.
PLANKTON.....	Dr R. N. RUDMORE-BROWN.	REFORMATION.....	Professor P. HUMPHREY BROWN.
PLANTS (Movements of)	Dr R. J. D. GRAHAM.	REFORMATORIES.....	Miss LILLIAN M. HUSSELL; Dr ARTHUR
PLATO.....	D. G. RICHIE.		H. NORRIS.
PLEISTOCENE.....	Professor JAMES GEIKIE.	REFRIGERATION.....	LUDWIG M'QUEEN DOUGLAS.
PLINY.....	Dr J. P. STERILE.	REGISTRATION.....	Sheriff J. M. IRVINE, K.C., LL.D.
PLOUGH; POTATO.....	JAMES MACDONALD; Professor J.	REINCARNATION.....	NORRIS W. THOMAS.
	A. S. WATSON.	RELATIVITY.....	Professor WILLIAM PLEDGE.
PLUTARCH.....	Rev. H. A. HOLDEN, LL.D.	RELIGION.....	Dr STANLEY A. COOK.
POACHING.....	LORD SANIES.	REMBRANDT.....	P. G. HAMILTON.
POETRY.....	Sir EDMUND GOSSE.	REPORTING.....	H. ROBBINS.
POISON.....	Professor RALPH STOCKMAN; NOR-	REPRODUCTION.....	Professor J. ARTHUR THOMSON.
	MAN MACDONALD, Advocate.	RESPIRATION.....	Professor HALLIBURTON.
POLAR EXPLORATION...	Sir JOHN S. KILPATRICK; Dr R. N.	REVELATION; ROMANS.	Rev. Professor HERBERT T.
	RUDMORE-BROWN.		ANDREWS, D.D.
POLE (Cardinal).....	T. G. LAW.	RHIZOME; ROOT.....	GEORGE WEST.
POLICE.....	A. L. DIXON.	RICHARDSON.....	AUSTIN DOBSON.
POLITICAL ECONOMY...	T. KIRKPUR; Dr MARY T. RANKIN.	RIFLES; ROCKET.....	Colonel Sir HILARY BARLOW, Bart.
POLYSENIA.....	W. J. PERRY.	RIVER.....	HUGH R. MILL; Sheriff IRVINE;
POMPEII.....	Dr THOMAS ASHBY.		D. and C. SILVERSON.
POPE.....	Rev. W. HUNT; Cardinal GASQUET.	ROADS.....	Professor Sir THOMAS HUDSON
POPE, ALEXANDER.....	H. D. TRAILL.		BEARE.
POSITIVISM.....	JAMES OLIPHANT.	RODNEY.....	Professor Sir J. K. LAUGHTON.
POST-OFFICE.....	A. J. TURNER.	ROGERS.....	F. HINDEN GROOME.
PRAGMATISM.....	HENRY BARKER.	ROMAN ARCHITECTURE;	
PRĀKRIT.....	Professor A. BERRIEDALE KEITH.	ROMANESQUE ARCHI-	
PRECEDENCE.....	Sir JAMES BALFOUR PAUL, Lyon King.	TECTURE.....	Dr THOMAS ASHBY.
PRIE-RAPHAELITISM.....	W. HOLMAN HUNT.	ROMANCES.....	JOHN ORMSBY.
PRINTING.....	CHARLES T. JACOBI.	ROME (History).....	Dr J. P. SIEBEL; Dr ASHBY.
PRIOR; PRIORY.....	AUSTIN DOBSON.	ROME (Topography).....	Dr THOMAS ASHBY.
PRISONS.....	Sir EVELYN HUGGLES-BRICE; DAVID	RÖNTGEN RAYS.....	Professor C. G. BARKLA.
	CHROMBIE.	RO-SETTL.....	W. M. ROSETTL.
PRIVY COUNCIL.....	Sir A. WOOD RENTON.	ROUSSEAU.....	Rev. H. G. GRAHAM.
PROBABILITIES.....	R. E. ANDERSON.	ROWING.....	W. R. WOODBRIDGE; CHARLES M.
PROTECTION.....	LORD BIRKENHEAD.		PITMAN.
PROTOPLASM.....	Professor J. ARTHUR THOMSON.	RUBENS.....	J. M. GRAY.
PROVENÇAL.....	A. P. GOUVY.	RUGBY.....	CHARLES NOWELL.

A great many of the articles named above are new; others written for earlier issues of this Encyclopedia have been so thoroughly revised by their authors as to be virtually new. In addition to these many other revisers have taken part, including Professor J. A. S. WATSON (Agriculture), Professor DAVID HEPBURN (Anatomy), Dr DRINK-WATER (Chemistry), Dr R. CAMPBELL (Geology), Mr G. E. SHEPHERD (India), Dr THOMAS ASHBY (Italy), Mr W. A. FLEMING, Advocate, and Mr NORMAN MACDONALD, Advocate (Law), Dr J. D. COMRIE (Medicine), Admiral Sir REGINALD TUPPER (Navy), Dr ALFRED DANIELL (Physics), the editor and staff of the *Railway Gazette* (art. RAILWAYS), Professor A. BERRIEDALE KEITH (Sanskrit), Dr S. A. COOK and Mr HERBERT LOEWK (Semitic Subjects), Dr F. E. BEIDARD and Professor J. ARTHUR THOMSON (Zoology). Thanks are due for the reading of proofs to Lord POLWARTH (art. PRISONS), Dr C. S. MYERS (art. PSYCHOLOGY), and Miss M. A. MURRAY (art. PYRAMID); and to many town-clerks and others for information and corrections.

CHAMBERS'S ENCYCLOPÆDIA

A DICTIONARY OF UNIVERSAL KNOWLEDGE

Penobscot, a river of Maine. The West Branch rises near the Canadian frontier, and flows east and south-east to where it meets the East Branch or Sebasticus River. Afterwards its course is south-south-west to Penobscot Bay, a broad and sheltered inlet of the Atlantic Ocean, 35 miles long

and 20 wide, with numerous islands. It is tidal and navigable for large vessels to Bangor, 60 miles from its mouth. The chief trade is in lumber.

Penrhyn. See CARNARVONSHIRE, BANGOR, BETHESDA, and SLATE.

Penrith, a market-town of Cumberland, in a picturesque and fertile valley, on the outskirts of the Lake District (q.v.), 18 miles SSE. of Carlisle. It has a fine old ruined castle, where Richard III. (then Duke of Gloucester) is said to have resided, and a grammar-school (1395; refounded 1564). In the churchyard are two ancient monuments, the 'Giant's Grave' and the 'Giant's Thumb,' often visited by Sir Walter Scott; and north-east of the town is the wooded Beacon (937 feet). Pop. 8300.

Penryn (Corn., 'head of the river'), a town of Cornwall, at the head of a creek of Falmouth harbour, 3 miles NW. of Falmouth, with which till 1918 it returned one member to parliament (till 1885 two). Scarcely a trace remains of Glasney College, founded in 1264 for thirteen Black Augustinian Canons; and none of a palace of the bishops of Exeter. Neighbouring quarries supply the famous Penryn granite—the material of Chatham Docks and other great public works; and the town has besides some flour and timber milling and manufactures of chemicals. Incorporated by James I., it was taken by Fairfax in 1646. Pop. 3000.

Pensacola, a port of entry and the capital of Escambia county, Florida, is 244 miles by rail ENE. of New Orleans, on the west shore of a deep bay opening into the Gulf of Mexico. The entrance is defended by Fort McRee and Fort Pickens, the latter on Santa Rosa Island; and near by is the

principal American naval air-station. Pensacola contains saw and planing mills, and ships large quantities of yellow pine. It was settled by the Spaniards before 1700, occupied by the British from 1763 to 1781, and afterwards during the wars with Napoleon, taken by Andrew Jackson from the British in 1814 and the Spaniards in 1818, and passed with the rest of Florida to the United States in 1819. Pop. (1880) 6845; (1910) 22,982; (1920) 31,035; (1925) 25,305.

Penshurst, a village of Kent, 5½ miles SW. of Tonbridge. Penshurst Place, rich in literary associations, was Sir Philip Sidney's birthplace.

Pensionary is the name formerly given to the syndic or legal adviser in every important town of Holland.—During the republic of the United Netherlands, the first minister of the province of Holland was called *Raadspensionaris*—Englished by State Pensionary, or, more commonly, Grand Pensionary. The Grand Pensionary had no vote in the assembly of the States, and could only bring forward the subjects of discussion. He, however, collected the votes, wrote the decrees, read the letters addressed to the States, conducted negotiations with foreign ambassadors and ministers, and took charge of the revenues of the province, and whatever else pertained to its welfare. The office was abolished in 1795, after the conquest of Holland by the French revolutionists. Olden Barneveldt, De Witt, and Heinsius were its most celebrated holders.

Pensioners. See GENTLEMEN-AT-ARMS.

Pensions may be broadly divided into superannuation allowances and rewards for special services. Great sums are required for superannuation in the various departments of state, including the consular, diplomatic, and colonial services, and in the fighting services. The pensions granted from the Civil List (q.v.) to persons in straitened circumstances who have merited special distinction by their discoveries in science or their attainments in literature or in arts, are altogether on a different footing from those in the civil service, which last are part of the condition of employment, and are thus in the

nature of deferred pay. Of the same nature is the retired pay of officers in Navy, Army, and Air Force, as well as the service pensions of other ranks. The enormous character of the burden of the non-effective services has given occasion for much discussion, and has called forth many suggestions. Thus, in the session of 1888 a motion was carried in the House of Commons, the effect of which is to restrict the system of compulsory retirement on pension of civil servants. The principle has been laid down that officials no longer required in their own departments who are still able and willing to render service for the public money should be provided with employment in other departments, instead of being forced to become useless burdens upon the country. Perpetual pensions must be regarded as somewhat of an abuse of the principle upon which a state rewards good and faithful servants. The matter became the subject of a parliamentary inquiry on the initiation of Mr Bradlaugh in 1887. A select committee was appointed, which, after taking evidence of a curious and interesting kind, recommended that no more pensions or allowances should be granted in perpetuity. This committee also reported in favour of the abolition of all sinecure offices with salaries but no duties, and recommended that all existing perpetual pensions, allowances, and payments, and all hereditary offices, should be determined and abolished. In commutating such pensions it has been laid down as necessary to differentiate cases of grants for actual services by the original grantees, and cases of mere gratuity. Where no service or merely nominal service was rendered either by the present holder or the original grantee it was proposed that the payment should in no case continue beyond the life of the present holder. In former commutations of perpetual pensions a scale of twenty-seven years' purchase was usually adopted. On or about this scale there were, between 1881 and 1887, 330 pensions and allowances of the annual value of £18,957 commuted for a sum total of £527,933. The rate was reported to be too high, and in the session of 1888 a motion was passed for giving effect to the recommendation of the select committee, and for a return in detail of all outstanding hereditary pensions and the circumstances in which they were granted. Pensions such as those of £4000 per annum to the Duke of Marlborough, and of £5000 to Earl Nelson, and to their heirs in perpetuity, are, of course, well understood as in return for 'value received' in special services to the state. In 1925 a pension of £2000 held by a great-great-grandson of the distinguished admiral Lord Rodney was commuted for £42,000, and the only pension of this kind then remaining was that enjoyed by the descendant of Earl Nelson. The objection to the principle of such pensions is that it is a burdening of posterity with payment for services rendered to one generation. The rewards for distinguished services should be defrayed by the generation receiving the benefit of them, and should be conferred upon the persons who actually render them, either in the form of a capital sum down, or of a life pension only.

There are, again, a number of hereditary pensions conferred not for services, but as *solatium* for the loss of the fees of abolished offices. Thus, when the offices of *Custos Brevium* and Clerk of the Juries were abolished in 1837 the holders were compensated with hereditary pensions of £786 each. These were commuted on a basis of twenty-seven years' purchase. One of the numerous perquisites conferred by Charles II. on his illegitimate son, the Duke of Grafton, was that of Officer of the Pipe, or Remembrancer of First Fruits and Tenths of the Clergy in the Court of Exchequer. This office was sold by the duke in 1765, and when the fees were abolished the holder was compensated with a per-

petual pension of £62, 9s. 8d. A still more remarkable case was that of the hereditary office of Master of the Hawks, granted by James II. to the Duke of St Albans and his heirs for ever. The emoluments consisted of £391, 1s. 3d. as salary, £200 for four falcons, £600 for provision of hawks, and £182, 10s. for other provisions—together, £1373, 11s. 3d. This total was subsequently reduced to £965, at which it stood until commuted, in 1891, for £18,335, although there had been neither hawks nor falcons for many generations. A pension of £4000 per annum granted in 1779 to William Penn, the founder of Pennsylvania, and his heirs for ever, was in 1884 commuted for a ten years' annuity of £12,796, considered equivalent to twenty-seven years' purchase. In 1676 Charles II. granted to the Duke of Richmond and his heirs for ever a duty of one shilling per ton on all coals exported from the Tyne for consumption in England. One hundred years later that charge was converted into a perpetual pension of £19,000 (chargeable on the Consolidated Fund), which, again, was afterwards redeemed for £633,333, and invested in lands settled upon the duke and his heirs. The Duke of Hamilton, as Hereditary Keeper of Holyrood, has an hereditary pension of £45, 10s., and the descendants of the Heritable Usher of Scotland enjoy one of £242, 5s. These are a few of the examples of a wholly indefensible system. There are also limited hereditary pensions granted for a certain number of lives, which are not so unjustifiable, as, for instance, the pension of £4000 to the Duke of Wellington and two successors, and the pension of £2000 to Lord Napier of Magdala and one successor. In 1925 there was only one of these limited hereditary pensions in existence, namely, that held by Lord Seaton, and his will terminate on the death of the present beneficiary. This system of reward for military service has not been adopted in recent years, the grant usually taking the form of a lump sum. Thus a grant of £30,000 was made to Earl Kitchener after the relief of Khartum. Earl Roberts received a sum of £100,000 on the conclusion of the South African war, an additional £50,000 being awarded to Earl Kitchener. After the Great War grants of £100,000 were made to Earl Beatty and Earl Haig, smaller sums being given to several other distinguished officers.

A minister of the crown who has held office (not necessarily continuously) for a specified period of service may claim a pension if his income from other sources is insufficient to maintain him adequately. The amount of pension is £2000, £1200, or £800, according to the office held; the number of such pensions is limited by statute to twelve. Similarly a Lord Chancellor of England is granted on retirement from office a pension of £5000, and judges of the Supreme Court are entitled to receive pensions equal to two-thirds of salary after fifteen years' service or on becoming permanently incapacitated from duty; county court judges and certain other officers of the courts are also granted analogous benefits. In the case of an established civil servant a pension calculated at one-eighth of his final salary (or in certain circumstances the average salary of the last three years) for each year's service is granted on retirement at age sixty or over, or earlier if he has broken down in health, after not less than ten years' service; in addition a lump sum equal to one-thirtieth of salary for each year is paid on retirement. If death occurs during service a year's salary is payable to the officer's estate. The foregoing scales apply to male officers and are subject to qualifying conditions and limitations laid down in the Superannuation Act 1900; the benefits of women and of entrants before that act are somewhat different. The whole of the cost of the pensions of civil servants

is met out of public funds. The superannuation rights of elementary school teachers (and certain other classes of teachers) are prescribed in the Teachers' Superannuation Act, 1925; part of the cost is derived from the joint contributions of the teachers and the education authorities, and the balance from the Exchequer. Similarly the police are required to contribute towards the cost of their pensions.

The rules governing the award of pensions to officers and men in the Navy, Army, and Air Force are somewhat complicated and are varied from time to time owing, *inter alia*, to changes in the cost of living; for precise information, therefore, reference should be made to the official regulations applicable to the particular arm of the service. After the Great War the scales and conditions were extensively modified, and, as far as possible, the arrangements applicable to Navy, Army, and Air Force respectively were brought into line. Broadly speaking, pensions granted on retirement from service are based both on the rank of the officer or man and on his period of service. Navy pensions were first instituted in the reign of William and Mary. Those for officers may be classed as follows: good service pensions, Greenwich Hospital pensions, pensions for wounds, and the ordinary pension to which an officer may be entitled on retirement, now known as retired pay. No officer is entitled to a retiring pension until he is forty years of age; should he retire earlier he receives merely the half-pay of his rank, except in the case of junior officers who are invalided, when a further allowance is made. The maximum retired pay of an admiral of the fleet is £1800, admiral £1425, vice-admiral £1195, rear-admiral £1010; in these cases thirty years' sea service as a commissioned officer is requisite; in addition a good service pension of £300 may be held. The maximum retired pay of a captain is £900, commander £600, lieutenant-commander or lieutenant £450, the normal age at retirement being fifty-five, fifty, and forty-five respectively. The good service pensions, so-called, consist of ten of £300 a year for admirals, which may be held after retirement, and of eighteen of £150 a year for captains, those last are conferred on captains on the active list, and are relinquished when their holders are promoted to rear-admiral or retire. Seamen and marines are entitled to a pension after twenty-two and twenty-one years' service respectively (disregarding any period before attainment of age eighteen); the basic rate is 1½d. per day for each year's service, plus additions for 'very good character,' good conduct medal or badges. On attainment of age fifty-five an addition of 5d. a day is made, with a further increase of 4d. when age sixty-five is reached. Petty officers receive the seamen's rates, plus a rank allowance varying with length of service in that capacity. Greenwich Hospital pensions, which may be held in addition to ordinary pensions, date from the reign of William III., when Queen Mary established the hospital for infirm and aged seamen. These pensions range from £150 for flag officers to £30 for warrant officers; they are limited in number, and are divided into numerous classes. There are also pensions for wounds, varying with the rank of the officer or man and with the nature of the injury; and special pensions may be given to men unable to contribute materially to their support. Pensions are also given to the widows of officers in certain circumstances, and compassionate allowances made to their children or other dependents.

In the case of the Army the retired pay of an officer consists of a sum depending on his length of service (£150 after fifteen years, with an addition of £15 for each year in excess), plus an allowance for rank (e.g. £12 for each year

of service as a major); there are, however, over-riding maxima of £300 for a subaltern or captain, £450 for a major, rising to £1400 for a general. Non-commissioned officers and soldiers receive pensions similar to those granted to seamen; in their case too the basic rate is 1½d. a day for each year's service (21 years or over), plus rank allowance, and the increases at age fifty-five and sixty-five apply also. Formerly these age additions were granted only to naval pensioners, but the different branches of the service were brought in line after the Great War. In the Air Force the retired pay of an officer is similar to that of an Army officer of corresponding rank, but is further complicated by regard being had to whether he was employed on general duties (e.g. flying) or in the stores branch. Owing to the need for young flying officers a considerable proportion are granted short service commissions and on retirement receive only a gratuity. For other ranks the rates and conditions are generally similar to those applicable to soldiers, save that the normal period of qualifying service is twenty-four years instead of twenty-one years. Holders of the Victoria Cross and others who have been rewarded for gallant conduct receive additional allowances. The awards to officers and men invalided from the service on account of wounds or other injury depend, *inter alia*, upon the degree of incapacity.

GREAT WAR PENSIONS.—Soon after the outbreak of the Great War it was apparent that the pension schemes for disabled men and for widows during previous wars were unsuited to a war in which the whole nation took up arms. Revised scales were adopted by the Admiralty and the War Office which are set out in Parliamentary Paper Cd 7662 together with the superseded scales; the whole question was, however, referred to a Select Committee of the House of Commons, appointed in November 1914, which recommended further substantial increases. For example, the widow of a private soldier without children who in previous wars would have received a pension of 6s. a week, was granted a pension of 10s. (increasing to 12s. 6d. at age thirty-five and 15s. at age forty-five); and a widow with four children 22s. 6d. (or more if the mother was over thirty-five), in place of 11s. hitherto in force. In the case of men totally disabled, a private received a pension of 25s. (with an additional allowance of 2s. 6d. for each child); if the man was partially disabled he received such proportion of the above sum as would, with the wages he was capable of earning, amount to 25s., but in no case less than 10s. 6d. for the loss of a limb or an eye. Separate scales were laid down for various classes of officers, nurses, and non-commissioned officers, and also for dependants other than widows and children. During the early years of the war the award and payment of pensions to naval ratings was normally vested in the Admiralty, the corresponding functions in regard to soldiers being exercised by the Army Council. But with increase in the number of pensioners and the consequent administrative strain on the fighting departments the work was transferred to a new *ad hoc* department, the Ministry of Pensions, which became responsible from 1917 onwards for all war pensions payable to soldiers and seamen or their dependants; later, when the Air Force was constituted as a separate unit, the functions of the Ministry of Pensions were expanded. In 1917 the pensions warrants were revised in the light of experience in various directions [Cd 8485].

The principal changes were (1) to increase the pensions of disabled men, especially if they had children; (2) to apply the standard scales to men disabled in the highest degree, proportionately

smaller pensions being granted according to the prescribed degree (measured in tenths) of physical impairment, but irrespective of future earning power; (3) to grant supplementary pensions to disabled men or widows in addition to the normal scales where the man's status, judged by his pre-war earnings, indicated that the normal pension would be inadequate. A further revision was found necessary in 1918, largely owing to the increased cost of living due to the depressed purchasing power of money, and for the same reason it was found necessary to give further assistance to persons receiving pensions in respect of service in previous wars. After the armistice the whole position was reviewed by a Select Committee of the House of Commons set up to inquire and report upon the past method of administering the pensions acts and warrants and what steps, if any, were necessary for the removal and prevention of legitimate grievances. The committee recommended that special tribunals should be set up for the hearing of appeals as to title to, or amount of, pensions, such tribunals to be independent of the Ministry of Pensions, and their decision to be final and binding on both the Ministry and the appellant. With regard to the scales of pensions the committee recommended that these should be increased to meet the high prices then obtaining, and that power should be taken to increase or decrease the scales periodically as the cost of living rose or fell. The plan was adopted in a new warrant (Cmd 457 of 1919), but though the cost of living dropped very materially in subsequent years no adjustment of pensions was made. The following specimen rates taken from the warrant of 1919 represent the minimum weekly pensions applicable to a soldier whose disability is of the highest degree (e.g. loss of two or more limbs, total loss of sight, &c.): 40s. if single, 50s. if married, with an addition of 7s. 6d. for the first child, and 6s. for each subsequent child. The widow of such a man receives 20s. if not over forty and without children eligible for an allowance, or 20s. 8d. if over forty or with children, the allowances for children being 10s. for the first, 7s. 6d. for the second, and 6s. for each additional child. On remarriage the widow's pension ceases, but the children's allowances continue, and the widow is given a lump sum equivalent to one year's pension.

The arrangements referred to above, under which alternative pensions based on the disabled, or deceased, soldier's pre-war earnings could be claimed, were continued in the new warrant, with the necessary adjustments appropriate to the increased cost of living. In the case of N.C.O.'s, warrant-officers, &c., additions based on the man's rank are made to the scales applicable to privates. For officers the same general principles are involved, but there are important differences in their application. Stated briefly, a disabled officer of the rank of captain or under, whose disablement is of the highest degree, receives a pension of £210 per annum under the warrant of 1920; but where he would be entitled to more under earlier warrants because, for example, he was an officer in the regular army, his case is dealt with according to the more favourable scale. In cases of pecuniary need, additional allowances towards the cost of educating children are granted. Officers of higher rank are granted larger pensions, and proportionately reduced sums are payable to officers whose degree of disablement is less than the maximum. The pensions awarded to the widows of deceased officers are graded according to the rank of the husband and the number of children: for example, the widow of a captain receives £140 per annum, plus £36 for each child.

A disablement pension is at the outset generally a temporary award for twelve months, based on a

medical board's assessment of disablement arising out of injury or disease due to war service; it is reviewed periodically until the man's position has become stabilised, and a final award under the War Pensions Act of 1921 can be made.

The number of claims for pensions grew steadily during the war, until in the year 1919 the Ministry of Pensions had to deal with nearly 700,000 new cases. Up to March 1925 the aggregate number of awards (exclusive of allowances and gratuities for minor disablements) was over 2 millions, and the aggregate number of beneficiaries to whom compensation had been paid was 4½ millions. Owing to deaths, remarriages of widows, attainment by children of the maximum pensionable age of 16, and improvement in the health of pensioners, the number who were in receipt of pension or allowance at that date had fallen to 1,900,000.

Up to March 1925 the total expenditure for war pensions provided out of the Exchequer had amounted to about 600 millions, the cost in the maximum year, 1920, being over 106 millions. In 1923 the annual burden had fallen to 72½ millions, the corresponding figure in 1924 being 69 millions (of which less than 5 per cent. was absorbed in administrative expenses). The cost will diminish year by year as pensions terminate; and it has been estimated that the annual cost will drop to about 52 millions in 1930, 37 millions in 1940, and that it will not fall below 10 millions until after 1965.

NATIONAL OLD AGE PENSIONS belong to a different category, and may to some extent be considered as falling under the treatment of the poor (see POOR-LAW), but dissociated from the stigma and the disabilities of pauperism or workhouse conditions. The problem of the provision of suitable assistance for the aged poor is one which has attracted the attention of the governments of most civilised communities during the last half-century; so far as the United Kingdom is concerned, the question assumed a definite shape in the last decade of the 19th century, public opinion being especially drawn to the matter through Mr Charles Booth's investigations into the causes of the high rate of pauperism in old age. As a consequence, a Royal Commission was appointed to examine this subject in 1895, and was followed by further committees, but nothing was achieved until the Old Age Pensions Act of 1908. Under this scheme, which was admitted by the government spokesman on its introduction to be only a beginning and necessarily experimental, old age pensions at the rate of 5s. a week were granted to all persons (subject to the undermentioned exceptions) aged 70 or over whose yearly means did not exceed £21 (approximately 8s. a week), persons whose yearly means were between this amount and £31, 10s. receiving smaller pensions ranging from 4s. to 1s. a week, and those whose means exceeded £31, 10s. being disentitled to any pension. The scheme was limited to persons who had been British subjects for at least the last twenty years, and who had been resident in the United Kingdom during that period. Persons in receipt of Poor-law relief (other than medical or surgical relief) were excluded from the scheme, and also persons who before becoming entitled to a pension had habitually failed to work according to their ability for their maintenance and that of their dependants—a criterion which in practice has been found difficult to administer. Pensions were withheld also from pauper or criminal lunatics, and from persons convicted to be imprisoned without the option of a fine, while in prison and for a further period of ten years. Under the Act of 1908 the whole cost of the scheme is provided out of the Exchequer; the burden in the first complete financial year was 8½ millions sterling, which by 1916 had grown to 12½ millions. In 1916, owing to

PENSIONS

the high cost of living due to the Great War, additional allowances not exceeding 2s. 6d. a week were granted to pensioners who were suffering special hardship through the war; and in 1917 these supplementary payments were made general, the standard rate of pension being increased from 5s. to 7s. 6d. At the close of the war a Departmental Committee was appointed to consider what alterations as regards rates of pension or qualification should be made in the existing scheme; the committee recommended that the standard rate of pension should be increased to 10s., and that the pension age of 70 should be retained, the cost of a non-contributory pension commencing at an earlier age being in their opinion prohibitive, the effect of substituting age 65 for age 70 being nearly to double the cost. The majority of the committee thought that pensions should be universal, all qualifications as to means being abolished; the minority, however, recommending that the existing means scale should be doubled. By the Act of 1919 the standard rate of pension was increased to 10s., and as regards qualification, the recommendation of the minority was adopted. The means test was further eased by an amending act in 1924; the full scale is granted where, in the case of a married man or woman, the combined means of a married couple do not exceed £139, 10s., or, in other cases, the means do not exceed £65, 5s., but is subject to reduction if the income of a pensioner includes earnings of more than £39. Proportionately reduced pensions are payable where the means are larger, until in the limiting case a married couple with a combined income of £177, 15s., or a single person with an income of £88, 17s. 6d., receives no pension.

The extension of the non-contributory pension schemes since its commencement in 1908 until 1924 had thus been substantial, being hastened by the changed value of money brought about by the Great War; and in view of the financial position of the country, the government decided that further developments, including the reduction of the pension age, for which there had long been advocates, should be financed on a contributory basis. The Widows', Orphans', and Old Age Contributory Pensions Act of 1925 extends the social services provided for the working population by adding to the existing schemes of health insurance, unemployment insurance, and workmen's compensation (see INSURANCE), a scheme of pensions for widows and dependent children, and old age pensions commencing at the age of 65 instead of 70, and passing, on the attainment of the latter age, into pensions under the Old Age Pensions Acts, freed, however, from the restrictions and disqualifications hitherto applied to such pensions. The Act of 1925, which extends to Great Britain, established the new scheme on a contributory and compulsory basis, interlocked with the existing scheme of National Health Insurance, and at its commencement in 1926 there were about 15 million contributors in Great Britain. The rate of contribution is ordinarily 9d. a week in the case of a man, equally divided between the workman and his employer, and 4½d. in the case of a woman, of which 2d. is payable by the employee and the balance by her employer; in addition, the Exchequer makes a substantial contribution, as explained below. The above scales of contributions apply to the first ten years of the scheme (1926-1935), in the following decennium a further 2d. (men), 1d. (women), equally divided between the workman and his employer, will be charged, the scale rising again by similar additions in 1946 and also in 1956; the weekly rate of contributions will thus be 1s. 3d. for a man and 7½d. for a woman from January 1956 onwards. The contributions are collected under the health insurance machinery, a combined stamp

being employed, covering the contribution payable under that scheme and also that under the new scheme; by this arrangement the troublesome complication which would have arisen had an insured person had to carry an additional contribution card and his employers to stamp it weekly was avoided. Persons who, after a specified period of compulsory insurance, cease to be employed contributors on becoming, for example, their own masters, are permitted to continue as voluntary contributors, and this privilege was extended to certain classes who had passed out of compulsory health insurance before the new scheme started, provided that they exercised their option to contribute within the first six months of the scheme; persons are not, however, permitted to be voluntary contributors under the pension scheme alone, but must pay the combined contribution for health and pensions.

Subject to certain qualifying conditions, the benefits provided for contributors are as follows:

- (a) *Widows' Pensions*.—10s. a week for the widow of an insured person, with an additional allowance for children up to the age of 14 (with extension to 16 if undergoing full-time instruction in a day-school) at the rate of 5s. a week for the eldest child, and 3s. a week for each of the other children. In the event of the widow remarrying the children's allowances continue, but her pension ceases.
- (b) *Orphans' Pensions*.—7s. 6d. a week for each child of an insured man, being a married man or a widower, or of an insured widow.
- (c) *Old Age Pensions*.—10s. a week to insured men and insured women between the ages of 65 and 70, and 10s. a week to the wives, aged 65 or over, of insured men who are themselves entitled to pensions. From 70 onwards the pension is continued under the Old Age Pensions Acts, but without the application of the means, residence, and nationality tests.

In addition pensions were given to women who had been left widows before the commencement of the act, if, broadly speaking, their husbands would have been insured persons at the date of death had the contributory scheme then been in existence; but no pension is given to a woman in this class unless she has dependent children, and the pension ceases when the youngest child attains the age of 14½. Similarly pensions are provided for children left orphans before the commencement of the scheme. The widows' and orphans' pensions began in January 1926; for old age pensions at 65 the date of commencement is January 1928; but in the transitional period pensions are provided from July 1926 for certain persons qualified by virtue of past insurable employment, over the age of 70, and for their wives or widows under the Old Age Pensions Acts, but without the requirements of those acts as to means, residence, and nationality.

The act provides for the scheme to be administered by the Minister of Health in England and Wales, and by the Scottish Board of Health in Scotland. A claimant for a pension who is dissatisfied with the decision of the Minister or the Board has ordinarily a right of appeal. Pensions are payable weekly by the Post-Office, and charged to a central pension account, to which the contributions and Exchequer grants are carried, the latter being fixed at four millions per annum for the first ten years of the scheme. Consequent upon the reduction of the pension age to 65 it was necessary to amend the National Health Insurance Act (see INSURANCE), the right to sickness and disablement benefits between the ages 65 and 70 being with-

drawn; in view of this adjustment of benefit rights the weekly rate of contribution payable under that scheme was reduced by 1d. (men), 3d. (women). Consequential amendments of a similar character were made in the Unemployment Insurance scheme.

The financial basis of the scheme is complicated and is fully explained in the Report of the Government Actuary on the Financial Provisions of the Bill (Command Paper 2406). Briefly it may be said that the joint-contribution on the ultimate scale payable after 1955 (1s. 3d. man, 73d. woman) represents the appropriate contribution required from the age of 16 to 65 in the case of a young person entering into employment at the commencement of his career to provide for his old-age pension from the age of 65 to the end of life, and for a pension to his widow—that is to say, the benefits flowing from both the Contributory Pensions Act of 1925 and the Old Age Pensions Acts of 1908 to 1924.

In the case of persons of all ages entering between commencement of the scheme and 1955, and of persons over the age of 16 entering after that year, the contributions are not sufficient to support the benefits, for older entrants indeed they suffice to cover only a small fraction of the benefits. Following the plan adopted for health insurance in 1911, the flat rate of contribution is charged in respect of all insured persons irrespective of age, and the whole of the burden of 'making everybody sixteen' is assumed by the state, the cost of pensions year by year in excess of the contributions collected being defrayed out of the Exchequer. It will be seen from the figures given below that the state charge for pensions, including those payable under the Old Age Pensions Acts, 1908 to 1924, will be very substantial. The capital value of the liability assumed by the Exchequer in respect of persons brought within the scheme at the outset was estimated at 750 millions sterling.

The estimated annual charges on the Exchequer arising under the Contributory Pensions Act of 1925 and the Old Age Pensions Acts, 1908 to 1924, are shown below at decennial intervals:

	YEAR			
	1930.	1940.	1950.	1960
Pensions to:				
Widows and children	15*	26	34	38
Persons aged 65 to 70	14	20	21	21
Persons aged 70 and over	35	46	58	63
Total pensions	64	92	113	122
Contributions	23	30	36	42
Excess of pensions over contributions	41	62	77	80

* Figures in millions of pounds.

It will be observed that the cost is estimated to mount steadily during the next generation. As indicated above, the burden of war pensions is a decreasing charge, the estimated expenditure in 1930 being 52 millions, dropping to 37 millions in 1940, 27 millions in 1950, and 16 millions in 1960. The increase in the cost for civilian pensions thus tends to balance the decrease for war pensions. In a speech of great vision the Chancellor of the Exchequer, when outlining the contributory pensions scheme in his Budget speech, referred in the following words to the association of the new scheme with the wreck left by the Great War: 'I like to think that the sorrow and sacrifice and the suffering have been the seed from which a strong tree will grow, under which perhaps many generations of British people may find shelter against some of the storms of life. It is by far the finest war memorial you can set up to those who gave their lives, their limbs, their blood, and who lost their health or dear ones in their country's cause.'

Summary of Exchequer Cost.—The following

statistics (taken from an official return [Cmd. 2613] presented to parliament in 1926) indicate the cost to the Exchequer in respect of pension services of all kinds, and the increase of such charges since 1914:

	YEAR.	
	1914.	1925.
Pensions charged on Defence Votes	£6,956,000	£16,140,000
Pensions charged on Revenue Votes	1,516,000	3,629,000
Civil Service Pensions (including Consolidated Fund Pensions)...	866,000	1,530,000
Total for State Employees	9,348,000	21,299,000
State payments in respect of:		
School Teachers	244,000	4,522,000
Police Pensions	840,000	2,135,000
Total for State Employees, Teachers, and Police	9,932,000	27,956,000
Old Age Pensions	10,111,000	26,784,000*
War Pensions		66,484,000
Grand Total	20,043,000	121,244,000

* Due to rise by £5,700,000 in the following year owing to the new Widows and Orphans Scheme.

Pentacle, or **PENTAGRAM**, a stellate pentagon found on old Greek coins, used as a symbol of mystery, perfection, or of the universe by Pythagoreans, Neoplatonists, and Gnostics. It occurs on Abraxas Stones (q.v.), and was used as the device of various secret societies, some of them masonic, and hence appears in ecclesiastical architecture (as at Rouen). The 'wizard pentagram' was, in the middle ages, a symbol powerful in repelling evil spirits, and is familiar to readers of Goethe's *Faust*. On the doors of cow-houses it was held to keep off witches.

The pentacle, also called *pentapla*, is often confused with the hexagram, a stellate hexagon, also used as a magic symbol in astrology, alchemy, and cabalistic lore. See **CIRCLE (MAGIC)**.

Pentacrinus. See **CRINOIDEA**.

Pentadesma. See **GUTTIFERÆ**.

Pentamerone, a famous collection of fifty folk-tales (Naples, 1637), written in the Neapolitan dialect, by Giambattista Basile, which are supposed to be told during five days by ten old women for the entertainment of a Moorish slave who has usurped the place of the rightful princess. Sir Richard Barlow printed a complete English translation in 1893 (2 vols.). The *Pentamerone* stories are of the greatest value to the student of folk-tales.

Pentamerus Beds, in Geology, a name formerly applied to the upper and lower Llandovery rocks, owing to the abundance of the brachiopods called *Pentamerus*. See **SILURIAN SYSTEM**.

Pentameter. See **DISTICH**.

Pentapolis. See **CYRENAICA**.

Pentateuch, a Greek word (*pentateuchos*) meaning 'the five-volume (book)', used by Origen (3d century A.D.) to denote what the Jews of his time called 'the law' (*Torah*). The same word was adopted into Latin. 'The five books of Moses' as a designation of the Pentateuch was first made current in the Western Church at a considerably later period; but the Jewish writer Josephus had long before stated that the first five books of the Old Testament canon 'belong to Moses.' The Greek names by which the five books are now known—Genesis, Exodus, Leviticus, Numbers (Arithmoi), Deuteronomy—have come to us from the Septuagint through the Vulgate Latin. The Mosaic authorship is nowhere affirmed in the books themselves, but it is suggested by certain obvious phenomena in various parts of them, though contradicted by others; and it had begun to be held before the Jewish canon was closed ('the law of

Moses,' Dan. ix. 11, 13; 'the book of Moses,' 2 Chron. xxv. 4, xxxv. 12). It soon became a fixed ecclesiastical tradition and a tacitly established point of Christian orthodoxy, and those who doubted or denied it were generally held to be hostile to Christianity. The facts which have led scholars to a contrary conclusion have already been indicated; see BIBLE, BIBLICAL CRITICISM (vol. ii. p. 121, col. 2; and p. 134). It is there seen that the Hexateuch (i.e. Pentateuch and Joshua) is of composite origin; that, in *their present form*, D (Deuteronomy) is commonly ascribed to a date not earlier than the 7th century B.C., and P (the 'Priestly' narrative and legislation) to the 5th, while the remaining sources J and E ('Yahwist' and 'Elohist') are regarded as undoubtedly very much earlier, but several centuries later than the events they describe. This important conclusion, dating from about the seventies of the last century, is bound up with an entire reconsideration of the ordinary view of the Old Testament, and, though attacked from time to time, has never been seriously shaken.

Such are the many inconsistencies, and the differences of historical, social, ethical, and religious standpoint, that the composite character of the Hexateuch is undeniable. D and P can be pretty easily recognised and approximately dated, but the problems of JE are more intricate. On the one hand it has been found necessary to regard both J and E as themselves composite, or to postulate a third old source. On the other hand some writers, under the divine names, by reason of their different nature (Elohim, 'God' in general; Yahweh, the national God of Israel) and the variant renderings in the Greek MSS., are no sound criteria of diversity of source. Against this, however, it must be observed that the divine names, a very conspicuous clue in the early days of biblical criticism (from 1753), led to the discovery of other clues, the superior importance of which is proved by—to mention only one fact—the subsequent recognition (1853) that there were two distinct 'Elohistic' sources, the later being that which is now styled 'E'. It is true that the theory of the main sources J E D P and of their relative dates (very no means to be considered as final in all its details), but it provides a starting-point. So numerous and striking are the indications of diversity of authorship, *modus*, and date that some adequate hypothesis is imperatively demanded; and no other has as yet made its appearance. It may be added that if, as is sometimes conjectured, some portion (at least) of the Old Testament was originally in cuneiform (Babylonian or Assyrian), the internal peculiarities would still require explanation, alike whether they are supposed to be due to the translator from cuneiform into Hebrew, or were already present in the presumed cuneiform original. Finally, since conservative writers generally allow that the Pentateuch, though 'substantially Mosiac', has received some late alterations, and since one ancient tradition even ascribed to Ezra (5th century B.C.), the rewriting of the Law, the Pentateuch in *its present form*, is obviously the safest starting-point, although on the antiquity and value of its several contents there will naturally be wide divergence of opinion.

Modern research in the 'lands of the Bible' has thrown remarkable light upon the position of Palestine and its highly developed neighbours, the antiquity of its own civilisation, and the extremely close relationship between the beliefs and practices of the Hebrews or Israelites (the latter a narrower term) and those of other peoples in Babylonia and Egypt. There were ethical ideas and elaborate laws before Moses, and the code of the Babylonian king Hammurabi (c. 21st century B.C.) finds many parallels in the Old Testament. Jerusalem itself had an interesting religious history before the Temple was built, and the Amarna Tablets (c. 1400-1350 B.C.) testify to well-organised religious ideas in Palestine before the entrance of Israel. There are numerous traces in the Old Testament of external influence, but the borrowers set their stamp upon all they received; and the more closely Palestine is linked by external evidence with other lands, the more conspicuous becomes the independence of the Old Testament. Of the Hyksos kings in Egypt, their expulsion, and the numerous Egyptian campaigns in Palestine (see vol. iv. p. 241), the Old Testament writers have no certain knowledge; the few traces that have been conjectured (e.g. associating the patriarchs with the Hyksos) would, at the most, only emphasise the gulf between the facts revealed by ancient or contemporary evidence and the writers' recollection of them. No one can deny the probability of invasions like that described in Gen. xlv., but, as the chapter now reads, there are details which make it untrustworthy as a historical document. It is still difficult to find external evidence for the Exodus, though one doubts that the Egyptians employed Semitic slaves, and that tribes could enter Egypt and return to Palestine. But since the incisive criticism of Bishop Colenso the untrustworthy nature of the biblical record has been increasingly recognised, and recent excavations in Palestine have refuted the sweeping conquests ascribed to Joshua. The

indubitable antiquity of writing does not prove the antiquity of our records, and the Pentateuch simply does not reproduce the history and conditions of the second millennium B.C. as we now know it from independent sources. The Old Testament has its own way of describing the past, and although it has undoubtedly preserved many genuine facts, its point of view stands as much in need of explanation as do the internal inconsistencies.

The religious uniqueness of the Old Testament, which gives it its permanent value, begins with the opening chapters of Genesis; that is to say, it characterises the *description* of the earliest history. It is a religious account of beginnings, due to the writers, and the problem of the Pentateuch turns on the study of this standpoint. There are remarkable differences between the account of the monarchy in Samuel-Kings and that in Chronicles, between the patriarchal stories and what is said in the late Book of Jubilees and Testament of the Twelve Patriarchs (c. 1st century A.C.), and equally between JE and P, and, finally, even between J and E. These differences are bound up with the internal history of Israel, and to understand them attention must be directed primarily, not so much to the question of the ultimate facts of history, as to the evident interests, aims, and scope of the writers. The later writings alone suffice to prove that certain names and details may be very much older than the context in which they now appear (e.g. the accounts of the patriarchs in Jubilees); and 'literary-historical criticism,' or the analytical study of the descriptions of the past, throws no little light upon the developments of life and thought at the time when, as it would seem, the narratives were taking shape.

The problem of the growth of the Pentateuch is intertwined with that of the teaching of the great pre-exilic prophets and with post-exilic Judaism. With Deuteronomy is connected both the account of the discovery of the Law-book in the reign of Josiah (c. 621 B.C.) and a characteristic 'Deuteronomic' treatment of the following books (Joshua-Kings). Not only is the latter of the 6th century (if not, in parts, later), but Deuteronomy itself is composite, and should probably, as some scholars think, be assigned as a whole to the 6th rather than the 7th century. Now, while behind D can be seen the influence of the prophets, we reach later a specifically 'priestly' tendency (5th century) with which are associated the P portions of the Pentateuch. P as a whole comes after D and before the age of Chronicles, where, in contrast to Samuel-Kings—and also to JE—there is a very striking priestly and levitical tendency. Finally, the 'priestly' phase precedes the 'wisdom' literature (e.g. Proverbs, Ecclesiastes), which reflects the Greek age. Consequently, the Pentateuch cannot be viewed apart from other portions of the Old Testament which, though they deal with other periods of history, date from the periods vital for its growth; and the historical and religious development of Palestine and the stages in the rise of the Old Testament form a single problem.

The middle centuries of the first millennium B.C. constitute the really great creative age in Palestine—and elsewhere. In history we pass from the fall of the Northern Kingdom (c. 722 B.C.) and that of the South (586), over the Exile, to the Return permitted by Cyrus the Persian (537). The rebuilding of the Temple under Zerubbabel (520-516) is followed by a strange blank, until we reach the reorganisation under Ezra and Nehemiah (the latter [c. 445] probably preceding the former), and finally the Samaritan schism. Meanwhile, we pass from the great condemnatory and rather iconoclastic prophets and the striking individualistic tendencies of Ezekiel—and more especially Jeremiah—to the unnamed prophet of consolation and reconstruction (Is. xl. sqq.) and at length reach a distinctively priestly régime. From threat, confusion, and national decay we pass to a new nationalism. Yahweh, Israel's God, no longer punishes a disobedient people, but is Israel's Redeemer. Jerusalem and the Temple, no longer the centre of an unspiritual cult, are the seat of Israel's universal religion, and the more ethical and anti-ritual tone of the early reforming prophets gives way to one more priestly and ritualistic. What at first seems to be a reaction, after the teaching of the prophets,

can now be recognised as the transition from individualistic ethico-religious teaching to the establishment of a more national and systematised type of religion. So, while the earlier prophets taught the character and demands of Yahweh, the later step was the education of the people, and D already reflects the tendency to a 'book religion' which ultimately made Israel, under the law, the 'people of the book.' Unfortunately it is impossible to sketch the development save in the broadest outlines. Place has to be found for the fact that in the 'Second Isaiah,' and notably in the idea of the suffering 'Servant of the Lord,' the religion of Israel reached its high-water mark, a clear sign of internal (though as yet unknown) vicissitudes obviously of supreme significance. Further, in the little-known figure of Zerubbabel there is, as is shown by the contemporary prophets Haggai and Zechariah, a 'Messianic' figure (see MESSIAH), and a new monarchical movement, which, however, collapsed. It is noteworthy that in various passages, independently ascribed to about the 6th century, the monarchical idea recedes into the background, and it appears to be viewed with suspicion (note the subsequent allegation against Nehemiah, vi. 7). On the other hand the priestly idea gains in strength, and ultimately the high-priest, as regards dress, function, and position, is virtually the successor of the former kings, and the priestly religion of the Pentateuch presupposes a prior monarchical régime.

Along with these sweeping changes must be noticed the far-reaching importance of the same centuries for the world's history and religion. Great religious founders and movements of permanent significance can be traced in China (Laotse and Confucius), India (Buddha and Mahavira), Persia (Zoroaster), and Greece. Palestine has the 'Second Isaiah.' It was a new stage in the history of religion, especially marked by the appeal to the individual rather than to the tribe or nation. The map, too, was being redrawn. No longer Babylonia, Assyria, and Egypt hold the field; it is the age of Persia, Greece, and Rome that now dawns. The old Egypto-Semitic world was breaking up, and only in Palestine can an effective continuity be traced. It prepared the way for Christianity. So, while Assyria fell (612 B.C.), with amazing swiftness, and in Egypt and Babylonia there was a strange and sterile reversion to the past, Israel underwent a successful reorganisation, and the inauguration of post-exilic Judaism associated with the work of Nehemiah and Ezra throws into clearest relief the fundamental problem of the Pentateuch. Either it is (on the traditional view) a reassertion of the Mosaicism of many centuries previously, the reintroduction of ancient writings, more or less untouched by the epoch-making changes which had intervened—even as Josiah is supposed to reintroduce the long-lost book of Deuteronomy (2 Kings, xxii. sq.); or (on the critical view) we have a combination of new and old, a reshaping of older law and tradition, with the addition of new regulations, a composition the precise character of which is slowly being determined.

Thus, on the modern view, the Pentateuch covers the close of one chapter of religion and history and the beginning of another, the break-up of one era and the dawn of a second. Such were the internal, social, and political vicissitudes that it becomes increasingly difficult to determine how much dates from the distant pre-monarchical age of Moses, Joshua, and the Judges. It is easier to understand the stages *after* the Pentateuch was once complete than the prior steps. Although all critics agree that the older portions (JE) date several centuries after the events they relate, it now becomes questionable whether *as a whole* they may safely be dated even as early as the 9th and 8th centuries

—that is, before the great changes began. The prophets, it is true, refer to the early history of Israel, but it does not follow that they knew the traditions in their present form; on the contrary, they presuppose the existence of an unspiritual religion, gross and cruel cults, and ideas and usages more in harmony with the surrounding religions, and with what external evidence would lead us to expect, than with the general religious conditions as described (in Genesis-Judges), or with the ideas which evidently actuated the writers. Indeed, JE, although it has popular, naive, and primitive ideas, represents a Yahwism which stands in contrast to the old religion both of the people and (as Josiah's reforms show) of the state. The features which seem to be below the spirituality of the prophets do not necessarily imply that the writers lived before the age of the great reforming prophets; they can be best explained as due to the usual compromise between 'higher' and 'lower' religion, and to the adjustment of the lofty teaching of the prophets to the masses—as can be paralleled elsewhere. Primitive ideas are in themselves no proof of antiquity, and the disintegration and confusion in and about the 6th century B.C. account for many features which otherwise seem to be a sign of early date.

In spite of various striking differences between JE, D, and P, the Pentateuch has a unity, a religious unity. A very close relationship between JE and P was recognised in the early days of Old Testament criticism, when P was dated *before* the other sources (vol. i. p. 134, col. 1). Conservative writers, too, justifiably emphasise the probability of a 'practical contemporaneity of authorship,' a 'co-operation between different writers'—though at an impossibly early date. In fact, if the different sources are more nearly contemporary, and JE *in its present form* does not precede the great prophets, JE may be regarded as one of the bridges between the reforming individualistic uncompromising prophets and the post-exilic priestly régime (P). Without P the teaching of the prophets would hardly have been preserved. But some bridge there must have been, and the higher religious ideas that are worked into JE do not lead up to the prophets but, rather, flow from them. The ethical reformers succeeded in purifying the gross and unspiritual religion which they constantly condemn and which has left its traces in the Old Testament, and the Pentateuch, as a whole, is the result. The Pentateuch in its present form represents only the last stage in a very intricate process of growth, although the non-canonical Jubilees and Twelve Patriarchs survive to prove that the patriarchal and other traditions continued to be further developed and reshaped.

The Pentateuch was the first part of the Old Testament to become canonical and to be translated into Greek. It is inextricably connected with the books that follow, and Genesis-Kings find, to a certain extent, a parallel in Chronicles-Ezra-Nehemiah. With Ezra-Nehemiah placed, contrary to the historical order, before Chronicles, the Jewish Bible ended, not with a hint of the Samaritan schism (Neh. xiii.), but with the idea of the restoration of the Jews (2 Chron. xxxvi. 23), a far more inspiring impulse for a scattered people. The connected narrative 2 Samuel ix.-xx. and 1 Kings i. sq. has been broken by 2 Samuel xxi.-xxiv., and both Josephus and the Lucianic recension make the main division at 1 Kings ii. 12. The end of Joshua and the beginning of Judges overlap (Josh. xxiv. 29, Judg. ii. 8), and although the books of Deuteronomy and Joshua are most closely related, the break is made after the death of Moses. Joshua ends with a meeting of all the tribes at Shechem, the ancient Samaritan holy city and with a solemn covenant and law-giving (Josh. xxiv.); but although the north is prominent in Deuteronomy (cf. xi. 26, xxvii.), it is the single central sanctuary at Jerusalem to which D as a whole now points, and the Pentateuch is, in a sense, less 'Samaritan' than the Hexateuch. Relations between Judah and Samaria were variable. An anti-northern spirit appears in the account of the rise of the monarchy, where Saul is rejected in favour of David, and in the attitude in Kings and Chronicles to the scheming Jeroboam and his successors—although the Yahwism at Jerusalem prior to Josiah's reformation could scarcely

afford to throw stones. It reappears, perhaps, in the slight attention in Joshua to the cities of the central tribes, also in the attack upon Shechem (Gen. xxvii), and in the view that Jacob left his idols there before journeying to Bethel (xxv. 4). In Gen. there is a greater interest in Judean and S. Palestinian matters, and little is told of the northern tribes. Again, although Judah is reckoned one of the 'sons' of Israel, and the passage in Deuteronomy xxvii. 7 regards him as severed from his 'brethren', the Judean history characteristically emphasises the fall of the northern kingdom (Judah and Israel being rival states) and the exile of the ten tribes, as though Judah was the sole representative of the true Israel; whereas to both Jeremiah and Ezekiel the north was as truly Yahweh's as was Judah, if not less sinful (Ezek. xxiii.). Unless the north had accepted Deuteronomy it would hardly have taken, as it ultimately did, the whole Pentateuch—the Samaritans have their own traditions of the heroic Joshua—but the Pentateuch seems to have undergone a special revision after it was separated from the book of Joshua and before it was received by the Samaritans, and consequently the fluctuating relations between north and south, although extremely difficult to trace historically, are very important for the literary history of the Pentateuch and the rest of the Old Testament.

The centre of the Pentateuchal problems lies in Exodus, xxxii.-xxxv. (JE). Here Moses, descending from Sinai (Horeb) with the Decalogue, incensed at the worship of the golden calf, breaks the tables of stones; but, later, after interceding successfully on behalf of the people, returns to the mount in order that the Decalogue may be rewritten. But (a) in Exodus xxiv. 10-28 we have, instead, another series of laws, with parallels in Exodus xxi.-xxiii. and partly of a more ritual, more primitive and less ethical character. (b) The JE section is separated by P from other JE passages, viz. Numbers x. 29-36, xi. sqq. (the journey from Sinai, the election of elders to relieve Moses) and Exodus xxiv. (the elders at the solemn meeting on Sinai), with both of which it is closely connected (in Exodus xxxii. 12 Moses seeks help, cf. chap. iv. where the Levite Aaron is appointed). (c) The tent of meeting, at which the elders receive the divine spirit (Num. xi. 29), is described in Exodus xxxii. 7-11, a simple structure, entirely different from the elaborate tabernacle that characterises P. The account of the latter (which replaces some earlier and fuller account of the tent), is given in Exodus xxxv.-xl, which supplement the instructions to Moses in Ex. xxxi. (contained in Leviticus xvi.-x.). (d) As for the rest of P, Leviticus xi. (sacredness of life) and xii. (laws of uncleanness, &c.) are characterised by the idea of Yahweh's 'holiness', and in xvii.-xxvi. a distinctive body of laws has as its central idea the holiness of the people to conform with Yahweh's holiness. The latter section is styled by critics H (the Law of Holiness), and may be said to contain the theory of the 'holiness' relationship between Yahweh and Israel and all it implied. (e) Corresponding to this in JE is the insistence upon Yahweh's holiness, against which not even Moses and Aaron might offend (Num. x. 12, 24), and the idea of Israel as a kingdom of priests and a holy people (Exodus xix. 6) 'holy' in Numbers xii. 29. Israel as a nation of prophets. But there are strange stories of jealousy and privilege in Numbers vii. and in the markedly composite xvi. where P deals with a strife (1) between Levites and non Levites, and (2) between Aaronite Levites and other Levites. The insistence upon spiritual prerogatives is noteworthy, and (f) P in Numbers i.-x. (censurings for Levites to assist in the priestly office) regards the Levites as a bulwark (Numbers i. 53) to protect the people from offending against the divine majesty (cf. J's idea in Exodus xix. 21, 26). P thus leads up to the journey from Sinai (described by both JE and P, Numbers xi. sqq.). (g) The selection of the Levites comes, according to JE, after the worship of the golden calf (contrary to the Decalogue, Exodus xx. 3 sqq.); with their force zeal may be compared the reforms of Jehu and the Rechabites (2 Kings x.). But the calf-cult, here associated with Aaron, and elsewhere with the first king of the schismatic north (cf. 1 Kings xii. 28 with Exodus xxxii. 4), was once as orthodox as must have been the brazen serpent which so long remained the symbol of the south (2 Kings xv. xxvii.). (h) Moreover, elsewhere the selection of the Levites is associated with the very place where both Moses and Aaron incurred Yahweh's wrath for their failure to respect his holiness (Deut. xxxii. 51, xxxiii. 8 sq.). The place, it would seem, was Kadesh, the original scene of the older traditions. (i) The present narrative of the journey to Sinai (Ex. xxi.-xxvii.) belongs, on internal grounds, to the stage after Sinai; the subject-matter is related to the account of the journey from Sinai to Kadesh (Num. xi. sqq.), and such is the original importance of Kadesh that the present prominence of Sinai (Horeb) and the Decalogue belongs to quite a later stage in the development of the traditions.

(2) There are traces of the description of a separate journey of Israel from Kadesh northwards to Palestine (the victory, Num. xxi. 1-3). With this can be connected an important group of traditions associating Judah and south Palestine. All have been mutilated, and adjusted to the account of the circuitous journey which commences in Joshua's invasion and in the appearance, in the south, of the tribes of Judah and Simeon (Judges i.). For this detour the defeat of Israel at Hormah (Num. xiv. 45) prepares the way, and, among other adjustments, Caleb, an independent figure of semi-Edomite origin, afterwards found at Hebron, is subordinated to both Judah (Judges i.) and Joshua (Josh. xiv.). Further (3) there are a number of striking parallels between the account of the entrance of the tribes of Israel under Joshua and traces of a tradition of the entry of the

sons of Israel (Jacob) and their settlement (cf. Jacob's conquest of Shechem, Gen. xlviii. 22). Finally (4) The story of Joseph seems to link together the traditions of a conquest and settlement (almost wholly lost) with those of a descent and a re-entry after the exodus from Egypt. On a variety of grounds it is clear that not all Israel left Palestine and returned, but the Joseph-tribes (central Palestine) seem, to judge from the story, to be specially connected with Egypt; and whereas the Israelites could leave Egypt to bury Jacob and return again, the removal of Joseph's bones is one of the motifs of the exodus (Gen. i. 25, Josh. xxiv. 32).

The account of the patriarchs, the descent into Egypt, the exodus, the law-giving at Sinai, and, finally, the conquest of Palestine by Joshua has been seen to represent only a relatively late view of the early history. Behind the Pentateuch are traces of lost traditions of quite another stamp. Something was known of the Nephilim, a Titan-like race (Gen. vi. 4; Num. xiii. 33), a tradition of a familiar type, but quite out of place in Gen. i.-xi. Like the accounts of Cain and Abel, and the beginnings of civilisation, it virtually ignores the story of the Deluge; while, behind the story of Lot, the destruction of Sodom and Gomorrah, and the origin of Moab and Ammon (Gen. xix.), there is another tradition of widespread destruction, but differing in spirit and ethnological interest from that of the Deluge. That the worship of Yahweh began with Enosh ('man'), the grandson of Adam (Gen. iv. 26), could only belong to some curiously independent tradition, and if, as some data suggest, Yahweh was closely associated with the Kenites (Cain), the clan of Moses' father-in-law, and with the Midianite and other peoples of South Palestine, the question arises whether the Kenites and related clans actually introduced the worship of Yahweh into Palestine, or (more probably) were responsible for a new stage in the history of Yahwism. New religious influences were due to the clans from the desert no less than to the prophets, but even after the age of Elijah (note his visit to Horeb, the mount of God, 1 Kings, xix.) such influences upon the religion may be expected both when Sargon introduced nomad tribes (partly Midianite) into Samaria in 715 B.C., and later, from the references to active movements among desert tribes in and about the 6th cent.

The Pentateuch as a whole, with its descent into Egypt and its exodus, quite ignores the standpoint of those who remained behind in the land. The true Israel went down as 'sons' and re-entered as 'tribes' (Gen. xli. i; cf. Num. xxvi.). Similarly the history of the fall of Jerusalem and the Return from exile in the 6th century is indifferent to the standpoint of those who did not participate in it, and Ezra ii. purports to be the list of men who returned 'to Jerusalem and Judah, each man to his city.' But the value of this list is doubtful, and critics tend to the view that the native population was not negligible, and may even have built the temple under Zerubbabel. The most important return of exiles came later, in the age of Nehemiah and Ezra. Moreover, not only is the anticipated return of exiles regarded as almost a second exodus (Is. xl. sqq.), but the Pentateuch had not yet received its present form, and the traditions of the exodus itself must have been in a fluid state. The Pentateuch gains immeasurably in significance when its growth is associated with those middle centuries of the first millennium B.C. during which a people, amid great political and social confusion, were moving towards a 'Promised Land', and the unknown prophet of Is. xl. sqq. was heralding a new age. Some stages in the development can perhaps be recognised. Instead of the laws of the old kingdom, with all its commercial and military interests, we have those of a simple agricultural life. There is, notably in D, a striking appeal to religious and humanitarian feelings. A new public opinion is in course of formation, a new era is

inaugurated by special covenants. The popular stories (JE) point to a people who are being instructed in their place in history, in the origins of their race, their institutions, and their sanctuaries. Ideas of divine care and providence and the inculcation of kindness and hospitality are set forth in stories behind which can be discerned the traces of an obsolete culture. The God of Israel was directly interested in his own people; no people ever had such a God, nowhere else was the link so intimate. Israel was his own treasure (Exod. xix. 5). But there were duties as well as privileges, and Israel's destiny entailed discipline. Democratic in its spirit as the older religions standpoint is, we become conscious of another note when men must not put their God to the test (Deut. vi. 16), as, for example, a Gideon and even an Abraham had done (Judges vi. 36; Gen. xv. 8). People and leaders alike must respect God's holiness; and Israel, theoretically a holy people and a nation of priests (Exod. xix. 6; cf. Num. xi. 29), needs the mediation of the priesthood, and there is a representative sacred caste to keep the people from the sacred altar. There is a perceptible transition from confidence and joyousness (JE) to a certain restraint, if not timidity (P). The sense of sin and the need for atonement become very striking. The priest atones and performs the necessary ritual for the removal of guilt. The priestly ritual expressed the new consciousness of sin, but did not create it; and the highly developed sacrificial system, with its atoning value, seems to come after Is. liii., if it is not powerfully influenced by the circumstances behind that chapter. In the Second Isaiah (ch. xl. *sqq.*) extravagant hopes of a new age give way to disillusionment; and Is. liii., with its mysterious allusion to the atoning death of some human victim, is the echo of some shock, though the historical background (c. 500) is quite unknown. Moreover, men told of the world-wide Deluge, the result of man's wickedness, and the confident attempt to storm the heavens (Gen. xi.); Yahweh's sanctity was attacked (as in the story of Eden, Gen. iii. 5), and mankind was scattered, and the history of the chosen people begins with Abraham (Gen. xii.). Men had sinned, and the Deluge swept the earth; but God would no more destroy life (Gen. viii. 21 *sq.*), even as he would no more forsake, as he had forsaken, his people Israel (Is. liv. 7-10; Jer. xxvi. 35 *sqq.*). Ideas of this sort, suggestive of some false start after an age of turmoil, and woven into the history of an exclusive Israel, dwelling amid heathen Canaanites and possessing an elaborate priestly system, point indubitably to definite historical vicissitudes, though at present they can hardly be conjectured.

The Persian age was cosmopolitan and syncretistic, and the inauguration of Judaism was the victory of the narrower and more exclusive Jews to whom Persian tolerance, and the tempting identification of the Eschate Yahweh and the highly ethical Persian god Ahura-Mazda—in the Greek age it was to be Zeus—would be anathema. There might be a world-wide Yahweh, a religious universalism (Mal. i. 11), but Jerusalem must be the centre (Is. n. 3), and extreme intensive steps were the road to any extension of the new Judaism. There are signs of different sorts of exclusiveness in the later parts of the Pentateuch, and in the steps taken by Nehemiah (viii. 1) and Ezra (x) to purge the community. There are also hints of priestly rivalries (e.g. Mosesites and Aaronites), though the elevation of the Jerusalem Zadokites over other Levites, as ordained in Ezekiel xlv., and as represented in the account of the rise of Solomon (1 Kings I.), was complete before the Pentateuch was finished. But there are traces of compromise among the priests; and the Pentateuch, like the Old Testament itself, with its varied contents and differing points of view, is no less a compromise. It shows by its composite character that it has passed through several hands; and, although the last were priestly, it combines the popular and the priestly, the hordic and the legalistic, like the Midrashic and Mishnaic elements in the Talmud. It contained, at least in germ, all that Israel needed: a canonical history (cf. Neh. ix; Ps. cv.); it was the source of its theology and (in Alexandria) of its philosophy. Men idealised the temple (Ps. lxxxv. 10), the sacrificing priest (Ezekiel I.), and the Torah itself (Ps. cxix.). The Law (Torah)

gave Israel a norm. There was freedom within it when it was approached through the prophets, but when the emphasis was laid upon the letter and the prophets were forgotten, it could be and was deadening. So, in the age of Greek syncretism, when Zeus was the rival of Yahweh, the Maccabean revolt, animated by the spirit of the Torah, gave a fresh impulse to Judaism, but deteriorated as it passed from fiery enthusiasm to fanatical zeal.

Accordingly, the genius of Israel manifests itself not only in the prophets of Israel—and especially the writers of Isaiah xl. *sqq.* and the unknown figure behind Isaiah liii.—but also in the authors of the imperishable charming narratives of the Pentateuch, and in the fine constructive work which marks the Pentateuchal history as a whole. Not as some pre-monarchical epic of the 14th and 13th century B.C., but as the outcome of a period of immense significance for ancient history and religion (7th to 5th century B.C.), it embodies some profound developments which, however, cannot as yet be clearly traced. The pregnant ideas which live in its narratives were the living experiences of a fateful period; and just as the prophets had implied that men already knew of themselves the Law of Yahweh, so, when the Torah was composed and promulgated, it presents itself as ostensibly of ancient origin. But it was so fundamental a reshaping of the old that it gave new life to an old land in a way that an authentic work of bygone centuries could never have done. Thus it came to pass that in striking contrast to Egypt and Babylon, with their conscious archaism, in Israel alone we find continuity and reconstruction, and (in the words of the chief founder of the modern position in Old Testament criticism), 'The Mosaic history is not the starting-point for the history of ancient Israel, but for the history of Judaism' (Wellhausen).

The Pentateuch holds the central place in the study of the Old Testament; see the literature, vol. i, p. 129. Besides the 'introductions' by Driver (9th ed. 1913), Cornill (1907), Sellin (1923), and the special works on the Pentateuch by A. T. Chapman (1911) and D. C. Simpson (1924), see especially the annotated translations by Addis (1892-98), Kent (1904), and especially Carpenter and Haiford-Battersby (1900). The best conservative work is J. Orr, *Problem of the Old Testament* (1905). Among special studies are those of Meyer and Luther (1906) and Smend (1912), both in German; for special points see S. A. Cook in *Camb. Anc. History* (vol. n, chap. 14; vol. m, chap. 20).

Pentecost (Gr. *pentekostē*, 'fiftieth') was the name given to the Jewish feast held on the fiftieth day after the Passover, in celebration of the 'ingathering,' and in thanksgiving for the harvest (see FESTIVALS). From the Jewish use it was introduced into the Christian, and with special solemnity, as being the day of the descent of the Holy Ghost on the apostles, and of the first solemn preaching of the Christian religion. From early times pentecost has been regarded as one of the great festivals of the Christian year, and it was chosen as one of the times for the solemn administration of baptism; and the English name of the festival, *Whit-Sunday*, is derived from the *white* robes in which the newly-baptised were clad. It is regarded as specially sacred to the Third Person of the Blessed Trinity. Many curious usages were anciently connected with the celebration. The figure of a dove (an emblem of the Holy Ghost) suspended by a cord from the ceiling was in some churches lowered so as to alight on the high altar during the service; in others figures of cloven tongues were similarly introduced. In some places in the East, and in the West too, the practice prevails of decorating the churches with evergreens and flowers, as is done in England at Christmas.

Pentelicus. See ATHENS, and MARBLE.

Pentland Firth, a channel between the Atlantic and German Oceans, separating the main-

land of Scotland from the Orkney Islands. It is 14 miles long and 6½ miles broad at the narrowest. The Pentland Skerries, 5 miles north-east of Duncansby Head, consist of two islets and of several contiguous rocks. The navigation of the Pentland Firth is more dangerous than that of any other portion of the Scottish seas, a current from west to east flowing through it with a velocity of from 3 to 10 miles an hour, and causing numerous eddies and whirlpools.

Pentland Hills, in the Lowlands of Scotland, extend 16 miles south-westward from within the burgh boundary of Edinburgh, through the counties of Midlothian, Peebles, and Lanark, have a breadth of 4 to 6 miles, and attain a maximum height in Carnethy (1890 feet) and Scald Law (1898). In the battle of the Pentlands or Rallion Green, 2 miles NNW. of Penicuik, Sir Thomas Dalrymple routed 900 westland Covenanters, 28th November 1666.

Pentonville, a populous district in London in the borough of Finsbury, the first buildings in which were erected in 1773 on fields belonging to Henry Penton. The name has since been extended to part of Islington, in which in 1840 42 *Pentonville Prison* was built on the radiating principle, so as to admit of thorough inspection.

Pentremites, fossil Crinoids common in the Carboniferous System (q.v.).

Pentstemon, an American genus of Scrophulariaceae, consisting of herbaceous or sub-shrubby species mostly yielding flowers of great beauty. Few of them are hardy enough to endure the winter climate of Britain, where consequently they are propagated annually by cuttings, which are protected in frames during winter and planted in the flower garden in March or April. The numerous garden varieties of *P. gentianoides*, *P. Hartwegii*, and others are among the most popular of garden flowers. But there are many species even more beautiful than these, which are occasionally to be met in collections of rare plants. Of such may be mentioned *P. azureus*, *P. secundiflorus*, *P. Murrayanus*, *P. minimus*, *P. laevis*, found from Florida to Pennsylvania, deserves to be planted by beekeepers wherever it would grow.

Penumbra. See ECLIPSES.

Penza, a large rural town of Russia, 330 miles by rail SE. of Moscow, has a cathedral (17th century), a botanical garden, and manufactures of paper, soap, &c.; pop. 80,000.

Penzance, a town of Cornwall, the most westerly in England, at the head of Mount's Bay, 10 miles ENE. of Land's End. Standing on a finely-curved shore surrounded by rocky eminences, it is famous for its mild, equable climate, though the annual rainfall is heavy (43 inches). Its fine esplanade commands splendid land and sea views; and its chief buildings, constructed largely of granite, include a market-hall (1837) with a statue before it of Sir Humphry Davy (q.v.), an infirmary (1874), a post-office (1883), and public rooms (1867), Italian Renaissance in style, and comprising a guildhall, museum, library, &c. The harbour has two piers (1772-1845) half a mile long, forming a tidal basin of 21 acres; and docks. Mackerel and pilchard fisheries, market-gardening and flower-growing are important industries. Much in favour as a watering-place, Penzance has regular sailings to the Scilly Islands. Burned by Spaniards in 1595, and sacked by Fairfax in 1646, it was incorporated in 1814, and from 1663 to 1838 was one of the five 'coinage towns.' Pop. 12,000.

Peonage, a system of agricultural servitude common in Mexico (q.v.) and some other parts of Spanish America. The peón in debt to his employer was by the Spanish colonial system bound to labour for his employer till the debt was paid.

Peonage in New Mexico was abolished by act of congress in 1867. Formally abolished elsewhere, it survives in effect in remote regions.

Peony (*Paeonia*) a genus of Ranunculaceae, with large showy flowers composed of five leafy herbaceous sepals, 5 to 10 petals, numerous stamens, and 2 to 5 carpels, each with numerous round, black, shining seeds. The leaves are compound, the leaflets variously and irregularly divided. The fibres of the root are often thickened into tubers. The species are large herbaceous perennials, or rarely half-shrubby, natives of Europe, Asia, and the north-west of America. None of them are truly indigenous in Britain, although one (*P. corallina*) is undoubtedly naturalised on Steep Holme Island in the Severn. On account of the beauty of their flowers, some of them are much cultivated in gardens, particularly the Common Peony (*P. officinalis*), a native of the mountain-woods of the south of Europe, with cambric or blood-red flowers. A variety with double flowers is common. The White Peony (*P. albiflora*) is another favourite species, of which there are now many beautiful varieties which have originated in French and Belgian gardens. It is a native of the central parts of Asia. Its flowers are fragrant. The Tree Peony, Chinese Peony, or Mountain Peony (*P. Moutan*), is a half shrubby plant, a native of China and Japan. In favourable circumstances it attains a very large size, and a height of 12 feet or more. It has long been cultivated in China and Japan; and is now also a favourite ornamental plant in the south of Europe, but is too tender to endure the climate of Britain, except in the most favoured parts; it is, however, often to be met with in conservatories, being of a very distinct and ornamental character when in flower. Its flowers in spring. The varieties in cultivation are numerous. It is propagated by cuttings and also by grafting. The roots of most of the peonies have a nauseous smell when fresh, and those of the Common Peony were in high repute among the ancients as an antispasmodic—hence the name Peony, from *Paeon*, a Greek name of Apollo, the god of medicine; but their medicinal properties are now utterly disregarded.

Peoria, capital of Peoria county, Illinois, on the west bank of the Illinois River, at the outlet of Peoria Lake, 160 miles SW. of Chicago. It is an important railway centre, and is connected by steam navigation with the Mississippi and by canal with Lake Michigan. It contains a Roman Catholic cathedral, colleges, and hospitals. The streets are wide, and there are many parks, the largest Jefferson (35 acres). Mines of bituminous coal supply the city's numerous and varied manufactures. Much grain is shipped. In the lower city are large stockyards. Pop. 76,000.

Peperino, a variety of tuff, met with in the Alban Hills near Rome. It is dirty grayish brown to white, earthy, and granular, and contains crystals of mica, leucite, ngite, &c., with fragments of limestone, basalt, leucite-basalt, &c.

Peperomia. See PIPEACEAE.

Pepin, or PIPPIN, surnamed 'the Short,' king of the Franks, was the son of Charles Martel and the father of Charlemagne, and founder of the Frankish dynasty of the Carolingians (q.v.). Charles Martel shortly before he died divided his kingdom between his two sons, Carloman and Pepin, Carloman taking the German part, and Pepin the Neustrian or territories in northern France; still they were only rulers (dukes) in the name of the Merovingian king. Carloman, after six years of office or rule, was persuaded by the English monk Boniface to enter (747) the monastery of Monte Cassino; his duchy passed over to Pepin. St

Boniface in 751 crowned Pepin king of the Franks at Soissons, Childeric, the last of the *faînéant* Merovingians, having been deposed and his very able substitute chosen king in his stead. Pepin rested his power in great part upon the bishops and monks; accordingly, when Pope Stephen III. was hard pressed by the Longobards (Lombards) under Aistulf, he came (754) to France to solicit help from the new king of the Franks. Pepin led an army into Italy, compelled Aistulf to become his vassal, gave to the pope the title of exarch (of Ravenna), a title of the Roman empire, and so, by this 'Donation of Pepin,' laid the foundation of the temporal sovereignty of the popes; himself he made 'patrician of the city of Rome'—all this in 756. The church in his own dominions he placed under the supremacy of the pope. The rest of his life was spent in semi-crusading wars. Before going to Italy he had already attempted to convert the heathen Saxons at the sword's point; he went on with the 'holy' work in 757. Then he drove the Saracens back over the Pyrenees (758) and made (760-768) repeated incursions into Aquitania, though he never permanently conquered it. He died in 768, and his sons Carloman and Charlemagne divided his territories between them.—There were other rulers of this name amongst the Carolingians. PEPIN OF LANDEN (died 639), with the help of Bishop Arnulph of Metz, was appointed *major domus* or viceroy of Austrasia under Lothair II.—PEPIN OF HERISTAL (died 714), his grandson, succeeded as mayor of the palace in Austrasia, to this added after 687 the similar vicerealties of Neustria and Burgundy, and called himself 'Duke and Prince of the Franks.' He was their real ruler during the reigns of the puppet kings Theodorie, Ludwig III., Childbert III., and Dagobert III., and fought successfully against the Frisians, the Alemanni, and the Bavarians.—PEPIN, the son of Charlemagne, who was born in 778, was crowned king of Italy in 781, fought against the Avars, the Slavs, and the Saxons, drove the Saracens out of Corsica, and conquered Venice (810). He died in 810.—PEPIN, son of Louis the Pious, was made king of Aquitania, revolted twice against his father and deposed him, but finally restored him, and protected him until he himself died (838). See CARLOVINGIANS, FRANCE.

Pepper (*Piper*), a genus of Piperaceæ (q.v.),

Black Pepper (*Piper nigrum*).

which once included the whole family, but, as now limited, consists of plants with woody stems, solitary spikes opposite to the leaves, and flowers on all sides, the flowers mostly hermaphrodite. The most important species is Common or Black Pepper (*P. nigrum*), a native of the East Indies, now cultivated also in many tropical countries; its berry or drupe being the most common and largely used

leaves. The fruit is about the size of a pea, of a bright-red colour when ripe, not crowded on the spike. In cultivation the pepper plant is supported by poles, or by small trees planted for the purpose, as it loves a certain degree of shade, and different kinds of trees are often planted for this purpose in India. It is propagated by cuttings or suckers, comes into bearing in three or four years after it is planted, and yields two crops annually for about twelve years. When any of the 'berries' of a spike begin to change from green to red all are gathered, as when more fully ripe they are less pungent, besides being apt to drop off. They are spread on mats to dry in the sun, and separated from the spikes by rubbing with the hands or by treading with the feet, after which they are cleaned by winnowing. The Black Pepper of commerce consists of the berries thus dried, which become wrinkled and black; White Pepper is the seed freed from the skin and fleshy part of the fruit, to effect which the dried fruit is soaked in water and then rubbed. White pepper thus prepared is of a whitish-gray colour, but not infrequently undergoes a bleaching by chlorine, which improves its appearance at the expense of its quality. Black pepper is much more pungent than white pepper, the essential constituents of the spice being more abundant in the outer parts of the fruit than in the seed. Pepper depends for its properties chiefly on an acrid resin and volatile oil; it contains also a crystalline substance called *Piperin*. The fruits of other species of Piperaceæ are used as pepper in their native countries. That of *Piper longum* yields the Long Pepper of commerce. It has woody climbing stems, solitary spikes opposite to the leaves, diœcious flowers, and the fruits so close together on the spikes as in ripening to become a compact mass. The spikes are gathered when unripe, and dried in the sun. They are used in pickling and for culinary purposes, also in medicine for the same purposes as common pepper. They are generally reputed to be more pungent than common pepper. Benin pepper is *Piper Chusum*. *Peperomia Roseburghii* is cultivated in eastern India, Ceylon, and Java. The root and thickest part of its stem are extensively used in India as a stimulant medicine. See also BETEL, CUBES.

Pepper acts on the skin as a rubefacient and vesicant, and is often used for this purpose in a powdered state, moistened with some kind of alcoholic spirit. It is also employed as a local stimulant in relaxation of the uvula, and is applied in the form of an ointment to ringworm. Taken into the stomach in small quantities it is a pleasant stimulant, but in large doses it produces great pain and irritation. The quantity used, however, by the natives of hot climates much exceeds anything known among Europeans, and the effects are evidently beneficial rather than injurious. The chief use of pepper is as a spice and condiment.

Pepper was known to the ancients; Hippocrates employed it as a medicine, and Pliny expresses his surprise that it should have come into general use, considering its want of flavour. In the middle ages pepper was one of the most costly spices.

The name pepper is popularly given to substances possessing a pungency resembling that of pepper, although produced by very different plants. Thus, Cayenne Pepper is the produce of species of *Capiscum* (q.v.), of the family Solanaceæ; Jamaica Pepper, or Pimento (q.v.), of species of *Eugenia*, of the Myrtaceæ; Guinea Pepper (q.v.), or Maleguetta Pepper, is *Annonum*, Ethiopian Pepper *Xylopin athiopica*.

Pepper, JOHN HENRY, chemist and mechanical inventor, was born in Westminster on 17th June 1821, and in 1848 was appointed analytical chemist at the Royal Polytechnic, and wrote

several handbooks of popular science. But he is best known as the improver and exhibitor of 'Pepper's Ghost,' in its earliest form the invention of Henry Dircks (q.v.), a device for associating on the same stage living persons and phantoms to act together. The phantom is produced by a large sheet of unsilvered glass on the stage, practically invisible to the spectators, which reflects to them, along with a visible actor or actors, the appearance of another actor on an understage, himself invisible. Pepper travelled with this show in America and Australia, and became public analyst in Brisbane, Queensland. He died in 1900.

Peppercorn Rent, a nominal rent of one peppercorn a year, to be paid on demand; an acknowledgment of tenancy when lands or houses are let virtually free of rent.

Peppermint. See MINT.

Pepper-pot, a celebrated West Indian dish, of which Cusareep (q.v.) is a principal ingredient; and along with it flesh or dried fish, vegetables, chiefly the unripe pods of the ochro (a Hibiscus, q.v.), and chillies (see CAPSICUM).

Pepper-root (*Cerberine diphylla*), a perennial herbaceous plant, of the Cinerifere, a native of North America, with pairs of ternate leaves, and racemes of white flowers. The root, of pungent mustard-like taste, is used as a condiment.

Pepsin is the characteristic digestive enzyme of the gastric juice of all vertebrate animals (see DIGESTION), and a similar enzyme is found in flesh-eating plants (such as the sundew, &c.). It is only active in the presence of acid, and requires such a concentration of acid as rapidly inhibits the action of all other enzymes. Commercial pepsin is made by digesting the mucus membrane of the stomach of the pig with dilute hydrochloric acid for twenty-four hours, filtering and evaporating the clear filtrate in a vacuum at a low temperature, the residue being obtained in the form of a powder or of brown scales. It is largely used in medicine as a remedy for digestive troubles.

Peptones. See DIGESTION.

Pepys, SAMUEL, the celebrated diarist, son of John and Margaret Pepys, was born on 23d February 1632-33. He was a member of a junior branch of an old and widely-spread family in the eastern counties, but there was little property in the possession of this branch, and Samuel's father for a time followed the business of a tailor in the city of London. It was long doubted whether he was born at Brampton, near Huntingdon, where there was a small property belonging to his father's family, or in London. We know, however, that he was christened in London, that he went to school at Huntingdon before entering St Paul's School, and that he remained at the latter until he was seventeen years of age. On 5th March 1650-51 he first put on his gown as a scholar at Magdalene College, Cambridge. On the 1st December 1655, very soon after leaving college, he was married to Elizabeth St Michel, a beautiful but portionless girl of fifteen. Sir Edward Montagu (afterwards Earl of Sandwich), whose mother was a Pepys, gave a helping hand to the imprudent couple, and allowed them to live in his house. As Samuel does not appear to have owed much to his father, it seems probable that Montagu acted as a patron at a still earlier period of his life. At all events his true state was entirely due to this patron, for whom Pepys always expressed the most unbounded attachment. Pepys's real life begins for us on the 1st January 1659-60, when the *Diary* was commenced. His appointment to the clerkship of the Acts of the Navy in 1660 was distinctly a job, for he knew nothing of the work of the navy when he undertook the office, but it was a job that amply

justified itself, for his intelligence and industry were so great that he soon became master of the work of his office, and as Clerk of the Acts, and subsequently as Secretary to the Admiralty, he was one of the most distinguished officials in naval affairs that England has ever possessed. At the Revolution his career was closed, but until the end of his life he was still looked upon as the Nestor of navy affairs, to be consulted upon matters of particular importance, and his name is still held in honour at the Admiralty. It is not, however, as an official that the fame of Pepys still lives, but as the writer of a *Diary* which is unique in the literature of the world. This work has thrown the most unexpected light upon the history and manners of his day, while at the same time it presents a most remarkable psychological study. Never before had man written down his inmost feelings with so little disguise. Hence Pepys's character has suffered while his fame has spread. Passing thoughts which had but little real influence upon his actions were set down by him, and they have given a wrong impression of the man to numerous readers.

Pepys's life was prosperous, for he made money and held high offices. He was twice Master of the Trinity House, first in 1676 and a second time in 1685, Master of the Clothworkers Company in 1677, and President of the Royal Society (1684-86). But he was not without his troubles. At the period of the supposed Popish Plot in 1679 he was committed to the Tower, and in 1690 he was placed in Gatehouse at Westminster for a few days; and at his death the crown was indebted to him to the extent of £28,000, a sum which was never paid. The *Diary* ends on 31st May 1669, and we must ever regret that it was not continued to a later period. The shorthand MS. was deciphered by the Rev. J. Smith, and first published in 1825 under the editorship of Lord Braybrooke, but never in its entirety until 1893-99. Besides the *Diary*, Pepys wrote *Memoirs relating to the State of the Royal Navy*, published in 1690. Pepys was essentially a collector, and he never saw a curious or uncommon object without wishing to possess it. His library, bequeathed to Magdalene College, Cambridge, still remains in the exact condition in which he left it. In the room containing that library and among his books and papers we better understand that method, diligence, and general intelligence which is exhibited in the *Diary*, and which, united with the power of carrying out his views, helped to consolidate the British navy.

See *Memoirs of Samuel Pepys, Esq., Comprising his Diary from 1659 to 1669*, edited by Lord Braybrooke (2 vols. 1825); *Diary and Correspondence*, by Rev. Myers Bright (6 vols. 1875); *Life, Journal, and Correspondence of Samuel Pepys*, by Rev. John Smith (2 vols. 1841); *Samuel Pepys and the World he lived in* (1890) and the edition of the *Diary* (9 vols. and supplement, 1893-99), by H. R. Wheatley; and *Private Correspondence and Miscellaneous Papers of Samuel Pepys: 1679-1703*, by J. R. Tanner (2 vols. 1926), consisting almost wholly of unpublished matter; besides several works by Dr J. R. Tanner.

Pequots, or PEQUOTS, a tribe of American Indians, a branch of the Mohicans, were warlike and powerful in the country round the Thames River when Connecticut was first settled.

Pera, a suburb of Constantinople (q.v.).

Peradeniya, 3 miles out of Kandy in Ceylon, is the seat of a celebrated Botanic Garden and laboratory.

Perera (Gr. *Peraia*, 'the country beyond'), a term applied to many districts beyond a river or sea; most frequently to great part of Palestine (q.v.) beyond the Jordan. See KERAK.

Perak, one of the Federated Malay States, on the west side of the Malay Peninsula, under the pro-

tection of Britain since 1874. Estimated area, 7800 sq. m. The interior ranges up to 8000 feet. The soil is fertile, and for the most part covered with luxuriant vegetation. Elephants, leopards, huge snakes, and deer swarm in the inland forests. The soil produces rubber, rice, sugar, tobacco, coffee, tea, vanilla, and spices. But the principal production of the state is tin. Lead also exists in great quantity. Pop., mostly Malays and Chinese, increased from 55,880 in 1879 to 600,000 in 1921. The capital is Tapping, a tin-mining town. There are several railways. The British have made many miles of good roads. The state is now in a highly prosperous condition.

Perambulation. See BOUNDS (BEATING THE).

Perameles. See BANDICOOT.

Perception, in philosophical usage, may mean internal perception, the apprehension of any modification of consciousness; but it usually refers to external perception, the recognition of an external object by means of the senses—something more than sensation, and including an element of judgment or the comparing power.

Two great disputes connect themselves with perception, both raised into prominence by Berkeley. The first is the origin of our judgments of the distances and real magnitudes of visible bodies; Berkeley maintaining, in opposition to the common opinion on this subject, that these were learned by experience, and not known by the mere act of vision (see VISION). The second question relates to the grounds we have for asserting the existence of an external and material world. See BERKELEY, KANT, REID; also PSYCHOLOGY, PHILOSOPHY.

Perceval, SPENCER, English minister, was the second son of the second Earl of Egmont, and was born in London, November 1, 1762. He was educated at Harrow and Trinity College, Cambridge, and was called to the bar at Lincoln's Inn in 1786. He soon obtained a reputation as a diligent lawyer, and in 1796 he entered parliament for Northampton, and became a strong supporter of Pitt. In the Addington administration he was made Solicitor-general in 1801 and Attorney-general in 1802, and in the Portland administration of 1807 he became Chancellor of the Exchequer, and was even then the real head of the government, being much trusted by George III. for his steadfast opposition to the Catholic claims. On the death of the Duke of Portland in 1809 Perceval became premier also, and retained office till his tragic death, 11th May 1812, when he was shot dead entering the lobby of the House of Commons, about five in the afternoon, by a Liverpool broker named Bellingham, whose losses had turned his head. Perceval's death was rather a private than a public calamity. He was a man of spotless integrity in his public and private character, but, though an effective parliamentary debater, his abilities were only moderate and his views were narrow. See Treherne, *Spencer Perceval* (1909).

Perch (*Perca*), a genus of spiny-finned or acanthopteron fishes, well represented by the Fresh-water Perch (*P. fluviatilis*). The members of the large family (Percidae) to which the perch belongs are carnivorous fishes, frequenting the fresh waters and coasts of temperate and tropical regions. The body is somewhat compressed; the spinous dorsal fin is well developed; the ventral fins are thoracic in position; the teeth are simple and conical; there are no barbels. These characters are possessed by many perch-like fishes, some of which are discussed in separate articles—e.g. the Bass (*Labrax*); the Perch (*Lates*) of the Nile, Gauges, &c.; the Pike-perch (*Lucio-perca*); the Sen-perch (*Serranus*); the Murray Cod and Haploids (*Oligorus*); the Growler (*Glystes*), &c. Of American Percidae

the 'glass-eye' or 'yellow pike' (*Stizostedion vitreum*) is largest and most important, while the dwarf-perches or darters (*Microperca*, Percina, &c. are among the minutest fishes, *Microperca punctata* measuring only an inch and a half.

The fresh-water perch is widely distributed in lakes, ponds, and rivers in Europe, North Asia and North America, and is common in many parts of Britain. It is of a greenish-brown colour above and golden yellow on the under parts, with six or

Perch (*Percu fluviatilis*).

seven indistinct dark bands on the back. Its length it measures about 18 inches, and its height is about a third of this. It sometimes weighs from three to five pounds, and a prize of nine pound has been recorded. Among its characteristic may be noted the small villiform backward-turned teeth, their presence on the palatines and vomer, their absence from the tongue, the two dorsal fins of which the first has thirteen or fourteen spines and the small scales on the body. The perch loves still waters, and thrives well in ponds, at the cost, however, of smaller fishes. It also feeds on insects, worms, &c. It can endure removal from the water for a considerable time. The eggs are laid in spring, and are attached in long viscid strings to water-weeds. The number of eggs in one spawn may exceed a million. As an edible fish the perch has a good reputation, eating best with lemon-juice and cayenne-pepper, but the American variety is less esteemed. One species distinct from *P. fluviatilis* little is known. The so-called Climbing Perch (q.v.) is separately treated.

Perch. See RAD.

Percival, JAMES GATES, an American poet, was born at Kensington, Connecticut, 15th September 1795, graduated at Yale in 1815, at the head of his class, and afterwards studied botany and medicine. But his heart was not in herbs and physic, and although he practised—or rather advertised his willingness to practise—both in Kensington and in Charleston, S.C., very few professional calls dragged him from his favourite studies. His poems *Prometheus* and *Clara* appeared at Charleston in 1822. Two years later he filled for a few months the chair of Chemistry at West Point; but he found the duties heavy and irksome, and took himself to Boston, and then to New Haven. There the third part of *Clara* was published (1827). Percival afterwards divided his attention between his verses and geology, and as he grew older he gave more and more of his time to the new love, the visible results being Reports on the Geology of Connecticut (1842) and of Wisconsin (1855). These are valuable but very dry, and in delicious contrast to his poems, which flow freely and with volume, and on whose fluent, half-careless lines their author's learning is borne as easily as trees on a river in flood. His *Dream of a Day* appeared in 1843, and occasional lyrics for a long time after. He was appointed geologist of Wisconsin in 1854, and died there at Hazel Green, on

2d May 1856. His collected works were published in 1859, his *Life and Letters*, by J. H. Ward, in 1866.

Percussion, in Medicine, is the method of eliciting sounds by tapping or gently striking the surface of the body; its object being to determine by the nature of the sound the comparative density of the subjacent parts. This means of diagnosis was first employed by Aeneasbrunner in the middle of the 18th century, and it was afterwards adopted by Corvisart in the investigation of heart diseases; but its value was not fully appreciated till Laennec made the diseases of the chest his peculiar study; and since his time its application and various uses have been extended by the labours of Piorry, Skoda, Hughes Bennett, and other physicians.

Percussion is chiefly employed in the diagnosis of diseases of the lungs, heart, and abdominal organs. It may be *direct* (or, as some writers term it, *immediate*), or it may be *mediate*. In the former case, the part to be examined is struck with the ends of the first three fingers set close together on the same level, or with a small hammer tipped with india rubber; while in the latter, which is now almost universally adopted, a flat body is placed upon the chest, or other part to be examined, and is then struck by the fingers or hammer. The flat intervening body is termed a *Pleximeter* (from the Gr. *plêxis*, 'a blow,' and *metron*, 'a measure'). The instrument usually sold as a pleximeter is a flat oval piece of ivory, but the left index or middle finger of the physician, with its flat surface fitted accurately to the part to be examined, acts equally well. The force of the stroke on the pleximeter—whether the stroke be made with the fingers or the hammer—must vary according as it is desired to elicit the sound from a superficial or a deep-seated part. The surface to be percussed should be exposed, or, at most, only covered with one layer of clothing; and the blow should fall perpendicularly on the pleximeter. When percussion is made over a considerable cavity filled with air—as the stomach or intestines—a hollow, drum-like, or (as it is usually termed by medical writers) a *tympanic* sound is produced. When any part of the surface of the chest is struck below which there is a considerable depth of healthy lung-tissue, consisting of small cells filled with air, a clear sound, less loud and hollow than the tympanic sound, and termed the *pulmonary percussion note*, depending partly on the vibrations of air in the lung-cells, and partly on the vibrations of the walls of the chest, is evolved. When the subjacent substance is solid (as the heart, liver, or spleen) or fluid (as when there is effusion into a closed sac) the sound is *dull* in proportion to the density and want of elasticity of the part struck. Important information is also gained by attending to the varying degree of resistance experienced by the fingers during percussion over different parts of the surface. The first thing that must be acquired in order to make percussion useful in the diagnosis of disease is an accurate knowledge of the sounds elicited from the different parts in their normal condition. When, for example, the healthy pulmonary percussion note is known, increased resonance of the walls of the chest will indicate a dilatation of the air-cells (or Pulmonary Emphysema), while various degrees of dullness will afford evidence of such morbid changes as deposit of tuberculous material, the widespread consolidation of pneumonia, or the presence of effusion in pleurisy. This is further shown in the articles PERICARDIUM and PLEURISY. Diagnosis by Auscultation (q.v.), directly and by means of the Stethoscope (q.v.), is often used in connection with percussion, and in recent years the conditions discovered by percussion are confirmed and further elucidated by X-ray examination.

Percussion Caps are small copper cylinders, closed at one end, for conveniently holding the detonating powder which is exploded by the act of percussion in percussion-arms. See FULMINATES; also FIREARMS.

Percussion, CENTRE OF. See CENTRE OF PERCUSSION.

Percy, a noble northern family, famous in the history of England for five hundred years. Its founder, William de Percy, came with the Conqueror to England, and was rewarded with lands in Hampshire, Lincolnshire, and Yorkshire—among the last being Topcliffe and Spofforth, long the chief seats of the house. The male descendants became extinct with the death of the third baron, and the representation of the house devolved upon his daughter Agnes, who married Josceline of Louvain, brother-in-law of King Henry I., on the condition that he assumed the name of Percy. Their youngest son, Richard de Percy, then head of the family, was one of the chief barons who extorted Magna Carta from King John, and the ninth feudal lord, Henry de Percy, gave much aid to Edward I. in the subjugation of Scotland, and was made governor of Galloway. The latter was driven out of Trimberly Castle by Robert Bruce, and was rewarded by Edward II. with the empty honour of Bruce's forfeited earldom of Carnick, and the governorship of the castles of Bamborough and Scarborough. In 1309 he obtained by purchase from Bishop Antony Bek the barony of Alnwick, the chief seat of the family ever since. His son, Henry de Percy, defeated and captured King David II. of Scotland at the battle of Neville's Cross (1346); his grandson fought at Crécy; his great-grandson, the fourth Lord Percy of Alnwick, was marshal of England at the coronation of Richard II., and was created the same day Earl of Northumberland. Henry, eldest son of the last, was the famous Hotspur whom the dead Douglas defeated at Otterburn (1388), and who himself fell at Shrewsbury (1403) fighting against King Henry IV. His brother, Thomas Percy, Earl of Worcester, was executed immediately after the battle. Their father, who had turned against Richard II., and helped Henry of Lancaster to the throne, was dissatisfied with Henry's gratitude, and with his sons plotted the insurrection which ended in Shrewsbury fight. Later he joined Archbishop Scrope's plot, and fell at Bramham Moor (1408), when his honours were forfeited on attainder, but restored in 1414 to his grandson Henry, the second earl, from which day the Lancastrian loyalty of the family never wavered. Henry became High Constable of England, and fell in the first battle of St Albans (1455). His son Henry, the third earl, fell at Towton (1461), and it was his brother, Sir Ralph Percy, who comforted himself as he lay bleeding to death on Hedgley Moor (1464), that he had 'saved the bird in his bosom.' The title and estates were now given to Lord Montagu, a brother of Warwick, the king-maker, but in 1469 Henry, the son of the third earl, subscribed an oath of allegiance to Edward IV., and was restored. He was murdered at his Yorkshire house of Cocklodge, in 1489, in an outburst of popular fury against an extortionate subsidy of Henry VII. The sixth earl, Henry-Algermon, in youth had been the lover of Anne Boleyn, and was forced against his will to marry a daughter of the Earl of Shrewsbury. He died childless in 1537, and, as his brother Sir Thomas Percy had been attainted and executed for his share in the Pilgrimage of Grace, the title and honours were forfeited, and the title of Duke of Northumberland was conferred by Edward VI. upon John Dudley, Earl of Warwick, who in turn

was attainted and executed under Mary in 1553. That queen in 1557 granted the earldom to Thomas Percy, son of the attainted Sir Thomas Percy. A devoted Catholic, he took part in the Rising of the North, and was beheaded at York in 1572. His brother Henry succeeded as eighth earl. He became involved in Throgmorton's conspiracy in favour of Mary Stuart, and was committed to the Tower, where he was found dead in bed, with a pistol beside him, whether through suicide or murder, 21st June 1585. His son, the ninth earl, was imprisoned for fifteen years in the Tower, and fined £30,000 on a baseless suspicion of being privy to the Gunpowder Plot. He was followed by his son, the tenth earl, who fought on the parliamentary side in the Civil War, and was succeeded by his son Josceline, the eleventh earl, with whose death in 1670 the male line of the family became extinct. Charles II. created in 1674 his third bastard by the Duchess of Cleveland, Earl, and afterwards Duke, of Northumberland, but the titles expired on his dying childless in 1716. The eleventh earl's only surviving child and heiress, in her own right Baroness Percy, married Charles Seymour, Duke of Somerset, and became the mother of Algernon, Duke of Somerset, who was created in 1749 Baron Warkworth and Earl of Northumberland, with remainder to his son-in-law, Sir Hugh Smithson, fourth Baronet, of Stanwick in Yorkshire. Sir Hugh succeeded to the earldom in 1750, assuming the surname and arms of Percy, and was created in 1766 Earl Percy and Duke of Northumberland. The sixth duke succeeded in 1867, the seventh on his death in 1899, the eighth in 1918.

See books cited under NORTHUMBERLAND; E. B. de Fonblaque's *House of Percy* (privately printed, 2 vols. 1887); and Brenan's *House of Percy* (2 vols. 1902).

Percy, THOMAS, editor of the *Reliques*, was born a grocer's son at Bridgnorth, 13th April 1729. He was educated at the grammar-school there; in 1746 entered Christ Church, Oxford; and in 1753 was presented by his college to the sequestered vicarage of Easton Mandit, Northamptonshire, where he lived for twenty-nine years. In 1759 he married happily. Three years earlier he had received also the adjacent rectory of Wilby. His leisure soon yielded fruit in *Han Kion Chooan* (4 vols. 1761), a Chinese novel translated from the Portuguese, and *Miscellaneous Pieces relating to the Chinese* (2 vols. 1762), as well as anonymously in *Fine Pieces of Runic Poetry translated from Icelandic* (1763), prompted by the success of Macpherson, and *A New Translation of the Song of Solomon from the Hebrew* (1764). In the summer of 1764 Dr Johnson paid him a long visit at Easton Mandit. In later days they sometimes quarrelled, but continued to retain a high regard for each other. 'A man out of whose company I never go without having learned something'—so Johnson described him to Boswell. 'I am sure that he vexes me sometimes, but I am afraid it is by making me feel my own ignorance.' In the February of the following year (1765) Percy published in 3 vols. the *Reliques of Ancient English Poetry* (4th ed. 1794). He had long been engaged in collecting old ballads from every quarter, and a large folio MS. of ballads had fallen accidentally into his hands, having been found 'lying dirty on the floor under a Bureau in the Parlour' of his friend Humphrey Pitt of Shiffnal, in Shropshire, 'being used by the maids to light the fire.' This he claimed as the original of his work, but of the 176 pieces in the first edition only 45 were taken from the folio MS.; while almost all these were so touched up and tricked out in false ornament and conventional 18th-century poetic diction as often to bear but little likeness to their originals. For example, the 39 lines of the 'Child of Ell' have been puffed out to 200 in Percy's version,

nor do even all the 39 originals themselves appear. Again, the 'Heir of Lin' has swollen from 125 lines to 216, and these, moreover, polished to death. The antiquary Ritson, in his 'Observations on the Ancient English Minstrels' prefixed to his *Ancient Songs from Henry III. to the Revolution* (1790), attacked Percy with characteristic acrimony, denied the very existence of the folio MS. and denounced the work as an impudent forgery, and that the worse because by a clergyman. Percy exhibited the MS. in Pall Mall, and had his portrait painted by Sir Joshua Reynolds holding it in his hand. For over a hundred years it lay hid in Eaton Hall, jealously guarded from almost all eyes, until at length Dr Furnivall, instigated by Professor Child, succeeded in getting it printed (3 vols. 1867-68; those pieces deservedly marked by the bishop 'loose and humorous' being printed separately), with Introductions by Professor Hales and himself. The MS. was 15½ inches long by 5½ wide and about 2 inches thick, and was written in a Caroline hand.

The publication of Percy's *Reliques* was first suggested to him by Shenstone. The work was dedicated to the Countess of Northumberland, and the author was soon rewarded by being made chaplain to her husband, the first duke of the present creation, while he also succeeded in persuading himself that he was a scion of the noble house of Percy. In 1769 he became chaplain to George III., and next year he took his degree of D.D. at Cambridge, and published his translation of the *North-ern Antiquities* of the Swiss historian Paul Hemi Mallet (1730-1807). In 1771 his wife was appointed nurse to the Prince Edward, afterwards father of Queen Victoria; it was to her, before their marriage, that Percy addressed the famous ballad 'O Nancy, wilt thou go with me?' first printed in 1758, and happily set to music by an Irishman, Thomas Carter (c. 1735-1804). In 1771 Percy wrote also his pleasing ballad the 'Hermit of Warkworth.' In 1778 he was appointed to the deanery of Carlisle, in 1782 to be Bishop of Dromore, with £2000 a year. His only son died in 1783; his wife in 1806; he himself, after a few years of blindness, 30th September 1811—the only survivor of the original members of Dr Johnson's famous Literary Club. He left two daughters, and was buried in the transept which he himself had added to Dromore Cathedral.

For the literary influence of the *Reliques*, see the article BALLADS. There is a variorum edition by Schöten. See the Life by the Rev. J. Peckford prefixed to vol. i. of Furnivall, and that by Miss Gausson (1908). Many of Percy's letters are given in vol. viii. of J. B. Nichol's *Illustrations of the Literary History of the 18th Century*. Hecht edited the Shenstone Correspondence. His name was assumed by the Percy Society (34 issues, 1840-82).

Percy Anecdotes, a collection of extraordinary popularity, published in monthly parts (1820-23) by 'Sholto and Reuben Percy, Brothers of the Benedictine Monastery of Mount Bengier.' Their real names were Thomas Byerley (died 1826), first editor of the *Mirror*, and Joseph Clinton Robertson (died 1852), projector and editor of the *Mechanics' Magazine*; the work owed its name to the Percy Coffee-house in Rathbone Place. An edition was prepared by John Timbs (1868).

Perdita. See ROBINSON (MARY).

Peregrine Falcon. See FALCON.

Perekop, ISTHMUS OF, connects the peninsula of the Crimea (q.v.) with the mainland of Europe. A ship-canal through the isthmus was projected in 1888, but not constructed. Remains of ancient fortifications can be seen. In the north of the isthmus is the small town of Perekop.

Père-la-Chaise. See LACHAISE; and for the cemetery, PARIS.

Perennial, in Botany, a term employed in contradistinction to Annual (q.v.) and Biennial (q.v.), to designate plants which subsist for a number of years. Some plants, however, which are annual in cold climates are perennial in warmer; whereas annuals of temperate regions become perennials in (say) North Greenland, where the summer is too short for completion of the life-cycle. The term perennial is in general applied only to herbaceous plants, and indicates a property only of their underground parts, the stems of most dying at the end of each summer. Perennial herbaceous plants are capable, like shrubs and trees, of producing flowers and fruit time after time, in which they differ from annual and biennial plants, which are fruitful only once. Those plants which are capable of being propagated by cloves, offset bulbs, or tubers are all perennial. Thus, the potato is a perennial plant, although the crop is planted in spring and reaped in autumn, like that of corn, whilst all the corn plants are annuals. There is great diversity in the duration of life of perennial plants.

Pereaslavl, a town of Russia, 96 miles NE. of Moscow. It has a 12th-century cathedral, cotton-manufactures, and lake-fisheries. Pop. 10,000.

Pérez, ANTONIO, minister of Philip II. of Spain, was born probably at Madrid. His reputed father, an ecclesiastic, was secretary to Charles V. and Philip II., and he himself was appointed to this office in 1567. Don John of Austria having sent Escovedo to Spain to solicit aid against the party of Orange, and Escovedo having rendered himself an object of suspicion to the king as an abettor of Don John's schemes, Philip entrusted Pérez with the task of murdering him, which Pérez accordingly did, 31st March 1578. The family of Escovedo denounced Pérez, and all his enemies joined against him. The king at first sought to shield him; but in July 1579 he was arrested. Escaping to Aragon, he put himself under protection of its fueros, which secured a trial in open court. The king, charging him with heresy, now applied for aid in May 1591 to the Inquisition, and the Aragonese court delivered him up to its agents; but the people rose in tumult and liberated him from them. This happened repeatedly; and at last, in September 1591, Philip II. entered Aragon with an army powerful enough to subdue all opposition, and abolished the old constitutional privileges of the country. Pérez, however, made his escape, was condemned in Spain as a heretic, but was treated with great kindness in Paris and in London, where he was the intimate of Bacon and the Earl of Essex. He spent the later years of his life in Paris, and died there, 3d November 1611, in great poverty. Pérez wrote *Relaciones* (1594?), which some recent writers have regarded as lying fabrications.

See Mignet's monograph (5th ed. 1881); and Julia Fitzmaurice-Kelly's (1923); Morel-Fatio, *L'Espagne au XVI. et au XVII. Siècle* (1878); also Froude in *The Spanish Story of the Armada* (1892); and works cited at PHILIP II.

Pérez de Ayala, RAMON, Spanish novelist and critic, born in 1881, wrote *Novelas pormeticas, Beltramo y Apolonio*, &c.

Pérez Galdós. See GALDÓS.

Perfectibility, or **PERFECTIONISM**, the doctrine that man in a state of grace may attain to perfection in this life. Catholics hold that no one, not even the most holy, can avoid sin altogether except by a special privilege of God, as in the case of the Blessed Virgin; the justified do not, however, commit mortal, but venial sins (see SIN). In various points Franciscans, Jesuits, and Molinists approach to a doctrine of perfection denied by

Dominicans and Jansenists. Among Protestants, Wesleyan Methodists believe in the possibility of a *Christian perfection* attainable in this life. It is not a perfection of *justification*, but a perfection of *sanctification*; which John Wesley, in a sermon on Christian Perfection, from the text Heb. vi. 1, 'Let us go on to perfection,' earnestly contends for as attainable in this life by believers, by arguments founded chiefly on the commandments and promises of Scripture concerning sanctification; guarding his doctrine, however, by saying that it is neither an *angelic* nor an *Adamic* perfection, and does not exclude ignorance and error of judgment, with consequent wrong affections, such as 'needless fear or ill-grounded hope, unreasonable love, or unreasonable aversion.' He admits, also, that even in this sense it is a rare attainment. The Friends profess that the justified may be 'free from actual sinning and transgression of the law of God, and in that respect perfect. Yet doth this perfection admit of a growth; and there remaineth a possibility of sinning where the mind doth not most diligently and watchfully attend unto the Lord.' Other schools also hold similar views; but most Protestants repudiate the doctrine of Perfectibility. For another sense of the term, see ILLUMINATION.

Perfection, COUNSELS OF. See SUPEREROGATION.

Perfectionists, also called **BIBLE COMMUNISTS** and **FREE-LOVERS**, a small American sect, founded by John Humphrey Noyes, who was born at Brattleboro, Vermont, 6th September 1811, graduated at Dartmouth in 1830, then studied law, and afterwards theology at Andover and Yale. While a theological student, he experienced a second conversion, discovered that the prevailing theology was wholly wrong, and lost his license to preach. He held that the gospel if accepted secures freedom from sin; that God has a dual body (male and female); that the author of evil is uncreated, but not God; and that communion with Christ not merely saves from sinning, but from disease and death. He now founded a 'Perfectionist' church at Putney, Vermont. He and his converts, men and women, with their children, put their property into a common stock; they gave up the use of prayer, all religious service, and the observance of the Sabbath; those who were married renounced their marriage ties, and a 'complex marriage' was established between all the males and all the females of the 'Family.' Having dispensed with law, he set up public opinion as a controlling power in its stead; and free criticism of one another by the members of the society became an important feature of his system. In 1848, after not a few difficulties, the community removed to a new home in the sequestered district of Oneida, in the state of New York, and soon numbered some 300 members, living in strict order and with much outward comfort on thoroughly communistic principles—the community of women and of children being an outstanding feature carefully regulated by the 'mutual criticism' of the family. In 1880, however, the pressure of outside opinion forced the family to modify their peculiar principles; marriage and the ordinary family relationship was introduced; communism of property gave way to limited liability joint-stock, each member having a separate share represented by so much stock in the Oneida Community, Limited. Various co-operative institutions were also established. The headquarters are at Kenwood, New York, and works have been started also at Niagara Falls, Ontario. Noyes, who assisted in elaborating the new constitution, died at Niagara Falls, 13th April 1886.

See Hinds, *American Communities* (Chicago, 1902); works by Noyes, *The Second Coming of Christ and His*

tory of American Socialism; the periodicals conducted by him (nearly 40 vols. 1834-80; in British Museum); Hapworth Dixon, *New America*, &c.; Charles Nordhoff, *Communist Societies of the United States* (1875); Hillquit, *History of Socialism in the United States*; Wells, *The New Utopia*.

Perfumery. *Vegetable Perfumes.*—The most ancient of the so-called primary odoriferous bodies are the gum resins which exude naturally from trees, or from wounds accidental or purposely inflicted to increase the yield. The most important are benzoin, myrrh, opoponax, tolu, Peru, and storax. Gum resins form the chief ingredients in Incense (q.v.) and Pastilles (q.v.).

A second group is that large class of perfumes which are procured by distillation, and are mostly fluid bodies, and are termed Volatile Oils, Essential Oils, Attars, or Ottos—formerly Quintessences. As soon as the Greeks and the Romans learned the use of the still, which was an invention imported by them from Egypt, they quickly adapted it to the separation of the odorous principle from the numerous fragrant plants indigenous to Greece and Italy. Long before that time, however, fragrant waters were in use in Arabia. Odour-bearing plants contain the fragrant principle in minute glands or sacs; these are found sometimes in the rind of the fruit, as the lemon and orange; in others it is in the leaves, as sage, mint, and thyme; in wood, as rose-wood and sandalwood; in the bark, as cassia and cinnamon; in seeds, as caraway and nutmeg; in yet others in the petals, as in rose, lavender, or Ylang-Ylang. The odour principle of orris is a solid resembling cocoa-butter, and is contained in what is really the rhizome of *Iris florentina*, though technically called orris-root. These glands or bags of fragrance may be plainly seen in a thin-cut slice of orange-peel; so also in a bay leaf, if it be held up to the sunlight, the oil-cells may be seen like specks. All the fragrance-bearing substances yield by distillation an essential oil peculiar to each; thus is procured oil of patchouli from the leaves of the patchouli plant, *Pogostemon Heyneanus*, a native of Burma; oil of caraway, from the caraway-seed; oil of geranium, from the leaves of *Pelargonium roseum*; oil of lemon, from lemon-peel, and so on.

The process of Distillation (q.v.) is very simple: the fragrant part of the plant is put into the still and covered with water, and when the water is made to boil the ottos rise along with the steam, are condensed with it in the pipe, and remain floating on the water, from which they are easily separated by decanting. In this way 100 lb. of orange, lemon, or bergamot fruit peel will yield about 10 oz. of the fragrant oil; 100 lb. of cedar wood will give about 15 oz. of oil of cedar; 100 lb. of nutmeg will yield 60 to 70 oz. of oil of nutmeg; 100 lb. of geranium leaves will yield 2 oz. of oil.

The lemon-like odours are the most numerous, such as verberna, lemon, bergamot, orange, citron, citronella; then the almond-like odours, such as heliotrope, vanilla, violet; then spice odours, cloves, cinnamon, cassia. The whole may be classified into twelve well-defined groups. All these ottos are very soluble in alcohol, in fat, butter, and fixed oils. They also mix with soap, snuff, starch, sugar, chalk, and other bodies, to which they impart their fragrance.

Some flowers yield little or no essential oil by distillation. The perfume from these is collected by *enfleurage*. The flower-farmers of the Alpes Maritimes follow this method on a very large scale with rose, orange, acacia, violet, jasmine, tuberose, and jonquil. The blossoms, spread upon layers of fat, are changed every day, or every other day. The grease remains. Each time the fresh flowers are put on it is 'worked' with a knife, so as to

offer a fresh surface. The grease being *enfleuré* or 'inflored' in this way for three weeks or more—in fact, so long as the plants produce blossoms, or the fat is capable of absorbing more odour—is at last scraped off the *châsse*, melted, strained, and poured. Fat or oil is also perfumed with these same flowers by the process of *maceration*—i.e. infusion of the flowers in oil or melted fat. After some hours the spent blossoms are strained away, and new added repeatedly, so long as they can be procured. Improved results are obtained by slightly heating the oil.

Jasmine and tuberose produce best perfumed grease by *enfleurage*; rose, orange, and acacia by *maceration*; while violet and jonquil grease is best obtained by *enfleurage* followed by *maceration*.

To extract the odour from solid fat it is chopped up fine, put into strong alcohol, and left to infuse for about a month. Scented oil has to be repeatedly agitated with the spirit. The spirit extracts all the odour, becoming itself 'perfume,' while the grease again becomes odourless. The reason for producing a pomade—as these scented fats are technically termed—of orange-flowers is that the odour of the essential oil obtained by the distillation of orange-blossoms with water has not, in the least degree, the odour of the orange-blossoms from which it is obtained. The otto in fact undergoes a chemical change, and becomes Neroli. The same applies, in a less marked degree, to rose.

Perfumes of Animal Origin.—Only four of these are used in perfumery—viz. Musk (q.v.), Ambrois (q.v.), Civet (q.v.), and Castor (see CASTOREUM). The power of musk to impart odour is such that polished steel will become fragrant if it be shut in a box where there is musk, contact not being necessary. In perfumery manufacture tincture of musk is mixed with other odorous bodies to give permanence to the more evanescent perfumes or bouquets, the musk acting to them almost as a mordant does to a dyestuff.

Civet is exceedingly potent as an odour, and when pure, and smelled at in the bulk of an ounce or so, is utterly insupportable from its nauseousness; in this respect it exceeds musk. But when it is much diluted its sweet perfume is generally admitted; the fragrant principle is the same as that of the narcissus. Civet is extensively used daily attenuated in perfumery. Its powerful and lasting odour enables it to be used in some soaps, and especially in sachets. It is one of the perfumes of 'Spanish Leather,' or *Peau d'Espagne*: the first gloves used in England were scented with it.

Castor cannot be largely used in any given perfume on account of the almost blackness of its tincture, still when properly diluted it is extensively employed. Its perfume, when old especially, is exceedingly pleasant, and its *fœt*ing power is at least equal to that of musk.

Synthetic Perfumes.—The progress of scientific chemistry has led to the production of numerous odoriferous substances, some identical with the active odoriferous principles of plants. Among them may be mentioned vanillin, the principle of vanilla (methyl protocatechic aldehyde); coumarin, of Tonquin bark (coumaric anhydride); ionone, of violet; and many derivatives of phenol. The artificial musk of L. Bauer is a delightful perfume, and has many applications in perfumery; but it differs widely in odour from true musk.

The perfumes or bouquets of the shops are really mixtures of some or several of the primitive odours. An example or two will illustrate this. 'Jockey Club Bouquet' is thus compounded: 2 gal. extract of orris; $\frac{1}{2}$ gal. each of cassia, rose, and tuberose pomades; $\frac{1}{2}$ gal. civet; $\frac{1}{2}$ gal. musk; $\frac{1}{2}$ gal. spirits of wine; 8 oz. bergamot otto; 14 oz. rose. 'White Rose': 2 pints extract rose pomade; 1 pint each

cassia and jasmine: $1\frac{1}{2}$ pint spirits of wine; $\frac{1}{2}$ oz. rose otto; 1 drm. patchouli otto. It is obvious that the possible variety is infinite.

See OTTO OF ROSES, Musk, &c.; and works by E. J. Parry.

Pergamus, or **PERGAMUM**, anciently a city of Mysia in Asia Minor, on the river Caicus, 15 miles from its mouth. According to tradition, the place was founded by Greeks from Arcadia. It first acquired prominence when Lysimachus, one of Alexander's generals, chose it as a stronghold to keep his treasures in. Under Phileterus, his eunuch, whom he appointed guardian of his treasures, it became the capital of a state; 283 B.C. His successor, Eumenes I., maintained its independence against the Seleucids, although the title of king was first assumed by Attalus I., who reigned from 241 to 197 B.C., and defeated the Gauls in a great battle. He intimately allied himself with the Romans against Philip V. of Macedon, and this alliance subsisted throughout succeeding reigns, during which the kingdom continued to increase in extent and importance. Attalus III., surnamed Philometer, who died in 133 B.C., left it to the Romans, and under them it was one of the chief cities of Asia Minor. The native kings had adorned it with grand sculptures, the work of artists belonging to the Pergamenean school, and collected a library only inferior to that of Alexandria. Pergamus was a special seat of the worship of Asclepius (Æsculapins); and it gave its name to Puchment (q.v.). It began to decline under the Byzantine emperors. The place still exists under the name *Bergama*, and is noted for the splendour and magnificence of its ruins, which embrace temples, palaces, aqueducts, gymnasia, amphitheatres, and city walls. These were excavated for the Prussian government by Humann, Bohn, and others, in 1878-86, many of the treasures being carried to Berlin.

Pergolese, GIOVANNI BATTISTA, Italian musician, was born at Jesi, near Ancona, on 3d January 1710, studied music at Naples, and struck out an original style for himself. His first great work was the oratorio of *San Gaglianò*, composed in 1731, soon followed by his bright and tuneful operetta of *La Serra Padrona*. This is his masterpiece. In 1734 he was appointed *maestro di capella* of the Church of Loreto. In consequence of delicate health he removed to Pozzuoli, where he composed the cantata of *Orfeo* and his second masterpiece, the pathetic *Stabat Mater*, but died immediately afterwards on 16th March 1736. Besides the works named, Pergolese composed numerous operas, oratorios, and other pieces.

Peri, according to the mythical lore of the East, a being begotten by fallen spirits, which spends its life in all imaginable delights, is immortal, but is for ever excluded from the joys of Paradise. It takes an intermediate place between angels and demons, and is either male or female. So far from there being only female Peris, as is supposed by some, and these the wives of the Devs, the Peris live, on the contrary, in constant warfare with these Devs. Otherwise, they are of the most innocuous character to mankind, and, just like the fairies with whom our own popular mythology has made us familiar, are when female of surpassing beauty. They belong to the great family of genii, or Jinn (see DEMONOLOGY).

Periagua, a large canoe composed of the trunks of two trees, hollowed and united into one fabric; whereas an ordinary canoe is formed of the body of one tree only.

Perianth. See FLOWER.

Pericardium, a conical membranous sac containing the heart and the commencement of the

great vessels, to the extent of about 2 inches upwards behind the sternum in the interval between the pleura—the serous sacs in which the lungs are enclosed; while its base is attached to the diaphragm. It is a fibro-serous membrane, consisting of an external fibrous and an internal serous layer. The outer layer is a strong, dense, fibrous membrane; the serous layer invests the heart, and is then reflected on the inner surface of the fibrous layer. Like all serous membranes, it is a closed sac; its inner surface is smooth and glistening, and secretes a thin fluid which serves to facilitate the natural movements of the heart. Inflammation of this serous sac constitutes the disease known as pericarditis.

DISEASES OF THE PERICARDIUM.—Pericarditis is a disease of frequent occurrence; the result of a very large number of post-mortem examinations being to show that about one in twenty-three of all who die at an adult age exhibits traces of recent or old attacks of this disorder. The first change which takes place in an inflamed pericardium is a dulling of its glistening surface, with some congestion, which is speedily followed by effusion into the sac. The effusion is sometimes almost entirely fibrinous, in which case it organises, and gives rise to adhesions between the heart and the pericardium; or it may consist almost entirely of liquid serum, which is later absorbed; or it may be, and most frequently is, a mixture of the two. In a few cases it rapidly becomes purulent. In the cases that prove fatal when fibrinous fluid has been effused, but has not organised to such an extent as to cause complete adhesion of the heart to the pericardium, the fibrin or lymph is seen to be of a yellowish-white colour, and to occur in a ragged, shaggy, or cellular form mingled with clear fluid. Laennec compared the surface on which the lymph is deposited to that which would be produced by suddenly separating two flat pieces of wood between which a thin layer of butter had been compressed. When the patient dies at a more advanced stage of the disease—viz. soon after the whole of the membrane has become adherent—incipient blood-vessels, in the form of red points and branching lines, are seen, indicating that organisation is commencing in the deposit, which if death had not ensued would have been finally converted into fibrous or cellular tissue, and might have occasioned the complete obliteration of the pericardial cavity.

The recognition of the disease depends almost entirely upon the signs revealed by auscultation and percussion. The earliest is generally the *friction-sound*, or *to and fro murmur*, caused by rubbing together of the roughened surfaces, and heard to accompany the heart's action; but if fluid is effused it may speedily disappear. In this case percussion of the chest shows that the dull area occupied by the heart is larger than normal, while the impulse of the organ on the chest-wall cannot be felt. The symptoms, besides those common to all inflammations, are extremely variable: in some cases where pericarditis comes on in the course of other serious disease the patient makes no complaint, and the complication is only discovered during the routine examination of the chest. But there may be intense pain and tenderness on pressure in the region of the heart, great irregularity or feebleness of the heart's action, distressing breathlessness, delirium, &c.

Pericarditis is a disease which occasionally runs a very rapid course, and terminates fatally in forty-eight hours or less. In ordinary cases, however, which terminate in apparent recovery, the disease generally begins to yield in a week or ten days, and, excepting that adhesion may remain, the cure appears to be complete in three weeks or less. If

the adhesions which have formed are dense and fibrous, they may impede the heart's action and lead to enlargement of the heart with serious symptoms at some subsequent period.

Pericarditis rarely occurs as an independent disease. It may result from extension of an inflammation in a neighbouring organ, pleura, ribs, &c. It is no uncommon result of an infectious disease, especially scarlattina, and of diseases associated with general degenerative changes, such as Bright's disease of the kidney; but, beyond all comparison, it is of most frequent occurrence in association with acute Rheumatism (q.v.), of which it forms one of the most serious complications. It is often associated with inflammation of the muscular substance of the heart, and, especially in rheumatism, of the lining membrane as well.

The treatment of pericarditis at present in favour is much less active than when bleeding, mercurialisation, &c., were considered necessary. Complete rest in bed, light diet, with opium or other sedatives as required; general medication suited to the disease with which the pericarditis is associated; local application of poultices or ice-bags, sometimes of iodine or blisters, are the chief measures employed. In cases where there is extensive fluid effusion it may be necessary to aspirate in order to free the heart from embarrassment.

The pericardium may also be distended with fluid without inflammation (hydropericardium) in the course of general dropsy; and occasionally is the seat of tumours, syphilitic or tubercular processes, &c.

Pericarp. See FRUIT.

Pericles, the greatest statesman of ancient Greece, was born of distinguished parentage in the early part of the 5th century B.C. His father was that Xanthippus who won the victory over the Persians at Mycale, 479 B.C.; and by his mother, Agariste, the niece of the great Athenian reformer Cleisthenes, he was connected with the princely line of Sicyon and the great house of the Alenconida. He received an elaborate education; but of all his teachers the one whom he most revered was the serene and humane philosopher Anaxagoras. Pericles was conspicuous all through his career for the singular dignity of his manners, the Olympian grandeur of his eloquence, his 'majestic intelligence,' in Plato's phrase, his sagacity, probity, and profound Athenian patriotism. Both in voice and in appearance he was so like Pisistratus that for some time he was afraid to come forward in political life. When he entered on public life Aristides had only recently died, Themistocles was an exile, and Cimon was fighting the battles of his country abroad. Although the family to which he belonged was good, it did not rank among the first in either wealth or influence, yet so transcendent were the abilities of Pericles that he rapidly rose to the highest power in the state as the leader of the dominant democracy. The sincerity of his attachment to the popular party has been questioned, but without a shadow of evidence. At any rate the measures which either personally or through his adherents he brought forward and caused to be passed were always in favour of extending the privileges of the poorer class of the citizens, and, if he diminished the spirit of reverence for the ancient institutions of public life, he enlisted an immense body of citizens on the side of law. He extended enormously, if he did not originate, the practice of distributing gratuities among the citizens for military service, for acting as diest and in the Ecclesia, and the like, as well as for admission to the theatre—then really a great school for manners and instruction. Pericles seems to have

grasped very clearly, and to have held as firmly, the modern radical idea, that, as the state is supported by the taxation of the body of the citizens, it must govern with a view to general interests rather than to those of a caste alone.

About 463 Pericles, through the agency of his follower, Ephialtes, struck a great blow at the influence of the oligarchy, by causing the decree to be passed which deprived the Areopagus of its most important political powers. Shortly after the democracy obtained another triumph in the ostracism of Cimon (461). During the next few years the political course pursued by Pericles is less clearly intelligible to us, but it is safe to say that in general his attitude was hostile to the desire for foreign conquest or territorial aggrandisement, so prevalent among his ambitious fellow-citizens. Shortly after the battle of Tanagra (457), in which he showed conspicuous courage, Pericles magnanimously carried the measure for the recall of Cimon. His successful expeditions to the Thracian Chersonese, and to Sinope on the Black Sea, together with his colonies planted at Naxos, Andros, Orens in Euboea, Brea in Macedonia, and Egina, as well as at Thurii in Italy and Amphipolis on the Strymon, did much to extend and confirm the naval supremacy of Athens, and afford a means of subsistence for her poorer citizens. But his greatest project was to form in concert with the other Hellenic states a grand Hellenic confederation in order to put an end to the mutually destructive wars of kindred peoples, and to make of Greece one mighty nation, fit to front the outlying world. The idea was not less sagacious than it was grand. Had it been accomplished the semi-barbarous Macedonians would have menaced the civilised Greeks in vain, and even Rome at a later period might perhaps have found the Adriatic, and not the Euphrates, the limit of her empire. But the Spartan aristocrats were utterly incapable of appreciating such exalted patriotism, or of understanding the political necessity for it, and by their secret intrigues the well-planned scheme was brought to nothing. Athens and Sparta were already in that mood towards each other which rendered the disaster of the Peloponnesian war inevitable. When the Spartans in 448 restored to the Delphians the guardianship of the temple and treasures of Delphi, of which they had been deprived by the Phocians, the Athenians immediately after marched an army thither, and reinstated the latter. Three years later an insurrection broke out in the tributary Megara and Euboea, and the Spartans again appeared in the field as the allies of the insurgents. The position of Athens was critical. Pericles wisely declined to fight against all his enemies at once. A bribe of ten talents sent the Spartans home, and the insurgents were then thoroughly subdued. The thirty years' peace with Sparta (445) left him free to carry out his schemes for the internal prosperity of Athens.

Cimon was now dead and was succeeded in the leadership of the aristocratical party by Thucydides, son of Melesias, who in 444 B.C. made a strong effort to overthrow the supremacy of Pericles by attacking him in the popular assembly for squandering the public money on buildings and in festivals and amusements. Thucydides made an effective speech; but Pericles immediately rose and offered to execute the buildings at his own expense, if the citizens would allow him to put his own name upon them instead of theirs. The scheme was successful, Thucydides was ostracised, and to the end of his life Pericles reigned the undisputed master of the public policy of Athens. During the rest of his career 'there was,' says the historian Thucydides, 'in name a democracy, but in reality a government in the hands of the first

man.' And the Athens of his day was the home of Æschylus, Sophocles, Euripides, Anaxagoras, Zeno, Protagoras, Socrates, as well as Myron and Phidias; while there flourished at the same time, but elsewhere in Greece, Herodotus, Hippocrates, Pindar, Empedocles, and Democritus. The centre of this splendid group was Pericles, of whom the truthful pen of Thucydides records that he never did anything unworthy of his high position, that he did not flatter the people or oppress his adversaries, and that with all his unlimited command of the public purse he was personally incorruptible.

Soon after this the Samian war broke out, in which Pericles gained high renown as a naval commander. This war originated in a quarrel between Miletus and the island of Samos, in which Athens was led to take part with the former. The Samians after an obstinate struggle were beaten, and a peace was concluded (439). The position in which Athens then stood towards many of the Greek states was peculiar. Since the time of the Persian invasion she had been the leader of the confederacy formed to resist the attacks of the powerful enemy, and the guardian of the confederate treasury kept in the isle of Delos. Pericles caused the treasury to be removed to Athens, and, committing the contingents of the allies for money, enormously increased the contributions to the patriotic fund, Athens herself undertaking to protect the confederacy. The grand charge against Pericles is that he applied the money thus obtained to other purposes than those for which it was designed; that, in short, he adorned and enriched Athens with the spoils of the allied states. To his mind Hellas was subordinate to Athens, and he confounded the splendour of the dominant city with the splendour of Greece in a manner possible to a man of poetic imagination, hardly to a man of the finest honour. His enemies, who dared not attack himself, struck at him in the persons of his friends. Phidias was flung into prison for the impiety of introducing portraits of himself and Pericles into the battle of the Amazons depicted on the shield of the goddess Athena in the Parthenon; the brilliant Aspasia (q.v.), the famous mistress of Pericles, was arraigned on a charge of impiety, and only acquitted through the eloquence of Pericles on her behalf; while the aged Anaxagoras was driven from the city.

It is unnecessary to give a detailed account of all that Pericles did to make his native city the most glorious in the ancient world. Greek architecture and sculpture under his patronage reached perfection. To him Athens owed the Parthenon, the Erechtheum, left unfinished at his death, the Propylæa, the Odæum, and numberless other public and sacred edifices; he also liberally encouraged music and the drama; and during his rule industry and commerce were in so flourishing a condition that prosperity was universal in Attica.

At length in 431 the long-foreseen and inevitable Peloponnesian war broke out between Athens and Sparta. The plan of Pericles was for Athens to follow a defensive attitude, to defend the city itself, leaving Attica to be ravaged by the enemy, but to cripple the power of Sparta by harassing its coasts. The story of the war is told elsewhere; here it is enough to say that the result was fatal to Athens for reasons for which Pericles was only in small part to blame. He trusted in the ultimate success of Athens both from her superior wealth and from her possessing the command of the sea, but he had not calculated upon the deterioration in her citizens' spirit, nor upon the boldest courage of the Boeotian and Spartan infantry. Nor was his advice to keep behind the city walls rather than face the enemy in the field best calculated to arouse the Athenians' courage. The plague ravaged the city in 430, and in the autumn of the following year

Pericles himself died after a lingering fever. His two sons had been carried off by the plague; he had been harassed by a charge of peculation brought by Cleon, and the actual infliction of a fine by the dicastery, while he had been without office from July 430 to July 429; but before the last he recovered his hold over the Ecclesia, and was gratified in the closing days of his life by its legitimization of his son by Aspasia.

His greatest fault as a statesman was a failure to foresee that personal government is ultimately ruinous to a nation. He taught the people to follow a leader, but he could not perpetuate a descent of leaders like himself. Hence we cannot wonder, when days of trouble broke over Athens, how that men spoke bitterly of Pericles and all his glory. Yet he was a lofty-minded statesman, inspired by noble aspirations, and his heart was full of a noble love for the city and her citizens. Plutarch tells the story that as he lay dying and apparently unconscious his friends around his bed were passing in review the great achievements of his life, and the nine trophies which he had erected at different times for so many victories. The dying patriot quietly interrupted with the characteristic sentence—'What you praise in my life belongs partly to good fortune, and is, at best, common to me with many generals. But that of which I am proudest you have left unnoticed—no Athenian has ever put on mourning through any act of mine.'

For his life and character, see Thucydides and Plutarch; the histories of Greece; and the excellent study by Evelyn Abbott (1891).

Peridot, Peridote. See CHRYSOLITE.

Peridotite. See IGNEOUS ROCKS.

Périer, CASIMIR, French politician, was born at Grenoble, 21st October 1777. A Parisian banker, he condemned in 1817 the financial policy of the ministry, and thereby won a seat in the Chamber of Deputies. In 1828 he held the portfolio of finance under Martignac, but resigned it in August of the next year. Having taken an active part in the July revolution (1830), he was rewarded with a seat in the cabinet, but without a portfolio. When, however, Lafitte became President of the Council (November 2), Périer undertook the presidency of the Chamber of Deputies. On 13th March 1831 he succeeded Lafitte as minister; he sternly repressed all attempts at revolution, and governed by the *Juste Milieu* (q.v.) policy. He died of cholera, 16th May 1832. For his son, see CASIMIR-PÉRIER.

Perigee. See MOON.

Périgueux, a town of France, formerly capital of Périgord, now in the department of Dordogne, and situated on the right bank of the Isle, a tributary of the Dordogne, 95 miles by rail N.E. of Bordeaux. It consists of the ancient city, which is gloomy in aspect and has narrow streets, with numerous houses and other remains of mediæval and Renaissance architecture, and the Pny St Front, which until 1269 was a separate and a rival town. The cathedral of St Front is a Byzantine edifice, said to be a copy of St Mark's at Venice, built in 984-1047, but spoilt by 'restoration' in 1865. The town museum is especially rich in Roman and other antiquities. Statues of Montaigne, Fénelon, and the soldiers Dammesnil and Bugeaud adorn public places in the town. Iron is mined and worked, and woollens are manufactured. The celebrated *pâtés de Périgueux*, made of partridges and truffles, are largely exported. Population, 33,500. Périgueux, a town of the highest antiquity, is the Gallic *Vesunna* mentioned by Cæsar. The Romans built another town on the opposite side of the river at the junction of five Roman roads. Close to the modern town are the remains of a vast amphitheatre, aqueducts, baths,

and temples. The tower of Vesunna is the most remarkable fragment of Roman architecture. It is 89 feet high, 200 feet in circumference, and has walls 6 feet thick, but has neither doors nor windows. Its purpose is not known. The district of Périgord is noted for its Caves (q.v.) and archaeological finds. See FLINT IMPLEMENTS.

Perihelion (Gr. *peri*, and *hēlios*, 'the sun'), that point in its orbit at which a planet is nearest the sun. See PLANETS, ORBIT, APHELION.

Perim, a barren island, and coaling and telegraph station, belonging to Britain, situated in the Strait of Babel Mandeb, at the southern entrance to the Red Sea, 97 miles W. of Aden, 1½ from the Arabian shore, and 9 from the African. It is about 3½ miles long by 2½ wide, having an area of 5 sq. m. It is crescent shaped, the two horns embracing a deep and spacious harbour. The island was held by the British in 1799-1800, and was again occupied in 1857. In 1883 it was made a coaling station. The island is under the jurisdiction of the governor of Bombay Presidency. Pop. about 2000.

Perineum, the floor of the human pelvis. The anterior portion, situated in front of the anus, is called the *true perineum*, or urethral portion of the perineum; the posterior portion is called the anal portion or ischio rectal region.

Period and Periodicity. One of the most striking features of the ordinary phenomena of nature is their tendency to recur and repeat themselves apparently indefinitely; and in general this repetition takes place at successive and practically equal intervals of time. The day, the month, the year are familiar examples of such periods, corresponding respectively to the earth's rotation, the moon's progression through its phases, and the earth's changes of distance from the sun. As a factor in human life the year is practically traced out by the climatic changes that accompany its progress, but strictly speaking it is the period determined by the recurring configurations of earth and sun. Many periodic phenomena of importance, such as eclipses, transits, occultations, depend like the moon's phases on the configurations of these bodies; and long before Newton's law of gravitation gave the key to the cosmic universe the periods of some of these had been discovered. See CHRONOLOGY (with its various cycles—the metonic of 19 years, the Chippie of 76 years, &c.), CYCLE, DAY, ECLIPSE, YEAR, &c.

When we look into the minute mechanism of nature we find here also the same prominence attached to periodic qualities. Sound and light consist physically of a vibratory or oscillatory motion of some sort; and to the accurate time periodicity of these motions we trace our sensations of harmony in music and colour. In certain respects, however, the periodicity is imperfect, each period not being an exact reproduction of its predecessor. Thus, a tuning fork or pianoforte-string vibrating freely in air rapidly loses its vibratory character, and its motion steadily decays; and yet, judged by the pitch, the frequency or time periodicity remains the same throughout. In these and similar cases Viscosity (q.v.) ultimately transforms the original vibratory energy into heat (see ENERGY). Heat itself is believed to be some kind of vibratory energy of the molecules; and the spectroscopic demonstrates that intense heat is certainly associated with definite periodic motions, giving rise to rays of corresponding periodicity (see SPECTRUM).

Passing now to the other extreme, we find, chiefly in astronomy, instances of long periods, some of which have not been completed within historic times, but of which the evidence is incon-

vertible. The Precession (q.v.) of the equinoxes and the slow changes in the eccentricities and inclinations of planetary orbits may be mentioned by way of illustration. The geologist also has found evidence of periodic changes in the climatic conditions of the earth (see GLACIAL PERIOD, PLEISTOCENE). Generally periodicity involves the idea of time; but we may have periodic qualities depending on position or on grouping. A very good example of this is the periodic law of modern chemistry (see ATOMIC THEORY; also WAVE).

Life is as full of periodic phenomena as inanimate nature; but the increasing complexity of conditions makes the periodicity still less perfect. In the beating of the heart, in the alternation of waking and sleeping, of hunger and satiety we have examples of vital actions with a distinct periodic character.

Periodicals. A periodical is a publication issued at regular intervals, but the term does not include newspapers. The periodical dates back to the 17th century, but for practical purposes we can begin with the *Tatler*, started in 1709. It was followed by *The Spectator*, 1711. *The Gentleman's Magazine*, issued in 1731, first established the British type of magazine. Coming to more recent times, *Blackwood's Edinburgh Magazine* was started in 1817. The popular necessity for cheap literature led to the issue in the early part of the 19th century of numerous publications of a more or less educational character, such as the *Mechanic's Magazine*, *Chambers's Journal*, and the *Penny Magazine*. These were followed by *Cassell's Popular Educator* and other periodicals of a similar type. In 1881 the periodical world was revolutionised by the appearance of *Tit-Bits*, designed and edited by the late Sir George Newnes, Bart. The chief features of this publication were the pith, brevity, and human interest of its paragraphs, and the introduction of new features such as 'Answers to Correspondents.' *Tit-Bits* was followed in 1888 by *Answers*, established by Lord Northcliffe (then Mr Harmsworth), and in 1890 by *Pearson's Weekly*, established by the late Sir Arthur Pearson, Bart. (then Mr Pearson). These publications owed their success in no small degree to competitions in which large money prizes were offered. As time has passed these competitions have become increasingly popular. They now form an outstanding feature of periodical journalism, and have been adopted by periodicals and newspapers in all parts of the world. To Sir George Newnes belongs the credit of being the founder of this type of circulation rouser. Fiction periodicals have long held a leading position in the periodical world. *The Family Herald* (1843) and the *London Journal* (1845) had large sales at a time when big circulations were few and far between. Charles Dickens established *All the Year Round* in 1850, and in this periodical appeared many of his stories in serial form. The *Cornhill* was started about 1860 under Thackeray's editorship. It marked a new epoch in high-class periodical literature. In 1891 Sir George Newnes published the first modern illustrated magazine, *The Strand*, which has been copied in all parts of the world. For years past much of the best fiction has first appeared in serial form in various magazines. This has led to developments greatly to the advantage of authors. Nowadays copyright is split into different sections—first, and second, serial rights, and book rights of different dimensions according to the price of the various editions. Vast numbers of periodicals are issued week by week by the great publishing houses. In Britain the chief are the Amalgamated Press, Ltd., established by Lords Northcliffe and Rothermere, and now managed by Sir George Sutton, Bart.;

George Newnes, Ltd., and C. Arthur Pearson, Ltd., which are associated under the chairmanship of Lord Riddell; Cassells, Ltd., controlled by the Messrs Berry and the Odhams Press, Ltd.

The high-class reviews, such as the *Edinburgh* (1802), the *Quarterly* (1800), the *Nineteenth Century* and *After* (1877), the *Contemporary* (1866), the *Fortnightly* (1867), are devoted to critical comment on public events and literature. Their sales are not large but they are influential, and these publications are much quoted in the press.

In the space available it is impossible to describe the variety of the periodicals. In Britain the number is estimated at over 3000, while America claims nearly 5000. The total number in the world is estimated at 13,000, but little reliance can be placed on this figure. Every interest in life is catered for by some periodical or periodicals—from dancing to midwifery—and perhaps, needless to say, the advertisement pages are one of the chief features and sources of profit of most periodicals. Although some French and German periodicals are conducted with much enterprise and have large sales, Britain and America are the real homes of this class of publication. In this country periodicals of the *Tid-Bits* type, the cheap novelette, and cheap papers for women have enormous sales. In America conditions are somewhat different. The Sunday newspaper provides much of the material furnished by periodicals in Britain. But, having regard to geographical necessities, the newspapers circulate only in limited areas. No newspaper has a national sale. On the other hand, publications like the *Ladies' Home Journal* and *Saturday Evening Post* circulate throughout the length and breadth of America with wonderful commercial and advertising results. The periodical press of Britain is gathered together in the Periodical Trade Press and Weekly Newspaper Proprietors' Association, Ltd.

Periophtalmus, a remarkable genus of acanthopterous fishes, allied to the gobies. Their eyes protrude and are very mobile; their pectoral fins can be used as legs. Several species occur on the coasts of the Indian Ocean and Western Africa; of these the best known is *P. koelreuteri*.

Periophtalmus koelreuteri.

(From Hickson's *Naturalist in North Celebes*, 1890.)

This fish lives about low tide-mark on the muddy flats or among rocks, and by means of its pectoral fins and tail hops along in search of crustaceans, insects, and gastropods. Respiration seems to be effected through the skin of the tail even more than by the gills. They cling by their fins to rocks and mangrove-roots, and keep their tails in the water; or they climb entirely out of the water, and jump with agility when disturbed.

Periostitis, inflammation of the periosteum, the tough fibrous membrane which surrounds

the various bones (see BONE). It generally occurs on the surface of thinly-covered bones, such as the tibia, clavicles, and cranial bones. Its chief causes are, in the acute form, an infective process following a bruise or other injury; and, in the chronic form, tuberculosis, syphilis, or rheumatism. In the acute form there are pain, tenderness to touch, redness of the skin, and swelling. In the chronic form the membrane is thickened and new bone is formed, with aching pain, usually worse at night. The treatment is by rest, elevation of the limb, and soothing applications; with, in the chronic form, internal administration of iodide of potassium.

Peripatetic Philosophy, a designation of the philosophy of Aristotle (q.v.) and of his followers. It is of doubtful origin, being supposed to have been derived either from his custom of occasionally walking about (*peripatetein*) during the delivery of his lectures, or from the place in which they were delivered being a shaded walk.

Peripatus, a genus in the class Onychophora or Prototracheata which occupies a position between myriopods and insects on the one hand and annelids on the other. Thus, along with the trachee or air-tubes characteristic of insects, *Peripatus* has the nephridia or excretory tubes characteristic of the higher worms. The body measures about two inches in length, is shaped like that of a worm or caterpillar, but without external rings, bears numerous (14 to 42) imperfectly-jointed stump-like clawed feet, and has a soft skin, with little of that chitin which is abundant as a cuticular product in other arthropods. The head bears a pair of mobile antennae, a pair of mandibles in the mouth, and a pair of oral papillae from which slime oozes. With this *Peripatus* catches its prey of small insects, &c. The species live in moist places under stones and bark, and are nocturnal in their habits. Professor Sedgwick says that 'the exquisite sensitiveness and constantly changing form of the antennae, the well-rounded plump body, the eyes set like small diamonds on the side of the head, the delicate feet, and, above all, the rich colouring and velvety texture of the skin all combine to give these animals an aspect of quite exceptional beauty.' There are many remarkable structural features: thus, the ventral nerves are widely separate; the eyes are simple, like those of an annelid; the body cavity is divided into three longitudinal compartments, from which the cavities of the legs are furthermore distinct. The sexes are separate. The development varies considerably in different species, for the ova contain a considerable amount of yolk or none at all. In several it has been observed that the cells of the embryo are for a prolonged period indistinctly separate from one another. The Onychophora are viviparous, and the newly-born young are quite like the parents except in size. The distribution is very wide; in South Africa there are several species—e.g. *P. capensis*, *P. balfouri*; in New Zealand, *P. nova Zealandiae*; in Queensland, *P. leuckartii*; in Caracás, *P. edwardsi*; in Jamaica there are two species; and there are others from Demerara, Trinidad, St Vincent, Chile, Quito, the Malay Peninsula, &c. It is usual to distinguish several other genera besides *Peripatus*, such as *Eoperipatus*, *Paraperipatus*, *Peripatoides*, *Peripatopsis*. See figure under CATERPILLAR, and Bouvier's monograph (1907).

Periscope (Gr. *peri*, 'around,' *skopein*, 'to look'), an instrument used in submarine navigation and in trench warfare for observing the surroundings at or above the surface. It consists essentially of a tube with two mirrors; one at the top, at an angle of 45° with the axis (or whatever

other angle may be required for objects overhead), reflects rays down the tube to the second, also at 45°, which reflects them horizontally to the eye. The required magnification is got by lenses.

Perissodactyla. See ARTIODACTYLA.

Peristaltic Motion, the action of the muscular coat of the intestines, by which the substances contained within it are regularly moved onward. See DIGESTION.

Peritoneum (Gr. *peritēinein*, 'to extend around'), a serous membrane, and, like all membranes of this class, a shut sac, which, however, in the female is not completely closed, as the Fallopian tubes communicate with it by their free extremities. The peritoneum more or less completely invests all the viscera lying in the abdominal and pelvic cavities, and is then reflected upon the walls of the abdomen, so that there is a visceral and a parietal layer. Numerous folds are formed by the visceral layer as it passes from one organ to another. They serve to hold the parts in position, and at the same time enclose vessels and nerves. Some of these folds are termed *Ligaments*, from their serving to support the organs. Thus, we have ligaments of the liver, spleen, bladder, and uterus formed by peritoneal folds. Others are termed *Mesenteries* (from the Gr. *meson*, 'the middle,' and *enteron*, 'the intestine'), and connect the intestines with the vertebral column. They are the Mesentery proper, the ascending, transverse, and descending meso-colon, and the meso-rectum. Lastly, there are folds called *Omenta*, which proceed from one viscus to another. The great omentum always contains some adipose tissue, which in persons inclined to corpulence often accumulates to an enormous extent. Its use appears to be (1) to protect the intestines from cold by covering them anteriorly as with an apron, and (2) to facilitate their movement upon each other during their vermicular action.

DISEASES OF THE PERITONEUM.—The peritoneum often becomes the seat of dropsical effusion, both in cases of general dropsy and in cirrhosis of the liver. It may also be attacked by cancer, either primary or secondary, and, like all the serous membranes, readily takes on inflammation from various exciting causes. This inflammation is termed *Peritonitis*, and may be either an acute or a chronic disease.

Acute Peritonitis, inflammation of the coating of the bowels, but often popularly spoken of as 'inflammation of the bowels,' generally presents well-marked symptoms. It sometimes commences with shivering, but severe pain in the abdomen is usually the first symptom. The pain is at first sometimes confined to particular spots (usually in the lower part of the abdomen), but it soon extends over the whole abdominal region. It is increased, on pressure, to such an extent that the patient cannot even bear the weight of the bedclothes; and to avoid, as far as possible, internal pressure upon the peritoneum, he lies perfectly still, on his back, with the legs drawn up, and breathes by means of the ribs, in consequence of the pain occasioned by the descent of the diaphragm in inspiration. The breathing is naturally shallow in these cases, and, less air being admitted at each movement of respiration, the number of those movements is increased. There are perhaps forty or even sixty respirations executed in a minute, instead of eighteen or twenty. The pulse is usually very frequent, often 120 or more in the minute, and small and tense, though occasionally strong and full at the commencement of the attack; the temperature is usually raised, and vomiting is almost always an early symptom. After the disease has continued for one or two days

the belly becomes tense and swollen; the enlargement being caused at first by flatus, and afterwards also by the effusion of fluid, as may be ascertained by percussion and palpation. The progress of the disease is in general rapid. In fatal cases death usually takes place within a week, and often sooner. The symptoms indicating that the disease is advancing towards a fatal termination are great distension of the abdomen, a very frequent and feeble pulse, a pinched and extremely anxious appearance of the face, and cold sweats.

Peritonitis is frequently the result of local violence, and of wounds penetrating the peritoneal sac, such as gunshot wounds, surgical operations become septic, &c. In the majority of cases it is due to extension of some inflammatory process in one of the abdominal viscera, particularly the hollow viscera (appendix vermiformis, stomach, intestines, gall-bladder, urinary-bladder, womb). It is sometimes caused by Bright's disease. Two varieties call for special mention: *puerperal peritonitis*, due to extension of septic inflammation of the lining membrane of the womb after child birth or miscarriage, a most fatal form of disease; and *peritonitis from perforation* of one of the hollow viscera, which is characterised by the suddenness of the attack, intense pain arising in some part of the abdomen, the whole of which soon becomes tender in every part. This form of the disease is generally fatal, usually within a few days, unless it be anticipated by early operation upon the organ which forms the source of infection. Perforation of the small intestine, in consequence of ulceration of its glands, is of not uncommon occurrence in typhoid fever, and sometimes occurs in tuberculous ulceration, late in a case of phthisis. The vermiform appendage of the cecum is a comparatively frequent seat of perforation, especially when the appendicitis early takes on a gangrenous or suppurative character. Sometimes it is the stomach which is perforated, and in these cases the patients are usually young women suffering from gastric ulcer, who may have previously appeared in good health, or at most have complained of slight dyspepsia. The organisms found in acute peritonitis are most commonly the bacillus coli; in puerperal cases usually a streptococcus; and occasionally the gonococcus is the cause.

At the onset of the disease it is not always easy to distinguish it from Colic (q.v.), but the progress of the case will soon settle the question. With this exception, the only disease with which peritonitis is likely to be confounded by the well-educated practitioner is a peculiar form of hysteria; but the age and sex of the patient, the presence of hysteria in other forms, and the general history of the patient and of her symptoms will almost always lead to a correct diagnosis of the disease.

The treatment of a case of peritonitis must depend upon the cause to which it is due. Perfect rest in bed is essential. The diet must be light and fluid; in cases of perforation of the stomach no food or even drink must be given by the mouth. Light poultices, or hot fomentations, should be constantly applied to the abdomen. In cases of perforation from disease or injury, and of suppurative peritonitis, immediate surgical intervention to open the abdomen and suture the leaking organ is the proper treatment. In the after-treatment, careful nursing, the position of the patient in bed, the administration of opium, saline aperients, or other drugs as required, all demand the strictest attention.

Chronic Peritonitis occurs in two forms, which differ in their origin and degree of fatality, but are very similar in their symptoms. In the first the inflammation is of the ordinary character, and, although the disease sometimes originates spontaneously, it is more frequently the sequel of an

imperfectly cured acute attack; in the second it depends upon tubercular inflammation. The symptoms of chronic peritonitis are more obscure than those of the acute form. There is abdominal pain, often slight, and not always constant, which is increased by pressure, or sometimes is felt only when pressure is made. The patient complains of a sensation of fullness and tension of the belly, although its size is not visibly increased; of a loss of appetite; and of nausea and vomiting. and the bowels are usually more or less out of order. After a time the abdomen enlarges, and becomes tympanic, or more or less filled with fluid, and at the same time the patient's general debility increases. It is not always easy to determine, during life, whether the disease belongs to the first or second form. When its origin cannot be traced to a preceding acute attack, to local abdominal injury, or to chronic affections of the abdominal viscera, there is strong reason to believe it to be of the tubercular form, especially if the general constitution and the hereditary tendencies of the patient point in the same direction.

In treatment the general remedies for tuberclosis, such as life in the open air, good food, and warm clothing are necessary; tuberculin is often used. The application of stimulating substances to the abdomen, such as iodine or mercurial ointment, helps to cause absorption. In cases which do not improve after some weeks or months of this treatment, opening of the abdomen with drainage and admission of air is often followed by excellent results.

Periwinkle (*Vinca*), a genus of plants of the family Apocynaceae, having a 5 cleft calyx, and a silver-shaped corolla bearded at the throat, with five obliquely truncated segments. The leaves are opposite and evergreen; the flowers grow singly or in pairs from the axils of the leaves. The Lesser Periwinkle (*V. minor*), a native of many parts of Europe and of the southern parts of Britain, growing in woods and thickets, is a half-shrubby plant with trailing stems, rooting at their extremities, ovate-lanceolate leaves, and pale-blue—sometimes white or reddish-purple—salver-shaped flowers. The Greater Periwinkle (*V. major*) which has much larger flowers and ovate cordate leaves, is a native of the south of Europe, and is found in a few places in the south of England. Both of these species are very commonly planted in shrubberies and gardens, rapidly cover unsightly objects with pleasing green foliage, and produce their beautiful flowers at almost all seasons of the year, even in winter when the weather is mild. The Herbaceous Periwinkle (*V. herbacea*), a Hungarian species, is remarkable for the abundance of its flowers. The Rose-coloured Periwinkle (*V. rosea*), a native of Madagascar, is a favorite hot-house plant. The Yellow Periwinkle (*Gelonobus carolinensis*) is a native of the southern parts of North America.

Periwinkle (*Littorina*), a genus of marine Gasteropods, represented by several species on British coasts. The commonest, *Littorina littorea*, is abundant between tide-marks on the rocks, and is often collected and used for food. It is boiled in its shell, extracted as eaten, and is very palatable. Periwinkles crawl about under water, but usually remain passive when left uncovered by the tide. Without water they can survive for many hours, and they are also able to endure a considerable freshening of the salt water. They feed on seaweeds, and are often useful in keeping beds of young oysters from being smothered. Periwinkles drawn up from 70 to 80 fathoms were first in 1889 used as bait for cod-fishing on the banks of Newfoundland. The edible species is oviparous, but in

L. rudis, which is usually common nearer high-water mark, the young are hatched and have a hard shell before they leave the mother. These shells are apt to make this periwinkle gritty, and therefore it is not used as food. Among the structural characters of the periwinkle the substantial shell of few whorls, the closely-fitting, horny operculum, the nearly circular shell aperture without any siphon-notch are at once evident. Species of *Littorina* occur on almost all coasts, and there are about half a hundred in all. It should be carefully noticed that the periwinkle is often called the Wilk, Wulk, or Whelk in Scotland, but it is not nearly related to the true whelks (*Purpura*, *Buccinum*, &c.). See **WHELK**.

Perizzites, the Canaanites of Galilee. See **PALESTINE**.

Perjury is the crime committed by one who, when giving evidence on oath as a witness in a court of justice, or before some constituted authority of the same kind, gives evidence which he knows to be false. But in order to make the giving of false evidence a crime the evidence must be material—i.e. it must affect the decision of some question before the court. If the falsehood occurred as to some trifling or immaterial fact no crime is committed. Moreover, it is necessary, in proving the crime, that at least two persons should be able to testify to the falsehood of the matter, so that there might be a majority of oaths on the matter—there being then two oaths to one. But this rule is satisfied though both witnesses do not testify to one point. The perjury must also have taken place before some court or tribunal which had power to administer the oath (see **OATH**). Though in some courts affirmations are allowed instead of oaths, yet the punishment for false affirmation is made precisely the same as for false swearing. The punishment for perjury was, before the Conquest, sometimes death or cutting out the tongue; perjury is now a misdemeanour, punishable by imprisonment with hard labour. The crime of Subornation of Perjury—i.e. the persuading or procuring a person to give false evidence—is also punishable as a distinct offence; if the false evidence is not given the crime is incitement. In many states of the American Union the crime of false swearing, recognised by common law, is further particularly defined by statute. The violation of an oath of office is not perjury; nor is a false affidavit to an account rendered to an administrator technically perjury, nor false evidence in depositions taken by consent by unauthorised persons.

Perkeniers. See **MOLUCCAS**.

Perlis, a state under British protection on the west coast of the Malay Peninsula N. of Kedah. Area, 316 sq. m.; pop. 40,000 (mostly Malays). See **MALAY STATES**.

Perlitic Structure, in Petrography, is a structure seen in some vitreous rocks. These rocks seem as if made up of little pebbly or enamel like spheroids, each of which is subdivided into a number of concentric coats by curved cracks, roughly parallel to its boundary. The spheroids usually lie packed between rectilinear or curved fissures that traverse the rock in all directions. Perlite is the name given to rocks showing this structure.

Perm, a town of the Ural District of Russia, on the Kama, by which it is 685 miles NE. of Kazan. It is the chief seat of the extensive transit trade between European Russia and Siberia, and has a cathedral, university, tanneries, flour-mills, and oil works, and a government arsenal and cannon-foundry. Pop. 74,000. The region is exceptionally rich in minerals.

Permian System. In Britain this series of strata rests unconformably upon the Carboniferous rocks. It consists of the following groups:

UPPER RED SANDSTONES, clays and gypsum (50 to 100 feet thick in east of England; west of Fennine chain, 600 feet thick).

MAGNESIAN LIMESTONE (500 to 600 feet) = Zechstein of Germany.

MARL SLATE (about 60 feet) = Kupferschiefer.

LOWER RED AND MOTTLED SANDSTONES, with conglomerates and breccias (3000 feet in Cumberland; in the east of England not over 250 feet) = Rothliegendes of Germany.

The Lower Red Sandstones are greatly developed in Staffordshire, Cheshire, and Lancashire, and the Vale of Eden in Westmorland and Cumberland. Small areas also occur in the valleys of the Nith and Annan and in Ayrshire; and similar areas appear in the districts of Down, Tyrone, and Armagh in Ireland. The breccias met with in this group often contain erratics, and have the general aspect of glacial accumulations; and Sir A. Ramsay thought they probably indicate the occurrence of a glacial episode in the Permian period. In the Scottish area the rocks contain sheets of lava-form rocks and tuffs, associated with which are many small filled-up volcanic vents or *necks*. The most important member of the overlying groups is the Magnesian limestone, which is the chief repository of Permian fossils. Many of its beds assume curious concretionary forms, as is well seen on the coast of Durham.

In Germany the Permian consists of an upper and lower group—hence the system is often termed *Dyas*—the Zechstein and Kupferschiefer forming the upper, and the Rothliegende the lower group. Volcanic rocks are associated with the latter. The Kupferschiefer has long been famous for its ores of copper and other metals, and fossil fishes; while associated with the Zechstein are beds of anhydrite, gypsum, rock-salt, and bituminous shales. In Russia the system occupies an area of more than 15,000 sq. m. between Moscow and the Urals. It is well developed in the government of Perm, from which it derives its name. While the German *Dyas* presents the same general features as the Permian of Durham and the east of England, the Russian development resembles the Permians of the Midlands and north-west of England—limestone being quite a subordinate formation, and often wanting. But while most of Northern Europe was land during Permian times, the southern portion of that continent, together with Central Asia, must have been covered by the sea, since they now exhibit a continuous succession of marine deposits from the Carboniferous to the Permian. In North America and Australia similar conditions obtained, and the strata, which include the remarkable coal-bearing series of Australia, are designated Permian-Carboniferous.

Life of the Period.—The Permian strata as a whole are not rich in fossils—the red sandstones, which form so large a portion of the system being for the most part barren. As contrasted with the flora of the Carboniferous period that of the Permian is poor and meagre. But that poverty may be only apparent—the conditions for its preservation not having been so favourable as during Carboniferous times. It may be considered as an impoverished continuation of the Carboniferous flora. The most common plants are ferns—both herbaceous and arborescent—many of the genera being Carboniferous, while others, such as *Callipteris*, are not known as Carboniferous forms. Conifers were likewise numerous, especially the yew-like *Walchia* and the cone-bearing *Ulmmania*. Cycads also flourished, *Pterophyllum* and *Psycophyllum* being forms met with in Permian strata. Finally, it may be noted that many characteristic Palaeozoic types died out in Permian times, such as the *Lepidodendroids*, *Sigillarioids*, and *Cal-*

mites. The animal life of the period is somewhat better represented; but it too appears impoverished when contrasted with that which flourished in the preceding Carboniferous period. We note that rugose corals, so abundant in the older Palaeozoic rocks, are very sparingly met with in Permian strata; even tabulate forms are feebly represented. Polyzoa are fairly numerous in the Magnesian Limestone. Amongst brachiopods the more abundant types are survivals from the Carboniferous, as *Productus*, *Spirifer*, *Strophalosia*. *Lamellibranchs* are somewhat more numerous than brachiopods, common forms being *Schizodus*, *Bukevella*, *Edmondia*, &c. *Gastropods* (*Murchisonia*, *Pleurotomaria*) are feebly represented, and the same is the case with the cephalopods (*Nautilus*, *Orthoceras*, *Cyrtoceras*). It is worthy of note that the trilobites are represented by one form (*Phillipsia*)—the last appearance of that eminently Palaeozoic order. Among the fishes the principal genera are *Palaoniscus* and *Platysomus*. Amphibians seem to have abounded; they are all labyrinthodonts (*Archegosaurus*, *Branchiosaurus*, *Pelosaurus*). At this horizon true reptiles make their earliest appearance.

In most parts of Europe where Permian strata are developed they rest unconformably on Carboniferous and other rocks, from which it is evident that towards the close of Carboniferous times considerable earth-movements took place. These caused the sea to disappear from wide regions in Europe, and resulted eventually in the isolation of certain areas, which thus became inland seas or salt lakes. In these latter mottled sandstones, dolomitic limestones, rock-salt, and gypsum were accumulated, so that the conditions were not favourable to life. One or more such inland seas covered large areas of what is now central England, and extended into southern Scotland and the north of Ireland. Similar large inland seas existed in middle and eastern Europe. The strata accumulated in such basins show plentiful footprints and other indications of shallow-water conditions, such as worm-tracks, sun-cracks, rain pittings, and ripple-marks—evidence which indicates that the level of the lakes was often abnormally lowered during dry seasons, leaving wide tracts exposed over which crawled amellids, amphibians, and reptiles. Volcanic action was rife in Scotland and Germany, and it has been suggested that the abundant and well-preserved fish remains which occur in the Kupferschiefer may have been poisoned by the sudden influx of mineral springs connected with the volcanic disturbances of the time. Some of the inland seas may have had occasional connection with the open sea for longer or shorter periods, as, for example, during the formation of the thicker fossiliferous limestones. But, taken as a whole, the general character of the strata is that of accumulations formed in inland seas. The climate of the period, so far as one can judge from the aspect of flora and fauna, was probably mild and genial. Nevertheless the occurrence of coarse breccias, with their scratched stones and erratics, in the Permian of Britain and the Continent, and the similar appearances met with in strata, which are believed to be of the same age, in India, Australia, and South Africa seem hard to explain without the agency of floating ice.

Permutations and Combinations. A combination, in Mathematics, is a selection of a number of objects from a given set of objects, without any regard to the order in which they are placed. The objects are called elements, and the combinations are divided into classes, according to the number of elements in each. Let the given elements be the four letters *a, b, c, d*; the binary combinations, or selections of two, are *ab, ac, ad,*

bc, bd, cd—six in all; the combinations of three are *abc, abd, acd, bcd*—four in all; while there is only one combination of four—viz. *abcd*.

Permutation, again, has reference to the order of arrangement; thus, the two elements, *a* and *b*, may stand *ab* or *ba*, so that every combination of two gives two permutations; the three elements, *a, b, c*, may stand *abc, acb, bac, bca, cab, cba*, one combination of three thus affording six permutations. The combinations of any order with all their permutations are called the *Variations*. Formulas are given in works of algebra for calculating the number of permutations or combinations in any given case. Suppose seven lottery-tickets marked 1, 2, 3, to 7, and that two are to be drawn; if it is asked how many possible pairs of numbers there are, this is a question of the number of combinations of seven elements, *two* together, which is found to be 21. If we want to know how many times the same seven persons could sit down to table together with a different arrangement each time, this is to ask how many permutations seven objects admit of, and the formula gives $7 \times 6 \times 5 \times 4 \times 3 \times 2 = 5040$. The theory of probabilities is founded on the laws of combination. Thus, in the case of drawing two tickets out of seven, since there are 21 possible pairs, the chance or probability of drawing any particular pair is 1 in 21, or $\frac{1}{21}$. In working out questions in 'combinations' advantage is often taken of the fact that, whatever number of elements be taken from a group to form a combination, the number left gives the same number of combinations; thus, the number of combinations of 10 elements *three* together, is the same as that of 10 elements *seven* together.

Pernambuco, or **RECIFE**, the busiest seaport of north Brazil, stands at the easternmost point of the coast, in $8^{\circ} 3' \text{ S. lat.}$ It consists of three portions, connected by bridges—*Recife* ('the reef') proper, a Dutch-looking quarter, with narrow, winding streets, the chief seat of commerce, on a peninsula; *São Antonio*, a modern quarter, with straight, wide streets, on an island between the peninsula and the mainland; and *Boa Vista*, where are the merchants' villas, on the mainland. Spacious avenues have been made. The principal buildings and public institutions embrace two arsenals, an observatory, the palace of the Archbishop of Olinda (q.v.), law and other schools, &c. The harbour, formed by a reef lying a quarter to half a mile from the coast, is now accessible to great ships. Cottons, machinery, and tobacco are manufactured, and shipbuilding is carried on. There is a lighthouse in the harbour, which is defended by forts. The principal exports are sugar and cotton. Pop. (1878) 94,493; (1920) 238,843. Recife was founded in the second half of the 16th century. Sir James Lancaster captured it in 1595, and the Dutch in 1630. The other two quarters, Mauritsstad (now San Antonio) and Schoonziigt (Boa Vista), were laid out by the Dutch Count Maurice in 1639. The Portuguese captured the town in 1654.—The state has a hot, moist climate; produces sugar and cotton; and has an area of 38,312 sq. m. and a pop. of (1872) 841,539; (1920) 2,154,835. Large portions of the interior still remain in a state of nature, uncultivated and covered with forests.

Pernambuco Wood. See BRAZIL-WOOD.

Pernau (Est. *Parnu*), a seaport of the Baltic, in Esthonia, stands at the mouth of the river Pernau, at the northern extremity of the Gulf of Riga, 100 miles N. of Riga and 80 W. of Dorpat. Besides linseed and barley, it ships large quantities of flax, principally to Great Britain. Pop. 20,000. The university of Dorpat was stationed here from 1699 to 1710.

Pérouse. See LA PÉROUSE.

Perowne, JOHN JAMES STEWART, was born at Burdwan in Bengal, 13th March 1823, of a family of Huguenot origin. He had his education at Norwich grammar-school and at Corpus Christi College, Cambridge, graduated B.A. in 1845, and was elected Fellow of his college in 1849. He was afterwards lecturer for the classical tripos, select preacher, Hulsean lecturer (1868), and Lady Margaret's preacher; professor in King's College, London; and from 1862 till 1872 vice-principal of St David's College, Lampeter. Later he was prelector in Theology and Fellow of Trinity College, Cambridge; preacher at the Chapel Royal, Whitehall; and canon residentiary of Llandaff from 1869 to 1878, when he was appointed Dean of Peterborough. Already, since 1875, he had been also Hulsean professor of Divinity at Cambridge. From 1891 till he resigned in 1901 he was Bishop of Worcester; he died 6th November 1904. A sound Hebrew scholar, he sat throughout in the Company for the Revision of the Old Testament, and was general editor of 'The Cambridge Bible for Schools.' His commentary on the *Book of Psalms* (2 vols. 1864-68) was a masterpiece of exegetical science.

Perpendicular, the name given to the style of Gothic architecture in England which succeeded the Decorated style. It prevailed from about the

Winchester Cathedral—Nave, looking west.

end of the 14th century to the middle of the 16th century, and was thus contemporary with the Flamboyant style in France. These styles have

much in common, but they derive their names from the features peculiar to each. Thus, the Flamboyant (q.v.) is distinguished by the flowing lines of its tracery; whilst the Perpendicular is remarkable for its stiff and rectilinear lines. The lines of the window-tracery are chiefly vertical, and the mullions are frequently crossed by transoms or horizontal bars. The mouldings are usually thin and hard. The same feeling pervades the other features of the style; the buttresses, piers, towers, &c. are all drawn up and attenuated, and present in their shallow recesses and meagre lines a great contrast to the deep shadows and bold mouldings of the earlier styles. The art of masonry was well understood during the Perpendicular period, and the vaulting was admirably built. Fan-tracery Vaulting (q.v.) belongs to this style. The depressed or four-centre arch is another of its peculiar features. In doorways the arched head is frequently enclosed in a square panel over the arch, with spandrels containing shields, quatrefoils, &c. Panneling was also much used, the walls being frequently almost entirely covered with it, as in Henry VII.'s Chapel at Westminster. There are many well-known buildings of this style. Most of the colleges at Oxford and Cambridge belong to it, and in almost every cathedral and church of importance there are some specimens of it—e.g. William of Wykeham's nave at Winchester (q.v.). Open timber-rafters are very common in the Perpendicular style, and are amongst the peculiar and beautiful features of the architecture of England. The roof of Westminster Hall, built by Richard II., is the largest example ever erected.

Perpetual Cure. See CURATE, VICAR.

Perpetual Motion. Formerly the attempts made to 'square the circle' led to an enormous waste of time till mathematicians proved, by repeated and unassailable methods, that the circular area cannot possibly be expressed in terms of the diameter or radius. It logically follows from the definition of a circle that it is a plane figure which does not admit of being squared. In the same way, to all who have understood the words *force* and *motion*, it follows from the definition of a machine that it does not admit of being 'perpetual,' or self-moved. Every machine is constructed to transmit motion or force. The machine, further, modifies the transmitted force, so as to overcome certain resistances, some 'useful' and some 'prejudicial.' In every instance the motion of the machine is derived from without, and the energy so conveyed is to be at once referred to muscular action, or the weight of falling water, or a current of air, or the expansive force of steam, or some other natural power. Some such force is at once implied by the action of any machine, whether the motion is only commencing or has continued for an indefinite time. In an ordinary clock, for example, action is due to the muscular force expended in coiling a spring or raising a weight. The sight of motion in wheels or levers compels us to believe that force has been exerted upon them, and that they are merely vehicles for transmitting it. The machine has gained so much motion and energy, but only at the expense of some exterior agent. The quantity of force in existence being fixed, no new stock can be created, and therefore a self-moving machine is absurd even in name. The practical engineer knows that the force of his steam-engine is exactly in proportion to the amount of coal burned per hour: i.e. the work depends on the consumption of heat. If the mechanical force produced is in excess, however small, of its equivalent (measured by the coal burned), then perpetual motion would be at last found, because then the engine would be generating force—i.e.

giving out more than was derived from the heat of the coal. This, of course, is impossible; it is from the inexhaustible stores of nature alone, such as fire, water, wind, chemical action, and electricity, that force is derived to give motion to any machine whatever. Instead of producing more force than it has received, and so laying up a stock of energy which might render it 'perpetual,' every machine must in its results show less energy than has been transmitted to it. Some of the machine's work is always spent on friction and the atmospheric resistance, so that it cannot give out all the force that was put in.

A 'simple pendulum' swinging in an exhausted receiver, or a top spinning there, might illustrate the term Perpetual Motion, if friction could be avoided. Neither of these, however, could be called a perpetual machine. Give the top some work to do by putting it in gear, say, with a wheel or a crank, and specify its motion slackens; which proves that, for a 'machine,' new force is constantly required from without, especially if anything more than mere motion is required. In the words of the French Academy (*Histoire*, 1775): 'Neglecting friction and resistance (of the air), a body to which motion has been given will retain it for ever, but only on condition that it does not act on other bodies; and the only perpetual motion possible, even on this hypothesis, would be useless for the purpose of the devisers. . . . Numerous mechanics who might have been of great service have wasted (on this kind of research) their means, time, and talents.'

The mere enumeration of all the chief attempts made in various countries to contrive a self-moving machine would be tedious. We shall only note some typical cases in each class. In one class of so-called perpetual machines the essential part was a wheel revolving on a horizontal axis, with several movable weights so distributed round the rim as apparently to act always more on one side than the other, and thus continue the revolution. One of these was by the ingenious Marquis of Worcester, and is described in his *Century of Inventions* as having been tried in the Tower before the king and court. On the same principle was Jackson's machine shown in fig. 1. In other attempts of this class the side of the wheel was divided symmetrically into cells with curved sides, each cell holding a ball which rolled about as the

Fig. 1.

Fig. 2.

revolution took place, so that the balls should, by being further from the centre, act more on one side than on the other, as shown in fig. 2. A foreign instance, described in a letter to Newton as an undoubted success, was that of Orffyreus, consisting of a large wheel covered with canvas. When set in motion the speed increased till it reached a rate of twenty-five revolutions a minute; and when sealed up by the Elector of Cassel it was found at the end of two months to be moving as rapidly as ever. We must of course assume the existence of some imposition in this and more recent cases.

In another class of self-moving machines water or mercury became the prime motor, and was sometimes used in defiance of the most elementary laws of hydrostatics. One of these consisted essentially of a large vessel having a curved tube leading from the bottom up one side and bending over the brim. The inventor actually concluded that the great weight of the liquid in the vessel when full, or nearly so, must force the liquid in the tube up higher than the edge of the vessel, and thus cause a perpetual circulation.

Another class depended on magnetic action, such as Bishop Wilkins's inclined plane up which an iron ball was drawn in a groove by the attraction of a loadstone fixed at the top (fig. 3). Before reaching the loadstone the ball was ingeniously intended to fall through a hole in its path on to a curving incline beneath, and thus be conveyed by a second groove to the foot of the first inclined plane, in order to recommence its upward journey under exactly similar circumstances. The bishop overlooked the fact that the magnetic action would also tend to prevent a fall; but for that fallacy, he had com-

Fig. 3.

Fig. 4.

as near success as the laws of nature permit. In Addeley's perpetual motion the wheel was surrounded by a set of magnets, projecting like teeth in a shunting direction, and having the S poles all towards the centre (fig. 4). Four larger fixed magnets were disposed outside the wheel, two of which at opposite points of the circumference presented their S poles to attract the revolving magnets, while half-way between them the other two presented their N poles to retard them. All the four magnets, however, acted against the inventor's purpose, as well as in the direction which he intended. In fact, if magnetic action or gravity could be temporarily nullified in a particular direction (as light is by interposing an opaque body) the problem of perpetual motion could immediately be solved.

Innumerable patents have been taken out for magnetic and electric machines, but in the principle of each some fallacy lurks, due to a misconception of the laws of force-transmission. A typical case is an electric machine driven by a gas-engine where the latter is heated by the decomposition of water by the electricity produced; just as if a steam-engine, for example, could be heated by the friction of certain bodies set in motion by itself.

Some intelligent and practical proposals have from time to time been made to utilise the rise and fall of tides as the motive power of machines. These, however, should not be classed, as is sometimes done, under those named 'perpetual,' since the supply of power is obviously derived from a natural source—the moon's attraction combined with the earth's daily rotation. A tide-mill, exactly as a water-mill or wind-mill, is entirely dependent on an outward supply of power, and can in no sense be termed self-moving or 'perpetual.' Ultimately, of course, all the forms of natural energy are to be referred to the sun, the

source of planetary force as well as life, whatever be their modifications. See H. Dircks, *Perpetuum Mobile: Search for Self-motive Power* (2d series, 1861-70).

Perpetuity, in English law, means an arrangement whereby property is tied up—i.e. rendered inalienable—for all time or for a very long period. Testators and settlers have always been tempted by family pride to restrain their successors from parting with settled property, especially land; but the policy of the law requires that owners should be free to dispose of their property, and perpetuities are sternly discouraged. Land was formerly tied up by means of Entails (q.v.) and by the creation of remainders, but these forms of disposition were brought within strict rule. Trusts were then used to evade the rules of common law, but the equity courts gradually evolved a rule that property should not be tied up unless for the lives of persons in being and twenty-one years beyond; any disposition which may possibly postpone the vesting of property beyond that period is void. The rule left a settler free, by selecting the lives of young persons, to tie up his property for eighty or ninety years. Thellusson, a London banker, attempted to create an immense fortune by directing that the income of his property should go on accumulating during the lives of his children, grandchildren, and great-grandchildren, living at the time of his death, and for twenty-one years beyond. This led to the passing of what is called the Thellusson Act in 1800: the act restricts accumulation of income (except for payment of debts, &c.) to a period of twenty-one years from the death of the settler, or some other of the limited periods described in the act. It is to be observed that trusts for public and charitable purposes are not, as a general rule, within the scope of the law against perpetuities. In the United States the rules developed by the English courts have been generally adopted as the basis of the law; several states have legislated on the subject, and in some cases the local law against perpetuities has been made a part of the state constitution.

Perpignan, a town of France, and a fortress of the first rank (dept. Pyrénées-Orientales), stands on the river Têt, 7 miles from the Mediterranean, 40 by rail S. of Narbonne, and 17 from the Spanish frontier. It commands the passes of the Eastern Pyrenees, and is defended on the south by a citadel, which encloses the old castle of the Counts of Roussillon, and by a detached fort. The streets are narrow and the houses of semi-Moorish construction, and show evidences of Spanish influence. The cathedral (began in 1324), the Moorish-Gothic cloth-hall or bourse (1396), the town-house (1692), the building of the former university (1349-French Revolution), the palace of justice, and a college are the principal public buildings and institutions. Good red wine is made, sheep and silkworms are bred, vegetables and fruit grown, brandy distilled, cloth woven, and corks cut; and there is a good trade in wine, spirits, wool, cork-bark, oil, cloth, and silk. As capital of the former county of Roussillon Perpignan was in the hands of the kings of Aragon from 1172 to its capture by France in 1475; it was restored to Spain in 1493; but Richelieu retook it in 1642, and France has possessed it ever since. Pop. 54,000.

Perranzabuloe ('Perran in the sands'), a Cornish coast parish, 10 miles N. by W. of Truro. The rude little stone oratory (25 by 12½ feet) of St Piran, who was sent to Cornwall by St Patrick in the 5th century, had been buried in the sands for a thousand years, when it was discovered in 1835; it is probably the earliest ecclesiastical structure in England. Perran Round is a circular

enclosure, with seven rows of seats that could seat 2000, in which miracle plays were performed of old.

Perrault, CHARLES, immortal as the author of 'Puss-in-Boots,' 'Cinderella,' and 'Bluebeard,' was born at Paris, January 12, 1628, the youngest of an advocate's four sons. He was sent at nine to the Collège de Beauvais, but quarrelled with his masters, and had the rest of his education left to chance. He studied law fitfully, and took his license at Orleans in 1651, but soon tired of the humdrum routine of the profession, and filled from 1654 till 1664 an easy post under his brother, the Receiver-general of Paris. In 1663 he became a kind of secretary or assistant to Colbert in matters of architecture and art generally, and for twenty years enjoyed a salary, if not his master's friendship throughout, while by his influence he was admitted to the Academy in 1671. His poem, 'Le Siècle de Louis XIV.,' read to the Academy, and Boileau's angry criticisms thereon, opened up the famous and foolish dispute about the relative merits of the ancients and moderns; to the modern cause Perrault contributed his ambitions but poorly argued *Parallèle des Anciens et des Modernes* (4 vols. 1688-96). The same quarrel inspired his *Éloges des Hommes Illustres du Siècle de Louis XIV.* (2 vols. folio, 102 portraits; 1696-1700), the labour of his latest years. He died May 16, 1703. His *Mémoires* appeared in 1769.

All his writings would already have been for gotten but for the happy inspiration which prompted him to publish in 1697 his eight inimitable prose fairy-tales, the *Histoires ou Contes du Temps Passé*, with the title on the frontispiece of 'Contes de Ma Mère L'Oye.' These had already appeared anonymously from 1696 to 1697 in Moëtjens' *Recueil*, a little miscellany published at the Hague since 1694. The same volume contained a reprint of three tales in verse by Perrault (*Peau d'Âne, Les Souhaits Ridicules, and Grisélidis*), which had already appeared both in Moëtjens' *Recueil* and in small volumes at Paris in 1694-95. The prose *contes*, on the other hand, were expressly stated to be by P. Darnecourt, Perrault's little boy, to whom the 'Privilege du Roy' is granted. M. Paul Lacroix attributes the complete authorship to the son; it is more reasonable to believe with Andrew Lang that, if the naïveté and popular traditional manner point to the conservatism of the child and the native inspiration of his nurse, many a happy touch is due to the elderly academician and wit. But whatever the method of composition of these tales, the resultant is a group of masterpieces in the most difficult of arts, the same judgment of which is renewed generation after generation. It were impertinence to praise these stories; it is enough to enumerate their names: 'La Belle au Bois Dormant' (The Sleeping Beauty); 'Le Petit Chaperon Rouge' (Little Red Riding Hood); 'La Barbe Bleue' (Bluebeard); 'Le Maître Chat, ou le Chat Botté' (Puss-in-Boots); 'Les Fées' (The Fairy); 'Cendrillon, ou la Petite Pantoufle de Verre' (Cinderella); 'Riquet à la Houppe' (Riquet of the Tuft); and 'Le Petit Poucet' (Hop o' my Thumb, Tom Thumb).

See the introduction to Andrew Lang's edition (1888); Charles Deulin, *Contes de Ma Mère l'Oye avant Charles Perrault* (Paris, 1879); Deschanel, *Boileau, Charles Perrault, &c.* (Paris, 1888); P. Saintognes, *Les Contes de Perrault et les Récits parallèles* (1924).

Perry, an agreeable beverage made by fermenting the juice of pears. It is extensively made in Worcestershire, Gloucestershire, Herefordshire, and Devonshire, and forms, with cider, the chief diet-drink of those districts. It contains from 5 to 9 per cent. of alcohol. See **CIDER**.

Perry, OLIVER HAZARD, an American naval officer, born at South Kingston, Rhode Island, 23d August 1785, is famous for his defeat of a British force on Lake Erie in 1813. Perry, who had nine vessels, with 54 guns and 492 officers and men, fought six vessels, with 63 guns and 502 officers and men, lost four-fifths of the crew of his flagship, and finally won a complete victory, which he announced in the brief despatch: 'We have met the enemy, and they are ours—two ships, two brigs, one schooner, and one sloop.' Perry died of yellow fever at Trinidad, 23d August 1819, and was buried at Newport, Rhode Island, where there is a bronze statue (1885). See *Life* by A. S. Mackenzie (New York, 1843), in *Feminist Cooper's Lives of Distinguished American Naval Officers* (1846), and that by Barnes (New York, 1898).

Perryville, a village of Kentucky, about 40 miles SW. of Lexington, was the scene of a hard-fought battle between the Union and Confederate armies of Buell and Bragg, 8th October 1862.

Perse Grammar School, at Cambridge, was founded (1615) by Stephen Perse, M.D. (1548-1615). Jeremy Taylor seems to have been among its first pupils. During Dr W. H. D. Rouse's head-mastership (since 1901) the school has attracted world-wide attention, in great measure owing to his remarkable literary work of the boys under Dr H. Caldwell Cook's play method. See J. M. Gray, *History of Perse School* (1921), and *The Perse Play Books*, ed. H. C. Cook.

Persecution. The principles that underlie the persecution of obnoxious opinions, as opposed to the principles of toleration, are regarded by those who persecute as essentially similar to those that turn justice against the criminal. Persecution of unpopular religious views has on religious or political grounds been especially common. The persecutions of the early Christians by the Roman emperors (see **CHURCH HISTORY**) have been usually, though artificially, counted as ten, viz. under Nero, 64 A.D.; Domitian, 95; Trajan, 107; Hadrian, 125; Marcus Aurelius, 165; Septimius Severus, 202; Maximinus, 235; Decius, 249; Valerianus, 257; Diocletian, 303. Some of the best of the emperors were thus the most strenuous persecutors of the Christians. The persecution seemed in many cases but to fan the zeal of the victims and survivors; in Tertullian's words, the blood of the martyrs was the seed of the church. But there have been many cases in which minor sects have been extinguished, partly or wholly by systematic persecution. The orthodox persecuted the Arians not without success; and the number of Lapsed (q.v.) raised a serious problem in the church. Cathari and Albigenses were practically persecuted out of existence by the Dominicans and the Inquisition; and the measures adopted to suppress the Reformation were triumphant in Bohemia, Spain, and Italy. In the Huguenot wars religion was complicated with politics (see **BARTHOLOMEW, ST**); the Dragonnades (q.v.) were part of a deliberate attempt to crush out Protestantism. The name persecution is used in England specially for the sufferings inflicted by Catholics on Protestants and by Protestants on Catholics in Mary's and Elizabeth's reigns; in Scotland also on the measures used against the Covenanters and other recusants in the 17th century. The oppressive legislation against Independents in Charles I.'s reign may also be classed under this head; and Massachusetts and most of the Puritan colonies passed several repressive measures against the Quakers. The persecutions carried on in the Netherlands by the Spanish authorities (see **HOLLAND**) were especially cruel and persistent. They comprised fine, imprisonment, ban, torture, beheading,

strangling, strangling and burning, burning alive, burying alive; and their continuance goaded the people into a great national revolt. It deserves to be noted that the strenuous denunciation by Voltaire of the persecution of the unfortunate Calas (q.v.) family led to a new chapter in the history of toleration. Furious persecutions extirpated Catholicism from Japan in the middle of the 17th century, and Korea in the middle of the 19th. The Orthodox Eastern Church had in Russia the assistance of the state in repressing the Rascolnik sectaries. Luther and Melancthon were more pronouncedly hostile to the heretical astronomy of Copernicus than the Catholic authorities. A notable case of the persecution of a Protestant by Protestants is that of Servetus (q.v.; see also CALVIN). In this case Calvin had the sympathetic support of many foreign Protestant churches and their leaders. The 'theocratic' system established in Geneva by Calvin so confounded errors, sins, and crimes as to turn the administration of justice largely into a persecuting organisation; in three years there were fifty-eight sentences of death, and over eight thousand imprisonments for the crime of blasphemy. The old Scottish discipline of the kirk-session was regarded as persecuting in spirit long ere it ceased to be rigorously applied. The persecutions of the Jews were especially persistent and especially unsuccessful, and have recurred in recent years in Russia, Rumania, and elsewhere. Nor have the Unitarians been unmolested in Rumania.

See the articles named above, especially INQUISITION and TOLERATION; also ALBIGENSES, AITTO DA FÉ, BLASPHEMY, BRUNO, CANISARUS, CATHOLIC EMANCIPATION, GALLER, HEREST, HUGUENOTS, MOUTON, WATDESSES, WITCHCRAFT; such works as Foxe's *Book of Martyrs* on one side, and on the other Challoner's *Memoirs of Missionary Priests and other Catholics who suffered Death for Religion*; Buckle's *History of Civilisation*; Lecky's *Rationalism in Europe*; and Draper's *Conflict between Science and Religion*.

Perseids. See METEORS.

Persephone. See PROSERPINE.

Persepolis ('Persian City'), the Greek translation of the lost name (*Parsa Karta*?) of the capital of ancient Persia, was situated to the east of the river Medus (Polwar—i.e. Murghab), about 14 miles above its confluence with the Araxes (Bendemir), in the plain of Merdusht, about 35 miles to the north-east of Shiraz, on the road to Isfahán. A series of most remarkable ruins is all that now remains of that city, with which, according to ancient writers, 'no other city could be compared either in beauty or in wealth,' and which was generally designated 'The Glory of the East.' Darius Hystaspes, Xerxes, Artaxerxes, and other Achemenides each in his turn contributed towards its aggrandisement. Alexander the Great in his march of conquest is said to have destroyed Persepolis completely; but this must probably only be understood to apply to some of the chief palaces. It may also be presumed that after the fall of the Achemenides the extension of the original town (afterwards known as Istakhr), on which were situated the royal edifices and the temples used as royal treasuries up to the time of Epiphanes, gradually fell into decay. The

situation of these structures, overlooking the vast luxuriant plain of Merdusht, is described in terms of rapturous enthusiasm by every traveller from Chardin to our own day. Three groups are chiefly distinguishable in the vast ruins existing on the spot. First, the Chehel-Minár (Forty Pillars), with the Mountain of the Tombs (Raelined), also called Takht-i-Jamshid or the throne of Jamshid, after a fabulous king, the reputed founder of Persepolis. The next in order is Naksh-i-Rastam, to the north-west, with its tombs; and the last, the building called the Haram of Jamshid. The most important is the first group, situated on a vast terrace of cyclopean masonry at the foot of a lofty mountain-range. The extent of this terrace is about 1500 feet north and south and about 800 east and west, and it was, according to Diodorus Siculus, once surrounded by three walls of 16, 32, and 60 cubits respectively in height. The whole internal area is further divided into three terraces—the lowest towards the south; the central being 800 feet square and rising 45 feet above the plain, and the third, the northern, about 550 feet long and 35 feet high. No traces of structures are to be found on the lowest platform; on the northern, only the so-called 'Propylæa' of Xerxes; but the central platform seems to have been occupied by the foremost structures, which again, however, do not all appear to have stood on the same level. There are distinguished here the so-called 'Great Hall of Xerxes' (called Chehel-Minár by way of eminence), the Palace of Xerxes, and the Palace of Darius. The stone used for the buildings is dark gray marble, cut into gigantic square blocks, and in many cases exquisitely polished. The ascent from the plain to the great northern platform is formed by two double flights, the steps of which are nearly 22 feet wide, $\frac{3}{4}$ inches high, and 15 inches in the tread, so that many travellers have been able to ascend them on horseback. What are called the Propylæa of Xerxes on this platform are two masses of stone-work, which probably formed an entrance-gateway for foot-passengers, paved with gigantic slabs of polished marble.

Great Staircase to Northern Platform, and Propylæa of Xerxes
Great Hall of Xerxes and Palace of Darius in the distance.

Portals still standing bear figures of animals 15 feet high, closely resembling the Assyrian bulls of Nineveh. The building itself, conjectured to have

been a hall 82 feet square, is, according to the cuneiform inscriptions still extant, the work of Xerxes.

An expanse of 162 feet divides this platform from the central one, which still bears many of those columns of the Hall of Xerxes from which the ruins have taken their name. The staircase leading up to the Chehel-Minār or Forty Pillars is, if possible, still more magnificent than the first; and the walls are more superbly decorated with sculptures, representing colossal warriors with spears, gigantic bulls, combats with wild beasts, processions, and the like; while broken capitals, shafts, pillars, and countless fragments of buildings, with cuneiform inscriptions, cover the whole vast space of this platform, 350 feet from north to south, and 380 from east to west. The Great Hall of Xerxes, perhaps the largest and most magnificent structure the world had ever seen, is computed to have been a rectangle of about 300 to 350 feet, and to have consequently covered 105,000 square feet or 2½ acres. The pillars were arranged in four divisions, consisting of a centre group six deep every way, and an advance body of twelve in two ranks, the same number flanking the centre. Fifteen columns are all that now remain of the number. Their form is very beautiful. Their height is 60 feet, the circumference of the shaft 16, the length from the capital to the torus 44 feet. The shaft is finely fluted in fifty-two divisions; at its lower extremity begin a cincture and a torus, the first 2 inches in depth and the latter 1 foot, from which develops the pedestal, shaped like the cup and leaves of the pendent lotus, the capital having been surmounted by the double half-bull. Behind the Hall of Xerxes was the so-called Hall of the Hundred Columns, to the south of which are indications of another structure, which Ferguson terms the Central Edifice. Next along the west front stood the Palace of Darius, and to the south the Palace of Xerxes, measuring about 86 feet square, similarly decorated and of similar grand proportions.

For a more minute description, see the travels of Niebuhr, Kor Porter, Rich, &c.; Ferguson's *Palaces of Ninveh and Persepolis Restored*, Vaux's *Ninveh and Persepolis*, Rawlinson's *Five Great Monarchies*, Madame Dieulafoy's *La Perse et La Susiane*, M. Dieulafoy's *L'Art Antique de la Perse*, Perrot and Chipiez's *Histoire de l'Art dans l'Antiquité* (v. 1890), and above all, for detailed photographic views, *Persepolis*, by F. Stolze and Th. Noldeke (Berlin, 1882). See also CYRUS, DARIUS, XERXES, CUNEIFORM, and PERSIA (*Persian Architecture*).

Perseus, in Greek Mythology, the son of Zeus and Danaë (q.v.) and grandson of Acrisius. He was brought up at Seriphos, one of the Cyclades, where Polydeutes reigned, who, wishing for private reasons to get rid of him, sent him when yet a youth to bring the head of the Gorgon Medusa, on the pretence that he wanted to present it as a bridal gift to Hippodamia. Perseus set forth under the protection of Athena and Hermes, the former of whom gave him a mirror by which he could see the monster without looking at her (for that would have changed him into stone), the latter a sickle, while the nymphs provided him with winged sandals and a helmet of Hades or invisible cap. After numerous wonderful adventures he reached the abode of Medusa, who dwelt near Tartessus, on the coast of the ocean, and succeeded in cutting off her head, which he put into a bag and carried off. On his return he visited Ethiopia, where he liberated and married Andromeda (q.v.), by whom he subsequently had a numerous family, and arrived at Seriphos in time to rescue his mother from the annoyance of the too ardent addresses of Polydeutes, whom, along with some of his companions, he changed into stone. After this he went to Argos,

from which Acrisius fled to Thessaly, and Perseus assumed the vacant throne. But this, like many other details of the myth, is differently narrated. Perseus was worshipped as a hero in various parts of Greece, and, according to Herodotus, in Egypt too. In ancient works of art the figure of Perseus much resembles that of Hermes. See Hartland, *The Legend of Perseus* (1894-96).

Perseverance of Saints, a doctrine necessarily resulting from the most essential part of the Calvinistic system, and therefore held by almost all who adopt the Calvinistic or Augustinian doctrines. It is advocated not only by arguments from other doctrines, as those of election, atonement, the intercession and mediatorial dominion of Christ, imputed righteousness, and regeneration, but also from many texts of Scripture, as those which declare eternal life to be always connected with believing, and those which encourage the believer to depend on the faithfulness, love, and omnipotence of God. To an objection very commonly urged against it, that it tends to make men careless concerning virtue and holiness, its advocates reply that this objection is valid only against a doctrine very different from theirs, the true doctrine of Perseverance of Saints being one of perseverance in holiness, and giving no encouragement to a confidence of final salvation which is not connected with a present and even an increasing holiness.

Pershing, JOHN JOSEPH, American general, was born 15th September 1860 in Linn County, Missouri, and educated at Kirksville Normal School and West Point. After serving in Indian wars he was professor of military science in Nebraska University, where at the same time he studied law. His personal bravery in Cuba during the war with Spain was much commended, and in 1899-1903 he was in the Philippines where, with the rank of captain, he overcame the Moros. For this service he was made brigadier-general in 1906. In 1909-13 as military governor he had again to subdue the Moros. In 1916 he led the American expedition in Mexico, and he was in command on the border when in 1917 he was sent to the Great War (q.v.) as commander-in-chief of the American Expeditionary Force. In 1921-24 he was chief of staff of the United States army.

Pershore, a pleasant, old-fashioned market-town of Worcestershire, in a great fruit-growing district, on the Avon, 9 miles S.E. of Worcester. Holy Cross, the church of a mitred Benedictine abbey, originally founded in 689, is but a restored fragment—choir, south transept, and central tower, mainly decorated in style, but with Norman and Early English features. Pershore has manufactures of destructors and agricultural implements, and market-gardening is carried on extensively. The first co-operative fruit and vegetable auction-market in England was started there in 1909, and soon became large and successful. Pop. 3000.

Persia, called by its natives IRAN (see ARYANS, &c.), the most extensive and powerful kingdom of western Asia, is bounded on the N. by Turkmenistan, the Caspian Sea, and Transcaucasia; on the E. by Afghanistan and Beluchistan; on the S. by the Strait of Ormuz and the Persian Gulf; and on the W. by Iraq and Turkish Kurdistan. It extends 900 miles from east to west and 700 miles from north to south, and has an area of about 638,000 sq. m. It consists for the most part of a great tableland or elevated plateau, which in the centre and on the east side is almost a dead level, but on the north, west, and south is covered with mountain-chains. The provinces of Azerbaijan, Mazanderan, Gilan, Kurdistan, Luristan, and Fars are almost wholly mountainous.

From the southern boundary of Persian Azerbaijan the majestic range of the Elburz runs eastward, following the line of the Caspian coast at a distance varying from 12 to 60 miles. On reaching Astrabad the mountains sink into ridges of lower elevation, one of which joins the Paropamisus in Afghanistan. A hill-country lies north of this line; it terminates in the Daman-i-koh chain, which sinks abruptly to the low plain of Turkestan. South and east of Azerbaijan a broad mountain-belt traverses Persia from north-west to south-east, the chains and valleys of which it consists lying in the same direction. To this region belong the mountains running from Hamadan to Shiraz, some of the peaks of which are clad with perpetual snow, and the Zagros Mountains and Pushti Kuh on the western frontier. The Persian mountains are mostly primitive; granite, porphyry, felspar, and mountain-limestone enter largely into their composition. They also exhibit indications of volcanic action, Demavend, a conical peak 18,600 feet in height, the highest summit connected with the Elburz range (or ranges), being an extinct volcano; and earthquakes occasionally occur. The Persian plateau, which lies in an angle formed between these mountains, is intersected by many subsidiary ranges and groups of mountains, and spreads eastward to the plateau of Afghanistan, its general elevation ranging from 2000 to 5000 feet above sea-level, the lowest portion being the Great Salt Desert in the south-west of Khorasan, which has 2000 feet of elevation above the sea; while the average elevation of the whole plateau above the sea is about 3700 feet. See ASIA.

A great part of Khorasan, the north half of Kerman, the east of Iraq-Ajemi, which form the great central plain, and detached portions of all the other provinces, with the exception of those on the Caspian Sea, forming more than three-fourths of the surface of Persia, are desert—that is to say, are uncultivated owing to the want of rain and of artificial irrigation. In some parts of this waste the surface produces a scanty herbage of saline plants; in other parts, called *Kerir*, it is covered with an efflorescence of saltpetre, which glitters and flashes in the sunlight, forcing the traveller on these inhospitable wastes to wear a shade to protect his eyes; but by far the greater portion of this region consists of light dry soil, which only requires irrigation to become fruitful. This great central desert contains a few oases, but none of great extent. A narrow strip of low and level country extends along the shores of the Persian Gulf and the Strait of Ormuz. It consists of a succession of bare plains, occasionally interrupted by a plantation of palms near the scanty rivulets which traverse it. It is called Dushistan, or by the generic name, applied to many other localities, of *Gormis*—i.e. the warm region, in opposition to the mountainous districts, called *Sarhad*, or the cold country.

Although so much of Persia is desert, some parts of the country are of exceeding fertility and beauty; the immense valleys, some of them 100 miles in length, between the various ranges of the Kerman Mountains abound with the rarest and most valuable vegetable productions. Great portions of the provinces of Fars, Khuzistan, Ardekan, and Azerbaijan have been lavishly endowed by nature with the most luxuriant vegetation; while the provinces of Gilan and Mazanderan, which lie between the Elburz and the Caspian Sea, and the southern slopes of the Elburz are as beautiful as wood, water, and a moderately hot climate can make them—the mountain-sides being clothed with trees and shrubs, and the plain, 300 miles long by from 5 to 30 miles wide, studded with mulberry plantations, rice-fields,

vineyards, orchards, orange grounds, and sugar and cotton plantations.

Rivers and Lakes.—Persia has hardly one river that can properly be termed navigable, though some of them are several hundred miles in length, and of great width and volume of water. The Karun (q.v.) was opened to foreign steam-navigation from its mouth to Ahwaz (where there is a series of rapids) in 1889. The rivers which flow to the southward receive in the latter part of their course few tributaries, and fertilise only a narrow strip of land on each side of them, except when their waters are applied, by means of canals or other works, to the artificial irrigation of the soil. Most of the monuments of the architectural skill and laborious industry of the ancient Persians in this department are now ruinous. As a natural consequence of the nature and situation of its surface, Persia abounds with saline lakes, and there are nearly thirty of them having no visible outlets. The chief lake is Lake Urmiah (q.v.), in Azerbaijan. Lake Bakhtegan, in the east of Fars, the receptacle for the drainage of the northern half of that province, is sometimes about 60 English miles in length by 9 in breadth. Lake Shiraz is much smaller. Part of Hamun-i-Helmand is included in the frontier of Persia.

Climate and Products.—The climate is necessarily very varied. What the younger Cyrus is reported to have said to Xenophon regarding the climate, 'that people perish with cold at one extremity of the country, while they are suffocated with heat at the other,' is literally true. Persia may be considered to possess three climates—that of the southern Dushistan, of the elevated plateau, and of the Caspian provinces. In the Dushistan the autumnal heats are excessive, those of summer more tolerable, while in winter and spring the climate is delightful. On the plateau the climate of Fars is temperate. About Isfahan the winters and summers are equally mild, and the regularity of the seasons appears remarkable to a stranger. To the north and north-west of this the winters are severe. The desert-region of the centre and east, and the country on its border, endure most oppressive heat during summer and piercing cold in winter. The Caspian provinces, from their general depression below the sea-level, are exposed to a degree of heat in summer almost equal to that of the West Indies, and their winters are mild. Rains, however, are frequent and heavy, and many tracts of low country are marshy and extremely unhealthy. Except in the Caspian provinces, the atmosphere of Persia is remarkable above that of all other countries for its dryness and purity.

The cultivated portions of Persia, when supplied with moisture, are very fertile, producing an immense variety of crops. The chief cultivated products are wheat (the best in the world), barley, and other cereals, cotton, sugar and rice (in Mazanderan), and *tumbaku* or tobacco for the *marghalch* or water pipe. The vine flourishes in several provinces, and the wines of Shiraz are celebrated in eastern poetry. Mulberries are also largely cultivated, and silk is one of the most important products of the kingdom.

The forests of the Elburz abound with wild animals, as wolves, tigers, jackals, boars, buffaloes, foxes, and the Caspian cat. Leopards abound in Mazanderan, and lions in parts of Fars and Arabistan. Among domestic animals the horse, the ass, and the camel hold the first place. The horses have always been celebrated as the finest in the East. They are larger and more handsome, but less fleet, than the Arabian horses. The Caspian rivers abound with fish, especially sturgeon, great quantities of which are cured and exported to Russia. The mineral products of Persia are min-

portant, with the sole exception of oil; salt, iron, and turquoises are worked, as is coal in a very small way; copper occurs in considerable quantity in the mountains of Mazanderan and Kerman; and lead, antimony, and other minerals also abound.

Inhabitants.—The settled population are chiefly Tajiks, the descendants of the ancient Persian race, with an intermixture of foreign blood. To this class belong the agriculturists, merchants, artisans, &c. The Tajiks are Mohammedans of the Shiite sect, with the exception of the remaining Parsees (some 9000 in number), who are found chiefly at Yazd, and still retain their purity of race and religious faith. The Tajiks have been spoken of as timid, cunning, and servile, but against these are to be set industry, and capacity for and love of culture. The nomad or pastoral tribes, or *eylats* (*eyl*, 'a clan'), often spelt *illiyats*, are of four distinct races—Turks (not Osmanli Turk), Kurds, Lurs, and Arabs. Their organisation is very similar to that which formerly subsisted among the Highland clans of Scotland, with the exception that the former are nomad, while the latter inhabited a fixed locality. Each tribe is ruled by its hereditary chief (*ujak*),

thought 40 millions not too high a figure. A recent estimate is 9 millions, including 2 to 3 million nomads. Of cities, Tehrân and Tabriz may have about 200,000; Isfahân and Mashhad, perhaps 60,000 to 80,000.

The houses, those of the wealthiest people not excepted, appear contemptible, being generally built of earth or mud, and are grouped, even in the towns, with little attention to uniformity or order. They scarcely ever exceed one story in height, and they are surrounded by high blank walls. The public buildings, such as mosques, colleges, and caravanserais, are of similar appearance to the ordinary houses, and built of the same materials. The interiors, however, of the houses of the rich are sometimes perfect paradises of luxury and elegance. The miserable look of the towns is, moreover, greatly redeemed by the beauty of the gardens which surround them.

Manufactures and Trade.—The trade of Persia is comparatively of little importance, except the export of petroleum. Silk used to be the great staple, and is produced in almost every province, but chiefly in Gilan, Kashan, and Yazd.

Repeated failure of the crop has, however, interfered very seriously with this industry. Cotton and woollen fabrics, shawls, carpets, and felts are largely manufactured for use and export in different parts of the country. The principal trade centres are Tabriz, Tehrân, Isfahân, Hamadan, and Bushire. Railways have but begun in Persia. Tabriz is connected with the Russian system (by Tiflis), Duzdab with the Indian (by Nushki and Quetta). A line from Bagdad touches the western frontier, and that from Krasnovodsk to Merv the northern. There are short railways at Tehrân (1888; the oldest), Resht, and Bushire. Roads are mostly neglected. Trade-routes, however, for caravans

Isfahân, looking south.

and under him by the heads of the cadet branches (*tirehs*) of his family. Of the four nomad races the Turk is the most numerous, and to it belongs the late Kajar dynasty. The Kurds are few in number, the greater part of their country and race being beyond the bounds of Persia. The Arabs are also few in number, and at the present day can hardly be distinguished from the Persians, having adopted both their manners and language. The Lurs are of nearly pure Persian blood. The nomad races are distinguished from the Tajiks by their courage, manliness, and independence of character; but they are inveterate robbers, and have been the cause of many civil wars and revolutions. There is a small population of native Christians—the Nestorians of Urmiah and Telmâis, and Armenians, whose principal settlement is at Julfa (Isfahân).

We have no certain information regarding the population of Persia. There can be no doubt that in antiquity, and even during the middle ages, while the irrigation-works still fertilised great tracts of country, it supported a great population. In the 17th century the French traveller Chardin

or (sometimes) motor-cars, connect the chief towns with railways and with the ports of the Persian Gulf and the Caspian; and British steamers ply on the Karun as far as Ahwaz. The exports, besides petroleum, consist of carpets, opium, fruits, cotton, silk, skins, wool, wheat, rice, wine, raisins, almonds and nuts, olive-oil, tobacco, drugs, gums; the chief imports are cotton goods, sugar, iron goods, and tea. Russian trade, especially in the north, long rivalled British; but during Russia's troubles it fell off. Now most of the imports come by the Gulf ports, Iraq, and India, though trade with Constantinople and Trebizond by Tabriz is not negligible.

Government, Taxation, Education, &c.—The government was, till 1906, a pure despotism, limited only by the power and influence of the Mohammedan mollahs, domestic intrigues, dread of private vengeance, and an occasional insurrection. The monarch, who has the title of 'Shah' and 'Padishah', possessed absolute authority over the lives and property of his subjects. His deputies, the governors of provinces and districts, possessed similar authority over those under them; their actions were, how-

ever, liable to revision by the Shah, who might summarily inflict any punishment upon them for real or alleged misgovernment. Oppression of the sedentary agricultural classes is almost a necessity of such a form of government. The central government consisted of a ministry, nominally modelled somewhat after the cabinets of European states. Usually, however, the power fell actually, if not nominally, into the hands of one of their number. The Shah, nevertheless, was in reality his own prime-minister, and even trivial matters were submitted for his personal decision. In 1906-9 parliamentary government was introduced. The law both in civil and criminal cases is administered by the governors, who not unfrequently refer points of law, which is based upon the Koran and its commentaries, to mollahs and munshteheds. The punishments commonly inflicted are fines, flogging (the bastinado), and death by decapitation, stabbing, or torture.

Elementary education is very generally diffused among all classes. There are many colleges where students are instructed in religion and Persian and Arabian literature. Among a considerable section of the upper classes it is asserted that the Mohammedan religion is losing its hold, and that unbelief is widely prevalent.

Army.—The standing army is composed of about 30,000 or 40,000 men, in five divisions, with modern armaments. The officers in the Persian army are for the most part ignorant and inefficient, but the soldiers are obedient, sober, intelligent, and capable of enduring great fatigue.

History.—According to the *Shah Nameh* of Ferdusi, the history of Persia begins some thousands of years before the Christian era. Archaeologists, indeed, have found within the limits of the kingdom (at Susa and elsewhere in Elam) one of the earliest known civilisations, which disputes priority with Egyptian and Sumerian. Its painted pottery, perhaps already an old art by 4000 B.C., is declared to be 'among the finest ever made by man.' Little has been done towards extracting the grains of historical truth that may be contained in the mass of fable that constitutes the native Persian annals, and as yet we must rest contented with the accounts derived from Greek writers. The north-western part of Iran, anciently called Media (q.v.), was at the earliest period known to the Greeks a part of the Assyrian empire, but the Medes revolted, and in 708 B.C., under Deioces, established an empire which subdued both that of Assyria and their own kindred tribes of Persis. Hakhamanish (Achaemenes) and his son Chispis (Teispes), king of Anzan or Elam, in the 7th century founded the Persian dynasty of the Achaemenides. Under their descendant Cyrus (q.v.) or Kai-Khusru the Persians rebelled, subdued their former masters, the Medes (who from this time became amalgamated with them), took Babylon (B.C. 539), and established a mighty empire, which extended beyond Persia, as far as the Oxus and Indus, Asia Minor, Syria, Palestine, and Mesopotamia. His son, Cambyses, a most ferocious and bloodthirsty tyrant (529-522), subdued Tyre, Cyprus, and Egypt. After the brief rule of the usurper Smerdis (522-521), Darius I. (q.v., surnamed Hystaspes—the Gushasp of the Persians—521-485) mounted the throne. He was a politic and energetic prince, and succeeded in firmly establishing his dynasty, and adding Thrace and Macedonia to his empire; but his two attempts to subdue Greece were completely foiled, the first by the Thracians, and the second by the Athenians at Marathon (490). His son, Xerxes I. (485-465), renewed the attempt to subdue the Greek states, and, though at first successful, was compelled by the defeats of Salamis and Plataea to limit himself to a defensive warfare, which exhausted the re-

sources of his kingdom. His son, Artaxerxes I. (465-425), surnamed Longimanus (the Bahman of the Persians, better known as Artashir Dirazhist), was a valiant prince, but he was unable to stay the decadence of Persia, which had now commenced. He, however, crushed a formidable rebellion in Egypt, though his wars with the Greeks and Ionians were unsuccessful. The empire now became a prey to intestine dissensions, which continued during the reigns of his successors, Xerxes II., Sogdianus, Darius II., Artaxerxes II., and Artaxerxes III. Darius III. Codomannus (336-329), the last of the dynasty, was compelled to yield his throne to Alexander the Great (known as Iskander or Secunder by the Persians), who reconquered all the former provinces of Persia, and founded a vast empire, which at his death, in 324, was divided into four parts, Persia along with Syria falling to the share of the Seleucidae, and its old dependency, Egypt, to the Ptolemies.

The Seleucidae soon lost Bactria (now Balkh), which became independent under a series of Greek sovereigns; and about 246 Ptothia (q.v.; now Northern Khorasan) also rebelled under Arsaces I., who founded the dynasty of the Arsacidae, under whom the greater part of Persia was wrested from the Greeks, and maintained against both the Greeks and Romans. The Greek empire of Bactria, which is said to have included a great part of India, was overthrown by an influx of nomad tribes from Turkestan (160-140); and these invaders having been driven out by the Parthians, Bactria was added to their empire (138). But the dynasty of the Arsacidae, which maintained itself for four hundred and fifty years, was brought to an end by a Persian named Artashir Babegan, who managed to gain possession of Fars, Kerman, and nearly the whole of Iraq, before Artaban, the Parthian king, took the field against him. At last a great battle was fought (218 A.D.) on the plain of Hormuz, in which the Persians were completely victorious. Babegan was now hailed as Artashir (Artaxerxes), king of Persia, and 'Shahin Shah,' or king of kings, his dynasty being named Sassanide from his grandfather Sassan. The Sassanian kings raised Persia to a height of power and prosperity such as it never before attained, and more than once imperilled the existence of the eastern empire. The most notable kings of the dynasty were Shahpur I. or Sapor (240-273), who routed the Romans, and took the Emperor Valerian captive at Edessa; his grandson, Shahpur II., who also maintained an equal conflict with the Romans; and Chosroes I. and II. (q.v.), the latter of whom was ultimately crushed by Heraclius (q.v.) in 628.

The last Sassanian king, Yazdgerd (Yazdajird), was driven from the throne, after a great battle at Nahavend (639), by the Arabs, who now began to extend their dominion in all directions; and from this period may be dated the gradual change of character in the native Persian race, for they were from this time constantly subject to the domination of alien races. During the reigns of Omar (the first of the Arab rulers of Persia), Othman, Ali, and the Omniades (634-750) Persia was regarded as an outlying province of the khalifate, and was ruled by deputy governors; but after the accession of the Abbaside dynasty (750) Bagdad became the capital, and Khorasan the favorite province of the early and more energetic rulers of this race, and Persia consequently came to be considered as the centre and nucleus of the khalifate. But the rule of the khalifs soon became merely nominal, and ambitious governors, or other aspiring persons, established independent principalities in various parts of the country. Many of these dynasties were transitory;

others lasted for centuries, and created extensive and powerful empires. The chief were the Taherites (820-872), a Turkish dynasty in Khorasan; the Saffarides (Persian, 869-903), in Scistan, Fars, Iraq, and Mazanderan; the Samani, in Transoxiana, Khorasan, and Seistan; the Dilemi (Persian, 933-1056), in western Persia; and the Ghaznevids (see GHAZNI), in eastern Persia. These dynasties supplanted each other, and were finally rooted out by the Seljuks (q.v.), whose dominion extended from the Hellespont to Afghanistan. A branch of this dynasty, which ruled in Khwarezm (Khiva), gradually acquired the greater part of Persia, driving out the Ghaznevids and their successors, the Ghurids; but they, along with the numerous petty dynasties which had established themselves in the south-western provinces, were all swept away by Mongols under Genghis Khan (q.v.) and his grandson, Hulagu Khan, the latter of whom founded a new dynasty, the Perso-Mongol or Ilkhan (q.v.; 1253-1335). This race, becoming effeminate, was supplanted by the so-called Ilkhanians in 1335; but an irruption of the Tatars of Turkestan under Timūr (q.v.) again freed Persia from the petty dynasties which misruled it. After the death of Timūr's son and successor, Shah Rokh, the Turkomans took possession of the western part of the country, which, however, they rather preyed upon than governed; while the eastern portion was divided and subdivided among Timūr's descendants, till, at the close of the 15th century, they were swept away by the Uzbeks (q.v.), who joined eastern Persia to their newly-founded khanate of Khiva.

A new dynasty (Sufi) now arose (1500) in western Persia, the first prince of which (Isma'il, the descendant of a long line of devotees and saints), having become the leader of a number of Turkish tribes who were attached by strong ties of gratitude to his family, overthrew the power of the Turkomans, and seized Azerbaijan, which was the seat of their power. Isma'il rapidly subdued the western provinces, and in 1511 took Khorasan and Balkh from the Uzbeks; but in 1514 he had to encounter a much more formidable enemy—to wit, the mighty Selim, the Sultan of Turkey, whose zeal for conquest was further inflamed by religious animosity against the Shiites (q.v.). The Persians were totally defeated in a battle on the frontiers; but Selim reaped no benefit from his victory, and after his retreat Isma'il attacked and subdued Georgia. The Persians dwell with rapture on the character of this monarch, whom they deem to be not only the restorer of Persia, but the establisher of the faith in which they glory as the national religion—viz. the *Shi'ah*, as distinguished from the *Sunni* sect of Mohammedanism. His son Tamasp (1523-76), a prudent and spirited ruler, repeatedly drove out the predatory Uzbeks from Khorasan, sustained without loss a war with the Turks, and assisted Homayun, the son of Baber, to regain the throne of Delhi.

After a considerable period of internal revolution, during which the Turks and Uzbeks attacked the empire without hindrance, Shah Abbas I. the Great (1585-1628) ascended the throne, restored internal tranquillity, and repelled the invasions of the Uzbeks and Turks. In 1605 he inflicted on the Turks such a terrible defeat as kept them quiet during the rest of his reign, and enabled him to recover the whole of Kurdistan, Mosul, and Diarbekir, which had for a long time been separated from Persia; and in the east Kandahar was taken from the Great Mogul. Abbas's government was strict, but just and equitable; roads, bridges, caravanserais, and other conveniences for trade were constructed at immense expense, and the improvement and ornamentation of the towns were not neglected. His tolerance was

remarkable, as he encouraged the Armenian Christians to settle in the country. Of his successors, Shah Sufi, Shah Abbas II. and Shah Soliman, the two former were sensible and judicious rulers, and advanced the prosperity of their subjects. During the reign of Sultan Hussein, a weak and bigoted fool, priests and slaves were elevated to the most important and responsible offices of the empire, and all who rejected the tenets of the Shiites were persecuted. The consequence was a general discontent, of which the Afghans took advantage to declare their independence and seize Kandahar (1709). Their able leader, Mir Vais, died in 1715; but his successors were worthy of him, and one of them, Mahmud, invaded Persia (1722), defeated Hussein's armies, and besieged the king in Isfahan till the inhabitants were reduced to the extremity of distress. Hussein then abdicated the throne in favour of his conqueror, who, on his accession, immediately devoted his energies to alleviate the distresses and gain the confidence of his new subjects. Becoming insane, he was deposed in 1725 by his brother Ashraf; but the atrocious tyranny of the latter was speedily put an end to by the celebrated Nadir Shah (q.v.), who first raised Tamasp (1729), of the Saffavid race, to the throne, then deposed him and made his young son the nominal sovereign, and finally, on the latter's early death, himself seized the sceptre (1736). But on his death (1747) anarchy again returned; the country was horribly devastated by the rival claimants for the throne; Afghanistan and Belchistan finally separated from Persia, and the country was split up into a number of small independent states till 1755, when a Kurd, named Kerim Khan, re-established peace and unity in western Persia, and by his wisdom, justice, and warlike talents acquired the esteem of his subjects and the respect of neighboring states. After the usual contests for the succession, accompanied with the usual barbarities and devastations, Kerim was succeeded in 1784 by Ali-Muhammad, Jaafar, and Lutf-Ali, during whose reigns Mazanderan became independent under Aga-Mohammed, a Turkoman ennobled of the Kajar race, who repeatedly defeated the royal armies, and ended by depriving Lutf-Ali of his crown (1795).

The great ennobled-king, the first of the dynasty that reigned until 1925, on his accession announced his intention of restoring the kingdom as it had been established by Kerim Khan, and accordingly invaded Khorasan and Georgia. The Georgians besought the aid of Russia; but the Persian monarch, with terrible promptitude, poured his army like a torrent into the country, and devastated it with fire and sword. His conquest was, however, hardly completed when he was assassinated (1797). His nephew, Fath-Ali (1797-1834), after numerous conflicts, fully established his authority, and completely subdued the rebellious tribes in Khorasan. But the great commotions in western Europe produced for him bitter fruits. He was dragged into a war with Russia soon after his accession, and by a treaty concluded in 1797 surrendered to that power Derbend and several districts on the Kur. In 1802 Georgia was declared to be a Russian province. War with Russia was recommenced by Persia at the instigation of France; but, after two years of conflicts disastrous to the Persians, the treaty of Gulistan (1813) gave to Russia all the Persian possessions to the north of Armenia, and the right of navigation in the Caspian Sea. In 1826 a third war, equally unfortunate for Persia, was commenced with the same power, and cost Persia the remainder of its possessions in Armenia, with Erivan, and a sum of 18,000,000 rubles for the expenses of the war. The severity exercised in procuring this sum by taxa-

tion so exasperated the people that they rose in insurrection (1829), and murdered the Russian ambassador, his wife, and almost all who were connected with the Russian legation. The most humiliating concessions to Russia, and the punishment by mutilation of 1500 of the rioters, alone averted war. The death of the crown-prince, Abbas Mirza, in 1833, seemed to give the final blow to the declining fortunes of Persia, for he was the only man who seriously attempted to raise his country from the state of abasement into which it had fallen. By the assistance of Russia and Britain Mohammed Shah (1834-48), the son of Abbas Mirza, obtained the crown. Mohammed resolved to demand reacknowledgment of sovereignty from his alleged vassals in parts of Afghanistan, Beluchistan, and Khiva, but an attempt he made to reconquer Herat, 'the key to India,' was resisted by England. The war was terminated in 1838 by the handing of a small sepoy force on the shores of the Persian Gulf.

Nasir-ed-Din succeeded to the throne on his father's death in 1848. He also resolved to assert his claims in Afghanistan and Beluchistan. The ruler of Herat having recognised the claims of Persia, the English government remonstrated with the Shah, and he was compelled to sign an engagement (1853), by which he became bound not to interfere further with the internal affairs of Herat. In 1856, however, on the pretext that Dost Mohammed, the Amir of Kabul, was about to invade Herat, the Persians again took the city. Thereupon a British army was landed on the coast of the Gulf, and, under Generals Outram and Havelock, repeatedly defeated the Persians, and compelled them to restore Herat (July 1857). Since that time the Persians have not interfered with the 'key to India,' but they have been engaged in a long series of disputes with regard to their frontier north and south of it. After the war of 1857 their encroachments became systematic. In 1868 they occupied Seistan, a province claimed by the Afghans, and extended their jurisdiction over part of Beluchistan; but at length they agreed with the Amir of Afghanistan and the Khan of Kelat to refer the questions in dispute to an English commissioner, General Sir Frederick Goldsmid, who in 1872 fixed the Persian frontier substantially as it now is. The north-eastern frontier was settled by a treaty between Russia and Persia in 1881. The great extension of Russian territory and Russian power on the north-east, while overshadowing Persia, had the effect of sheltering the adjoining regions of Persia from the terrible inroads of the Tekke and other Turkomans. In 1896 Nasir-ed-Din was assassinated, and was succeeded by his second son, Muzaffar-ed-Din, who was in turn succeeded in 1907 by his son, Mohammed Ali Mirza. In 1906 there was a strong movement, supported by the priests, in favour of representative institutions; and in January 1907, after difficulties, hostile intrigues, and risings in the towns, a constitution was formally proclaimed, and the powers and duties of the National Council fixed. The constitution was revoked in 1908 by the Shah, who surrounded the parliament house with troops, who captured and hanged some of the leaders of the democratic party, while others escaped to the British legation. Many houses of Persian nobles were pillaged or destroyed, apparently according to a scheme of proscription. In 1909 the constitution was restored, the Shah fled, and his son Sultan Ahmad succeeded. In 1907 an 'Anglo-Russian agreement' recognised a Russian sphere (including Isfahan and Yazd), a British sphere with the Gulf Coast and Bandar Abbas for its base; the remainder, with Bushire as port, being neutral.

Persia was not a participant in the Great War,

but Turks and Russians fought within her bounds; nor were British troops all removed till 1921. Lord Curzon's treaty of 1919 had brought all Persia much more than ever under British influence. But new stirrings of nationality had begun. In 1921 Riza Khan, a colonel of Persian Cossacks who had risen from the ranks, accomplished a *coup d'état*. Thereafter he was minister of war, whatever changes of government might be made. From 1923 he was also prime minister, with a free hand owing to the Shah's departure for Europe. The Anglo-Persian treaty was denounced (1921), the state strengthened against Russia and Britain alike, the army made efficient, the finances reformed (with American help), and by 1924 feeling against an absentee king of a Turkish dynasty had risen so high that a republic was on the point of being declared. Riza Khan, however, after consultation with the mullahs at Kumi declared a republic irreligious — looking perhaps to recent Turkish history. The Mejlis in October 1925 deposed Sultan Ahmed Shah, and in December, by 257 votes to 3, the prime minister was placed on the throne as Riza Shah Pahlavi. Thus once more a Persian wore the 'crown of Darins,' and the succession which under the Turkish Kajars had been denied to sons of Persian mothers was now confined to these.

Browne, *A Year among the Persians* (1893), and *The Persian Revolution* (1910); Wills, *Land of the Lion and the Sun* (1883); Curzon, *Persia and the Persian Question* (1892); Napier-MacLachlan, *Five Years in a Persian Town* (1905); Ella Sykes, *Persia and its People* (1910); Morier's *Haaji Baba*, also the histories by Sir J. Malcolm (2d ed. 1828), Watson (1866), Sir Clements Markham (1874), and Sir Percy Sykes (1915; revised and enlarged, 1921; a shorter work, 1922); Rawlinson's *Seventh Great Oriental Monarchy* (1876); *The Cambridge Ancient History* (vol. iv. 1926).

PERSIAN ARCHITECTURE.—The architecture of Persia and that of Assyria closely resemble one another, and, owing to the mode and the materials in which they were constructed, their remains serve to illustrate and complete each other's history. In Assyria, where no solid building-materials exist, the walls are composed of masses of sun-dried

Fig. 1.—Plan of Great Hall of Xerxes at Persepolis.

brickwork, lined on the inside, to a certain height from the floor, with large sculptured slabs of alabaster. The Assyrian remains are of palaces, temples, buildings somewhat resembling the Egyptian temples (which were also palaces); and many of the sculptures represent the exploits of the king in war and in peace. The palaces are always raised

on lofty artificial mounds, and approached by magnificent flights of steps (see ASSYRIA, BABYLON).

After Babylon came Pasargadae, where the splendid palaces of Cyrus and Cambyses still exist in ruins, and Persepolis, the capital of Darius and Xerxes (560-523 B.C.); and remains are still to be found at Susa, Ecbatana, and Tehrân. At Persepolis there is abundance of stone, and the pillars, walls, doorways, &c., are still preserved.

The halls at Persepolis were square in plan, having an equal number of pillars in each direction for the support of the roof, which was flat. In the centre a portion was left open for the admission of light, and sheltered by another roof raised upon pillars. The remains of the seventy-two columns with which it was adorned are still extant (fig. 1). The hall had thirty-six columns, six on each side, and on three sides had an external portico, each with two rows of six columns. These columns had capitals, composed of bulls' or horses' heads and shoulders (fig. 2), between which the beams of the roof rested; while others were ornamented with scrolls like the Ionic order (fig. 3). The bases also are suggestive of the origin of that Greek style. This hall was 350 feet by 300, and covered more ground than any similar buildings of antiquity, or any mediæval cathedral except that of Milan. The palaces of Persepolis stand on lofty platforms, built with walls of cyclopean masonry, and approached by magnificent flights of stairs, adorned, like the palaces, with

in its palmiest days rivalled in splendour that of Egypt, Bagdad vying with Cairo, is in many respects a reproduction of the ancient palaces of Nineveh and Babylon. In the mosques thick walls of imperfectly burnt bricks are covered with brilliantly colored decorations of glazed and painted tiles and bricks. Fig. 4 is a view of the

Fig. 2.

Fig. 3.

Details of Persian Architecture.

sculptures somewhat similar to those of Assyria. The interiors were ornamented with paintings. The arches of the gates of Khonsabad spring from the backs of sculptured bulls, and are beautifully ornamented with enamelled bricks. The Louvre has a splendid frieze in coloured enamelled bricks with life-sized figures of warriors from the palace of Darius I., and another similar frieze with lions from the palace of Artaxerxes.

Modern Persian architecture is separated by a wide historic gap from that of ancient Persia, and all posterior to the Moslem conquest belongs to the type known as Saracenic or Arabian. But it seems that the old art of Persia has a more direct influence on that of modern Persia than has been sometimes admitted; and even the Egyptian type of Saracenic art (see ARABIAN ARCHITECTURE) may have been moulded by Persian as well as by Byzantine artists, working for the Moslem conquerors. In Persia itself there seems no doubt that architecture of Mohammedan Persia, which

Fig. 4.—Gateway of Masjid Shah, Isfahân.

gateway of the Masjid Shah, or Great Mosque of Isfahân, dating from the reign of Shah Abbas the Great (1585-1628 A.D.).

PERSIAN LANGUAGE AND LITERATURE.—The ancient and modern idioms of Persia, in general designated as Iranian, belong to the great class of Indo-European languages; but the term Persian itself applies more particularly to the language as it is now spoken, with a few exceptions, throughout Persia, and in a few other places formerly under Persian dominion, like Bokhara, &c. The more important and better known of the ancient idioms are (1) *Zend* (the East Iranian or Bactrian language, in two dialects—the 'Gáthá idiom' and 'ancient' or 'classical Zend'), which died out in the 3d century B.C.—one of the most highly developed idioms, rich in inflections, in the verbs as well as in the nouns, and in the former almost completely agreeing with Vedic Sanskrit; yet such as we find it in the small remains which have survived it is no longer in the full vigour of life, but almost decaying, and grammatically somewhat neglected. Geographically, this idiom may be placed in northern Persia. Its alphabet is of Semitic origin, and the writing goes from right to left (see ZEND, ZEND-AVESTA). (2) *Ancient Persian*, the chief remnants of which are found in the cuneiform inscriptions of the time of the Achemenides, discovered in the ruins of Persepolis, on the rock of Behistun, and some other places of Persia (see CUNEIFORM). Some relics, chiefly consisting of proper names for gods and men, and terms for vessels and garments, have survived in the writings of the classical period, and in the Bible, chiefly in Daniel. This idiom is much nearer to Zend and Sanskrit than to modern Persian. (3) *Pehlvi* (West Iranian, Median, and

Persian), in use during the period of the Sassanides (3d to 7th century A.D.), an idiom largely mixed with Semitic words, and poorer in inflections and terminations than Zend. Its remnants consist of a certain number of books relating to the Zoroastrian religion, of coins and inscriptions; and the language is not quite the same in all cases—according to the larger or smaller infusion of foreign words. The non-Iranian element is known as *Huzvaresht*, and is simply Chaldee; while the Iranian element is but little different from modern Persian. There are three distinct idioms to be distinguished in Pehlevi, and the writing varies accordingly, yet it is not certain whether the difference arises from their belonging to different districts or periods. When, however, Pehlevi ceased to be a living language, and the restoration of the pure Iranian had begun, people, not daring to change the writings (chiefly of a sacred nature, as having descended to them from the Sassanian times), began to substitute in reading the Persian equivalents for the *Huzvaresht* words. At last a new form of commentaries to the sacred writings sprang up, in which more distinct and clear Zend characters were used, where each sign had but one phonetic value, and where all the foreign *Huzvaresht* words were replaced by pure Persian ones; and this new form was called (4) *Pāzend*. The transition from ancient to modern Persian is formed by the *Parsee*, or, as the Arabs and the modern Persians themselves call it, *Farsi*, in use from 700 to 1100 A.D., once the language purely of the south-western provinces, distinguished chiefly by a peculiarity of style, rigid exclusion of Semitic words, and certain now obsolete forms and words retained in liturgical formulas. It is the Persian once written by the Parsees, and is in other respects very similar to the present or *modern Persian* (which also is invariably called *Farsi* by the modern Persians), the language of Jami, Nizami, and Hafiz—from 1100 to the present time—with its numerous dialects. The purest dialect is said to be that spoken in Shiraz and Isfahan and their neighbourhood. In general, the language is pronounced by universal consent to be the richest and most elegant of those spoken in modern Asia. It is the most sonorous and muscular, while at the same time it is the most elegant and most flexible of idioms; and it is not to be wondered at that in Moslem and Hindu realms it should have become the language of the court and of the educated world in general, as French used to be in Europe. Its chief characteristic, however, is the enormous intermixture of Arabic words, which, indeed, make up almost half its vocabulary. Respecting its analytical and grammatical structure, it exhibits traces only of that of the ancient dialects of Zend and Achaemenian, of which it is a direct descendant. The elaborate system of forms and inflections characteristic of those dialects has been utterly abandoned for combinations of auxiliary words, which impart fullness and an incredible ease to speech and composition. The grammar of the Persian language has been called 'regular;' but the fact is that there is hardly any grammar worth mentioning. Thus, there is no gender distinguished in declension; the plural is always formed in the same manner, the only distinction consisting in animate beings receiving the affix *ān*, while the inanimate are terminated in *hā*. Imported Arabic nouns, however, invariably take their Arabic plural. Not even the pronouns have a gender of their own; the distinction between masculine and feminine must be expressed by a special word, denoting male or female. There is no article, either definite or indefinite. The flexion of the verb is equally simple. As to syntax, there is none, or, at all events, none which would not come almost instinctively to any student acquainted

with the general laws of speech and composition. The time of its greatest brilliancy may be designated as that in which Firdausi wrote, when Arabic words had not swamped it to the vast degree in which they have since done, and were still, as far as they had crept in, amenable to whatever rules the Persian grammar imposed upon the words of its own language.

In the history of the Persian writing three epochs are to be distinguished. First, we have the Cuneiform (q.v.), by the side of which there seems, however, to have been in use a kind of Semitic alphabet for common purposes. This, in the second period, appears to have split into several alphabets, all related to each other, and pointing to a common Syriac origin (such as the different kinds of Pehlevi characters and the Zend alphabet) cleverly adapted to the use of a non-Semitic language. In the third period we find the Arabic alphabet enlarged for Persian use by an addition of diacritical points and signs for such sounds as are not to be found in Arabic (*p, ch, zh, g*). The writing is but slightly different from the usual Arabic *Neskh*.

Of the literature of the Persians before the Mohammedan conquest we shall not speak here, but refer to the article *ZEND*. The literary period now under consideration is distinguishable by the above-mentioned infusion of Arabic words into the Persian language, imported together with the Koran and its teachings. The writers are one and all Mohammedans. With the fanaticism peculiar to conquering religions, all the representatives of old Persian literature and science, men and matter, were ruthlessly persecuted by Omar's general, Saad Ibn Abi Wakkas. The consequence was that for the first two or three centuries after the conquest all was silence. The scholars and priests who would not bow to Allah and his Prophet took with them what had not been destroyed of the written monuments of their ancient culture, while those that remained at home were forced to abandon their wonted studies. Yet, by slow degrees, as is invariably the case under such circumstances, the conquered race transformed the culture of the conquerors to such a degree that native influence soon became paramount in Persia, even in the matter of theology. It is readily granted by later Mohammedan writers that it was out of the body of the Persians exclusively that sprang the foremost, if not all, the greatest scholars and authors on religious as well as grammatical subjects, historians and poets, philosophers and men of science; and the only concession they made consisted in their use of the newly-imported Arabic tongue. A further step was taken when the Persians, under upstart native dynasties, returned also to the ancient language of their fathers during the first centuries of Mohammedanism. The revived national feeling, which must have been stirring for a long time previously among the masses, then suddenly burst forth in prose and in verse, from the lips of a thousand singers and writers. The literary life of Persia, the commencement of which is thus to be placed in the 9th century A.D., continued to flourish with unabated healthy vigour for five centuries, and produced a host of writers in every branch of science and belles-lettres, of whom we can only here give the most rapid of surveys, referring for the most important names to special articles.

About 952 Abul Hasan Rudégi, the Blind, rose by the king's favour to such an eminence that he had two hundred slaves to wait upon him; but little has remained of his 1,300,000 distichs, and of his metrical translation of Bidpai's Fables. About 1000 we hear of Kalms, the Dilemite prince, as the author of *The Perfection of Rhetoric*, and poems. In the time of the Ghaznevids, chiefly

under Mahmud, who surrounded himself with no less than four hundred court-poets, we find those stars of Persian song, Ansari (1039), author of *Wamik and Asra*; Ferruchi, who, besides his own poems, wrote the first work on the laws of the Persian metrical art; Esedi, from Tus; and, above all, Firdausi (q.v.), the author of the *Shah-Naméh*. Under the Atabek dynasty was the panegyrist Anhad-ed-Din Anwari, who, with his praise, well knew how to handle satire. Nizami (about 1200) is founder of the romantic epos. Conspicuous in Persia is the mystic (Sufistic) poetry, which, under Anaerontic allegories, in glowing songs of wine and love, represented the mystery of divine love and of the union of the soul with God (see SUIFISM). In this province we find the famous Omar Khayyam (q.v.; died 1123), and Farid-ed-Din Attar (born 1216), the renowned author of *Pend-Naméh* ('Book of Counsel'), a work containing the biographies of saints up to his own time; such is the depth and hidden meaning of his mystic poems that for centuries after him the whole Moslem world has busied itself with commentaries on the meaning of his sacred poetry. He died about 1330, more than a hundred years old, as a martyr. Greater still in this field is Jélal-ed-Din Rumi (died 1273), whose poem on *Contemplative Life* has made him the oracle of oriental mysticism up to this day; he wrote also a great number of lyrical poems. The 13th century cannot better be closed than with Sâdi (q.v.), the first and unrivalled Persian didactic poet. But far above all shines Hafiz (q.v.), who sang of wine and love, and nightingales and flowers. After him the full glory of Persian poetry begins to wane. Among those that came after him Jami (1419-92) stands highest, a poet of most varied genius, second only in every one of the manifold branches to its chief master—in lyric and in didactic to Sâdi, in romance to Nizami, in mysticism to Jélal-ed-Din; but most brilliant as a romantic poet. Of prose works we have by him a history of the Sufis, and an exceedingly valuable collection of epistolary models. Hatîf (died 1785) wrote beautiful odes; and Qâ'ânî (c. 1800) was the most notable of more recent poets. Since 1850 the Bâbis and Bahâ'is have produced poetry full of fire and beauty, as well as powerful and flexible prose. The dramatic poetry of the Persians is not without merit, but is of small extent.

The numerous tales, stories, novels, anecdotes, anthologies, and all the miscellaneous entertaining literature in which Persia abounds form a fit transition from poetry to prose. Able rivals of the great Arabic historiographers sprang up at an early period. For the history of mythical times Firdausi's gigantic epos remains the only source. Reshid-ed-Din, the vizier of Ghazan (born 1247; executed in 1320), wrote a summary of the history of all Mohammedan countries and times, containing besides a complete history of sects. His contemporary Wassaf is the model of the grand rhetorical style. His most successful imitator in the 15th century is Sherif-ed-Din, who wrote the history of Tamerlane. Up to that period pomposity of diction was considered the principal beauty, if not the chief merit, of a classical Persian history. From the 15th century downwards a healthy reaction set in, and simplicity and a striving after the real representation of facts became the predominant fashion. Foremost among the modern historians is Mirkhond, whose *Universal History* comprises the period from creation to the reign of Sultan Hasan Beikara. His son Khondemir also wrote history. Among Indian historians who wrote in Persian we have Mohammed Kasim Ferishtah (1640), who wrote the ancient history of India up to the European conquest, Mohammed Hashim, Abul Fadel Mobarrek, and others. The *Measiri Sultaniye*, which contains

the history of the Kajar dynasty of Persia, and was published at Tehran in 1825, was translated by Bridges (Lond. 1833).

Biographies, legends, histories of martyrs, and the like are legion. Most of the biographies of the Prophet, however, are taken from the Arabic. Works on geography—generally treated together with history—are those of Mestafi, Ahmin Ahmed Rasi, Berishendi, &c. In theology little beyond translations of the Koran, commentaries, and some portions of the Traditions has been produced. Jurisprudence has likewise little to show that is original, and not mere translation, partial commentary, or adaptation in Persian. The *Hedâd-shah*, the *Inadshah*, the *Fatawa Alemgiri* are the most important legal works. Much has been written on medicine, surgery, pharmacy, and physical sciences by Persians, but nearly all their chief works are in Arabic. Mathematics, astronomy, and philosophy have not been neglected; rhetoric, works on letter-writing, and on metrical and poetical arts are numerous. Grammar and lexicography found their principal cultivators in India. Translations from Greek, Indian, Arabic, Turkish, and other languages into Persian exist in abundance.

See E. G. Browne, *Literary History of Persia* (4 vols. 1902-24), and *Press and Poetry of Modern Persia* (1914); Reuben Levy, *Persian Literature: an Introduction* (1923); and books by Reed (Chicago, 1893), Damemester, Ethie, Horn, Dole and Walker (New York, 1901), R. A. Nicholson, J. H. Moulton, as well as the older works by Hammer and Ouseley. See the articles in this work on FIRDAUSI, HAFIZ, OMAR KHAYYAMI, SUIFISM, &c. Dictionaries, besides the native ones, are those of Johnson and Richardson, Vulliamz (1867), Palmer (1876-84), Steingass (1889-92), Wollaston (1889).

Persian Gulf. an arm of the Indian Ocean which penetrates between Arabia and Persia to the extent of 650 English miles in a general north-westerly direction. Its breadth varies from 55 miles at the mouth to 250 miles, and the area is estimated at 77,450 sq. m., not including the islands, which are scattered over the western half, or lie close inshore along the eastern side. The chief of these islands are Ormuz, at the mouth; Kishm, 810 sq. m. in extent; and the Bahrain Islands. The Great Pearl Bank stretches along the western side from Ras Hassan to nearly half-way up the gulf. The coast is mostly formed of calcareous rocks. On the Arabian side it is low and sandy, occasionally broken by mountains and cliffs; while on the Persian side it is higher and abrupt, with deep water close inshore, owing to the mountain-ranges of Fars and Laristan running close to the water's edge. The islands are partly of limestone and partly of ironstone, and are generally destitute of springs, barren, desolate, and presenting numerous traces of volcanic eruptions. Except the Shatt-el-Arab (see EUHRATES), the Persian Gulf receives only insignificant streams. Its eastern side presents abundance of good anchorage, either in the numerous bays or in the lee of islands. The order of the periodic currents in this gulf is precisely the reverse of that of the Red Sea (q.v.) currents, as they ascend from May to October, and descend from October to May. The greatest depth does not exceed 50 fathoms; and Sir John Murray calculated its total cubic contents at 2200 cubic miles of water. Oriental geographers give to this gulf the name of the 'Green Sea,' from a remarkable strip of water, of a green colour, lying along the Arabian coast. Among the ports are Bender Abbas (q.v.), Bushire (q.v.), and Lingah.

Persian Powder. See INSECT-POWDER.

Persigny. JEAN GILBERT VICTOR FIALIN, Duc DE, an adherent of Napoleon III., was born

at Saint-Germain-l'Épinasse (dept. Loire), 11th January 1808, entered the cavalry school at Saumur in 1826, and the 4th Hussars in 1828; but he was expelled from the army for insubordination in 1831. Then, having been introduced to Louis Napoleon, he secured his favour, and commenced a career of Bonapartist propaganda throughout France and Germany. He had the chief hand in the affair of Strasburg (1836) and in the descent on Boulogne (1840), but was captured there, and condemned to twenty years' imprisonment. On the breaking out of the revolution in 1848 Persigny was one of the men who secured the election of Napoleon as President of the Republic; he also took a prominent part in the *coup d'état* of December 1851. In January 1852 he succeeded De Morny as minister of the Interior; from 1855 to 1860 (except for one year) he was ambassador at the English court; then he resumed the office of minister of the Interior until June 1863. In September of the same year he was created duke. Thereafter he sat in the senate until the fall of the empire, when he escaped to England. He died at Nice on 12th January 1872. See his *Mémoires* (1896).

Persimmon. See DATE PLUM.

Persius (AULUS PERSIUS FLACCUS), third in the line of Roman satirists, being later than Lucilius and Horace and earlier than Juvenal, was in some respects the ablest, certainly the most dramatic, of the four. Born of a distinguished equestrian family, 4th December 34 A.D., at Volaterræ in Etruria, he lost his father when six years old, was educated till twelve in his native town, and thereafter in Rome under the grammarian Remmius Palaemon and the rhetorician Verginius Flavius. In early manhood he came under the ennobling influence of the Stoic philosopher Cornutus, who imbued him with the tenets of his school and gave his mind and character an impress which ever deepened and strengthened. But he died before completing his twenty-eighth year (62 A.D.). The admiration and affection entertained by the master for his pupil was shared by the friends of the latter—Lucan, Cæsius Bassus, the lyric poet, and other contemporaries of light and leading, among whom, however, Seneca had little attraction for the young author. The noble and virtuous Pætius Thrasea accompanied him on several tours through Italy, finding a kindred soul in the modest, prepossessing youth, whose integrity and piety were conspicuous in his worldly as in his family relations. The austere discipline of Cornutus affected the style of Persius, who in consequence wrote fastidiously and sparingly, leaving at his death six brief satires, the whole not exceeding 650 hexameter lines. These, slightly corrected by Cornutus and edited by Cæsius Bassus, enjoyed, even through the early mediæval darkness till the Renaissance and down to our own day, the highest esteem, fathers of the church like Augustine and Jerome, humanists like Buchanan and Casanbon, anticipating later schools of literature in evolving and interpreting the poet's pregnant, if sometimes obscure, ridicule of the rapidly degenerating life of 1st-century paganism. The best satire is, on the whole, the first, on the prevailing false taste in poetry. 'Probably no writer ever borrowed so much and yet left on the mind so decided an impression of originality,' says Conington, who further indicates the striking resemblance between the genius of Persius and that of Carlyle. He has had many editors, of whom the most helpful have been Casanbon (1605), Otto Jahn (1843-68), and Conington, whose edition, revised by Nettleship (Oxford, 1878), gives text, prose translation, and notes embodying the best results of previous criticism. G. G. Ramsay (1918) also includes a translation.

376

He has had a host of translators in the chief modern languages—that of the Italian Sacchi of Faenza surpassing all others, not excepting the English versions by Dryden and Gifford.

Person (Lat. *persona*, 'a mask') came to be applied to the person wearing the mask, and thus to mean a personage, an individual, a numerically distinct being. In theology there is a special use of the word for the three Persons of the Trinity (q.v.). The name *Persona*, Person, was first applied to the Trinity by the Latins; the corresponding Greek word, *Πρόσωπον*, being of later use. The earlier Greek Fathers used the word *ὑπόστασις*, 'substance,' where the Latins used *Persona*, and considerable controversy for a time grew out of this diverse use; after the condemnation of the Sabellian heresy, and still more after the Council of Nicea, all ambiguity of words being at an end, the controversy turned upon the substance of the doctrine, in the form of the Arian controversy. See ARIUS.

Personal Equation. See EQUATIONS.

Personal Exception, in the law of Scotland, the equivalent of the English *Estoppel* (q.v.); a ground of objection which applies to an individual and prevents him from doing something which, but for his conduct or situation, he might do.

Personality, as used in philosophy, signifies the distinctive attribute or attributes which distinguish a person from an animal or a thing. A thing we ordinarily consider to be unconscious, an animal to be conscious, a person to be self-conscious. That is to say, we suppose the animal to have intelligent experience of a kind, without being able to reflect upon that experience, and so to be conscious of itself as the unitary subject whose the experience is. The last is the essential mark of personality in the intellectual sphere. 'A person,' says Locke, 'stands for a thinking intelligent being, that has reason and reflection, and can consider itself as itself, the same thinking being in different times and places' (*Essay*, ii. 27). In the moral sphere personality means self-determination or reason-directed will, and may be said to be the foundation of moral responsibility. Hence the central position which it occupies in the ethics of Kant and Hegel. The consciously realised unity and identity of the individual thus constitutes what is most distinctive of personality as such. But under the name of *Double Personality* or *Double Consciousness* the records of medical science contain many cases of mental disorder, in which the sense of personal identity is curiously interfered with. Cases are, of course, of constant occurrence in which the patient mentally affected conceives himself to be some one else (e.g. Napoleon or a Bible character). Others conceive that parts or properties of their frame belong to another person, or that they are inhabited and ruled by a spirit or entity acting in opposition to their will and interests. Others, again, are possessed by the idea that they are two persons at once, or rather that their body is the seat of two beings who are often in strife with one another, one being generally identified more strictly with the self, and the other being regarded as a hostile power and a *malvais sujet* who prompts the better self to evil courses. The struggle between the two persons of this quality often takes bodily shape, and the patient maltreats his own body under the impression that he is castigating the vicious 'other one' who haunts him. This alienation or extrusion of part of the individual's experience from the inner circle of the personality may be due, it has been suggested, to a morbid alteration in the æmesthesia or organic sensations which represent in consciousness the state of the body as a whole. Any part of the body in which this common sensibility is wanting

or disturbed is regarded by the patient as no longer a part of himself, and even as belonging to some hostile being. It even happens in extreme cases of such somatic insensibility that the individual doubts or denies his own existence, as in the case of a patient cited by Ribot, who declared that he had been dead two years, though (according to his own account) he still continued to exist in a mechanical fashion in which he was not consciously interested.

These manifestations, however, are not what is meant by double consciousness in the strict sense of the term. Double consciousness does not necessarily imply the presence of any insane delusion as to the patient's present existence and surroundings, but consists in the fact that a certain portion of his past life is temporarily withdrawn altogether from his conscious memory, to reappear, however, at a later period, when he will have as completely forgotten his present experiences and the whole section of his life connected with them. In the normal human being the memory is unitary, and consequently the life-experiences of the individual are felt and recalled as parts of one whole. In these morbid cases, on the contrary, the conscious life seems, as it were, to be cut into sections or lengths which are entirely disavowed, and retained, so to speak, in separate memories. These mutually exclusive sections are remembered by the individual intermittently in successive periods, generally separated from one another by a swoon, a fit, or some violent nervous crisis. Now, as it is our memory of past experiences that may be said to form the anchor of personal identity, it follows that in such cases we shall have, in greater or less completeness, the extraordinary phenomenon of two separate and independent trains of thought—consequently two separate personalities—in the same physical individual.

Perhaps the most clearly defined and complete instance on record is that of the young American woman reported by Macnish in his *Philosophy of Sleep*. She fell without forewarning into a profound sleep lasting several hours beyond the usual term. Before her sleep she was well informed and possessed an excellent memory. "On waking she was discovered to have lost every trace of acquired knowledge. It was found necessary for her to learn everything again. She even acquired by new efforts the art of spelling, reading, writing, and calculating, and gradually became acquainted with the persons and objects around, like a being for the first time brought into the world. In these exercises she made considerable proficiency. But after a few months another fit of somnolence invaded her. On rousing from it she found herself restored to the state she was in before the first paroxysm, but was wholly ignorant of every event and circumstance that had befallen her afterward. She is as unconscious of her double character as two persons are of their respective natures. For example, in her old state she possesses all the original knowledge, in her new state only what she acquired since. In the old state she possesses fine powers of penmanship, while in the new she writes a poor, awkward hand, having not had time or means to become an expert." A similar experience is observable in the case of somnambulists, who are totally ignorant, in the waking state, of their somnambulist experience, but when again in the somnambulist state recall what happened in the previous crisis. Lost objects have been recovered, and even crimes brought to light by taking advantage of this peculiarity. The same phenomenon is also said to have been observed in cases of intoxication, what is done in one fit of drunkenness being remembered in the next, but forgotten in the sober interval. Instances of double

consciousness, however, are not always of the precise type mentioned by Macnish. Thus, in the case of Felida X., reported by Dr Azam, the woman during the second state was conscious of her whole life-experience, but during the first or original state knew nothing of anything that had happened in the second. The alternations began in this case in 1856, and continued for upwards of thirty years, and it is remarkable that the second state, which at first appeared only in short dream-like periods, gradually supplanted the first state, which came to recur only at long intervals, and for a few hours. The second state was physically and mentally superior to the first, and the patient herself spoke of the first as *état bête*. A still more extraordinary case, reported from Paris, is that of Louis V., a young man of epileptic and hysterical temperament and criminal tendencies (born 1863), where the medical record signalises not two, but six states mutually exclusive, but, taken together, embracing his whole past life. An ingenious literary use of the notion of double personality, on different planes of morality, is seen in R. L. Stevenson's creation of Dr Jekyll and Mr Hyde. See MEMORY (DISEASES OF).

Personality, or PERSONAL PROPERTY, originally distinguished from realty, or real property, by the fact that in the case of realty the thing itself could be recovered, but in personality only damages could be recovered. Furniture, money, stock in public companies, assurance policies, are all personal property, which, unlike real property, is the subject of absolute ownership. On intestacy it was divided among the next-of-kin according to the Statutes of Distribution. By the Administration of Estates Act, 1925 (15 Geo. V. chap. 3), the existing law of succession to personality is abolished. Entirely new rules of succession are enacted. See INTESTACY, KIN (NEXT OF), REAL. In Scots law, the corresponding phrase is Moveables; see HERITABLE AND MOVEABLE.

Perspective (Lat. *perspicio*, 'I look through') is the art of representing natural objects upon a plane surface in such a manner that the representation shall affect the eye in the same way as the objects themselves. The distance and position of objects affect both their distinctness and apparent form, giving rise to a subdivision of perspective into *linear perspective*, which, as its name denotes, considers exclusively the effect produced by the position and distance of the observer upon the apparent form and grouping of objects; while *aerial perspective* confines itself to their distinctness, as modified by distance and light. The necessity of attending to the principles of perspective in all pictorial drawing is apparent when we consider, for instance, that a circle when seen obliquely appears to be not a circle but an ellipse, with its shortest diameter in line with the spectator, and its longest at right angles to this. A square, when looked at from a position opposite the middle of one of its sides, appears as a trapezoid, the sides which are perpendicular to the direction of vision appearing to be parallel, while the other two appear to converge to a point in front of the spectator, &c. For the same reason two rows of parallel pillars of equal height, seen from a point between and equidistant from each row, appear not only to converge at the further end, but to become gradually smaller and smaller. An excellent idea of a perspective plan can be easily obtained by interposing a vertical transparent plane (as of glass—a window, for instance) between the observer and the objects of his vision, and supposing that the objects he sees are not seen *through* the glass, but painted on it. A sketch made on a glass plane in this position by following with a pencil all the lines

and shades of the objects seen through it, the eye being all the time kept quite steady, would form a picture in perfect perspective. In practice, however, it is found unfortunately that glass is not a suitable material for sketching on, and that the vertical position is not the most convenient; it is therefore preferable to make a careful study of the effects produced by change of position and distance on the appearance of objects in nature, and from the results of this to compile a body of rules, by the observance of which painters may be enabled to produce an effect true to nature. After the 'scope' (i.e. the number of objects to be introduced, and the distance at which they are to be

of sight is not, however, necessary, as it occurs only in those cases where the lines, of which the points of distance are the *vanishing points*, are inclined (in nature) at an angle of 45° to the base line; but in all cases the two points of distance are about twice as far apart as the eye is from the picture. One important use of the points of distance is to define the distance of objects in a row (fig. 1) from each other. For this purpose two points of distance are not necessary, as when the position of one pillar is found, that of the one opposite is at once obtained by drawing a line parallel to the base or ground line. We have seen that the point of sight is the vanishing point

Fig. 1.

Illustrating the more important points and lines; P.V.R. is the principal visual ray.

viewed) of the picture has been determined, and before the design is commenced, it is necessary to draw upon the perspective plan three lines: (1) The *base line*, or *ground line*, limits the sketch towards the operator, and is the base line of the picture. (2) The *horizontal line* represents the ordinary position of the sensible horizon. The height of the horizontal line is about one-third of the height of the picture, when the sketcher is placed at or little above the level of the horizon; but it may rise in a degree corresponding to his increase of elevation till it reaches near to the top of the perspective plan. The general rule is to have a high horizontal line when the view is taken, or supposed to be taken, from an eminence; but when the station is on a level, either actual or assumed, as is the case when a statue or a mountainous landscape is figured, the horizontal line must be low. The horizontal line in nearly all cases is supposed to be level with the spectator's eye. (3) The *vertical line* is drawn from the supposed position of the sketcher, perpendicular to the *ground* and *horizontal* lines, meeting the latter in a point which is called the *point of sight*, or centre of the picture. The vertical line has no representative in nature, and is merely a mechanical adjunct to the construction of the picture, all vertical lines in nature being parallel to it in the picture. The point of sight, being the point directly opposite to the observer, is properly placed in the centre of the picture, for it is most natural that the view should be symmetrically on each side of the principal visual line; but this is not by any means a universal rule, for we very frequently find it on the right or left side, but always, of course, on the horizontal line. All lines which in nature are perpendicular to a vertical plane which is raised upon the ground line as a base, meet in the point of sight, which is thus their *vanishing point* (see the line of the tops and bottoms of the pillars in fig. 1). The *points of distance* are two points in the horizontal line on each side of the point of sight, and in a 'direct' sketch are at a distance from it equal to the horizontal distance of the sketcher's eye from the ground line. The equality of distance of these points from the point

of all level lines which meet the ground line or a vertical plane on it at right angles, and that the points of distance (in a *direct* picture) are the vanishing points of all lines which cut the ground line at an angle of 45° ; but there are many other groups of parallel lines in a picture which have different situations, and therefore different vanishing points. Such lines with their vanishing points (called for distinction's sake *accidental points*) are represented in fig. 2. If the accidental point is above the horizontal line, it is called the *accidental point aerial*; if below, the *accidental point terrestrial*; and a little consideration makes it evident that these points may or may not be situated within the plane of the picture. Such are the points and lines necessary for the construction of a plan in true perspective; and from the above

Fig. 2.

The lines O, O converge to the accidental point aerial, and P, P to the accidental point terrestrial.

explanation we may deduce the two general principles: (1) that all parallel straight lines in nature are no longer parallel when projected on the perspective plane, but meet in a point which is called the vanishing point, and is some one of the three above described, unless these lines happen to be also parallel to the ground line or the vertical line, in which case they remain parallel when transferred to the picture; and (2) that, since the bodies drawn below the horizontal line are seen as if from above, those above as if from below, and

those to the right and left of the point of sight as if observed from the left and right, it follows that straight lines which in the picture are above the horizontal line lower themselves, those below raise themselves to it, whilst those to the left, following the same law, direct themselves to the right, and vice versa.

Aerial perspective consists in a modulation of the brightness and colours of objects in accordance with the state of the atmosphere, the depth of the body in the perspective plane (i.e. distance in nature from the ground line), and other accidents of place and time. As the distance of objects increases, their illuminated parts are made less brilliant and their shaded parts more feeble. The bluish tint imparted by a large mass of the atmosphere to the bodies seen through it is frequently imitated by the mixing of a slight tint of blue with the colours to be applied; a yellow object thus assumes a greenish tint, a red one a violet tint, &c. The air when charged with vapour is represented by a diminution of the brightness of colours, and by the grayish tint imparted to them. But in this part of the subject rules are of little avail, for experience alone can guide the painter in faithfully copying the myriad aspects presented by nature.

A thorough knowledge of perspective is a *sine quâ non* to the painter or designer, and though many are inclined to think it a superfluity, and that the sketcher has only to make use of his eyes and copy justly, the very fact that such is their opinion shows that they have never made the attempt; for it is impossible for the painter, and much more so for the designer, to execute a copy of nature with sufficient accuracy by the sole aid of the eye and hand, a fact that is unfortunately much too frequently proved by many of the sketches exhibited in line-art collections. Perspective was known to the ancients, but seems to have become extinct during the disturbances that convulsed Italy, and was revived by Albert Dürer and Bramantino of Milan (c. 1470-1535), whose body of rules was extended and completed by Peruzzi and Ubbaldi about 1600. Dr Brook Taylor in 1715 and 1719 was the first Englishman who discussed the subject scientifically.

Perspiration. See SKIN.

Perth, the county town of Perthshire, on the right bank of the tidal Tay, 43 miles NNW. of Edinburgh, 22 WSW. of Dundee, and 62 NE. of Glasgow. The beauty of its surroundings—the noble river; the two wooded heights, Moncreiffe and Kinnon Hill, 725 and 730 feet high; and, away to the north, the Grampians—makes the 'Fair City' worthy of the name. A handsome nine-arch bridge (1772; widened 1871), 840 feet long, and stretching over a waterway of 500 feet, leads to the suburb of Bridgeend, where Ruskin spent much of his childhood, on the east bank of the Tay; another bridge was built in 1899-1900. Along the west bank extend two beautiful public parks, the North and South Inches, 98 and 72 acres in area. St John's Church is the only old building—a cruciform Decorated pile, with an earlier central square tower. Other edifices are St Ninian's Episcopal Cathedral (1850-90), an Early Middle Pointed structure, by Butterfield; the Tudor municipal buildings (1879), the Greek county buildings (1819-67), the city hall (1844), the infirmary (1837-69), the penitentiary and general prison for Scotland (1812-59), and a museum. Kinnon Hill was given to the town in 1924. Railways have largely diverted the river-trade, and dyeing is now the leading industry, with the manufacture of ink. A royal burgh since 1210 or earlier, taking precedence of all others save Edinburgh, Perth till 1918, when

it was merged in East Perthshire, returned one member to parliament. Pop. (1831) 19,238; (1861) 25,250; (1891) 29,919; (1901) 32,873; (1921) 33,208.

Perth, or St Johnstoun, as it was formerly called, has a wealth of historic memories—the bloody combat on the North Inch between sixty members of the clans Chattan and Kay (1396); the murder of James I. (q.v., 1437); Knox's 'thundering sermon against idolatry' in St John's (1559); the Gowrie Conspiracy (q.v., 1600); and Montrose's victory of Tippecannir (1644); besides sixteen ecclesiastical councils and fourteen parliaments. James, fourth Lord Drummond, was in 1605 created Earl of Perth—a title forfeited in 1695 by the Jacobite fourth earl (titular Duke of Perth), and restored in 1853 to George Drummond, sixth Duc de Melfort.

The *Five Articles of Perth*, memorable in the ecclesiastical history of Scotland, were agreed upon in a meeting of the General Assembly, convened at Perth, by command of James VI. in 1618. They enjoined kneeling at the Lord's Supper, the observance of Christmas, Good Friday, Easter, and Pentecost, and confirmation, and sanctioned the private administration of baptism and of the Lord's Supper. Highly obnoxious to the Presbyterians as having been adopted in mere compliance with the king's will, they yet were ratified by the parliament, and enforced by the Court of High Commission. They became one of the chief subjects of that contention between king and people which produced results so grave and sad for both in the subsequent reign. The General Assembly of Glasgow in 1638 declared that of Perth to have been 'unfree, unlawful, and null,' and condemned the Five Articles.

Perth, the capital of Western Australia (q.v.), occupies a picturesque site on the north bank of the Swan River, 12 miles from Fremantle, its port, at the mouth of the river. Perth is the centre of railway lines to Bunbury and to Albany in the south, to Kalgoorlie and Mount Margaret eastwards, and to Geraldton and the Murchison gold fields to the north. A university was established in 1911 and opened in 1913. Among buildings are the town-hall, the Anglican (1888) and Roman Catholic cathedrals (both archiepiscopal), churches, mechanics' institute and museum, and the governor's residence. Pop. (1881) 5044; (1890) 9617; (1901) 36,274; (1921) 64,166.

Perth Amboy, a city and port of New Jersey, on the Kill van Kull, 21 miles SW. of New York. There is a ferry to Tottenville in Staten Island. Pop. (1885) 6311; (1900) 17,699; (1920) 41,707.

Perthes, FRIEDRICH CHRISTOPH, German publisher, was born at Rindolstadt, 21st April 1772, learned his business in Leipzig, and started on his own account in Hamburg in 1796, and soon pushed himself into the front rank of German publishers. An ardent patriot, he in 1810 started the *National Museum*, with contributions from the most influential writers of the day, and took an active personal part in resisting the establishment of French authority in Hamburg and Germany. Having built up his business again during the first years of peace, he removed in 1821 to Gotha. There his greatest publication was the historical series of works on all European nations, edited by Heeren, Ukert, and Giesebrecht. He died at Gotha, 18th May 1843. See Life (6th ed. 1872; Eng. trans. 1878) by his son Clemens Theodor. -JOHANN GEORG JUSTUS PERTHES (1749-1816), an uncle to Friedrich, established a publishing-house at Gotha in 1785, which has acquired in the hands of his sons a great reputation as a geographical institute; it issues *Petermann's Mittheilungen*, Stieler's *Atlas*

numerous books of travel and geography, and the *Almanach de Gotha*.

Perthshire, the fourth largest county of Scotland, bounded by Inverness, Aberdeen, Forfar, Fife, Kinross, Clackmannan, Stirling, Dumbarton, and Argyll shires. Partly Lowland, but mainly Highland (Strathmore the dividing-line), it is called by Scott 'the fairest portion of the northern kingdom'; and such, indeed, it is, with its mountains and glens, its rivers and lakes, its forests and fertile vales. The chief rivers are the Forth and Tay, the former receiving the Teith, Allan, and Devon, the latter the Tummel, Lyon, Isla, Braan, Almond, and Earn; whilst amongst upwards of eighty lakes are Lochs Tay, Erchie, Earn, Rannoch, Lydoch, Katrine, Achray, Vennachar, and the Lake of Menteith. In the south rise the Ochils, with White Wisp (2110 feet) and Blairdenon Hill (2072); in the south-east the Sidlaw Hills, with Dunsinane (1012) and King's Seat (1235); and the Highland area is largely occupied by the Grampians, of whose forty-six summits exceeding 2300 feet may be mentioned Ben Lavers (with cairn, 4004), Benmore (3843), Ben-y-Gloe (3671), Schiehallion (3547), Ben Volich (3224), Ben Ledi (2875), Ben Vrackie (2757), and Ben Venue (2393). The soil is extremely varied, in places of great fertility—e.g. in Strathearn and in the Carse of Gowrie, which skirts the north side of the Tay's estuary; but barely a fifth of the entire surface is in tillage, the rest being pasture, woods, deer forests, mountain, and desolate moorland, such as Rannoch. The woods cover nearly 100,000 acres; and the deer forests, grouse-moors, and rod and net fishings are valuable. Ancient divisions were Atholl (N.), Rannoch (NW.), Breadalbane (W.), Balquhither (SW.), Menteith (S.), Perth (SE.), Gowrie (E.), Stornont and Strathearn (central). Perth and Kinross return two members, one for the eastern division and one for the western (including Kinross). Perth itself was till 1918 a parliamentary burgh. Other towns and villages are Aberfeldy, Abernethy, Ancherarder, Binnam, Blair-Atholl, Blairgowrie, Callander, Comrie, Coupar-Angus, Crieff, Doune, Dunblane, Dunkeld, Pitlochry, Scone, and Stanley. The Roman camp at Ardoch is a famous antiquity; and Perthshire contains the battlefields of Methven, Tippermuir, Killiecrankie, and Sheriffmuir; whilst it possesses monuments of Bruce, Gavin Douglas, Queen Mary, Rob Roy, Burns, Scott, Lady Nairne, and Wordsworth. The mansions, which are very numerous, include Taymouth (now a hotel), Drummond, and Blair castles. Pop. (1801) 125,583; (1831) 142,166; (1881) 129,007; (1901) 123,283; (1921) 125,515, 5 per cent. Gaelic-speaking.

See separate articles on many of the above-named places; also works by Drummond (1879), Marshall (1880), Hunter (1883), and Millar (1890).

Pertinax, HELVIUS, Roman emperor, was born, according to Dio Cassius, at Alba Pompeia, a Roman colony of Liguria, August 1, 126 A.D. He received a good education, and, entering the military service, rose through the various grades till he obtained the command of the first legion, at the head of which he signalled himself in Rhetia and Noricum against the native tribes. In 179 he was chosen consul, aided to repress the revolt of Avidius in Syria, and was governor successively of the provinces of Mœsia, Dacia, and Syria. The Emperor Commodus sent him to take the command of the turbulent legions in Britain, who against his will proclaimed him emperor; thereupon he solicited to be recalled, and was appointed pro-consul of Africa, prefect of Rome, and consul (a second time) in 192. On the death of Commodus his assassins almost forced Pertinax to accept of the purple, which with great

hesitation he did; but, in spite of his promise of a large donation, he was unable to gain over the praetorian guard. His accession was, however, hailed with delight by the senate and people, who were rejoiced to have as ruler an able captain instead of a ferocious debauchee; and Pertinax, encouraged by this favourable reception, announced his intention of carrying out an extensive series of reforms, having reference chiefly to the army, in which he hoped to re-establish the ancient Roman discipline. Unfortunately for his reforms and himself, he was attacked by a band of the rebellious praetorians, two months and twenty-seven days after his accession, and, disclaiming to flee, was slain, and his head carried about the streets of Rome in triumph.

Perturbations, in Physical Astronomy, are the disturbances produced in the simple elliptic motion of one heavenly body about another by the action of a third body, or by the non-sphericity of the principal body. Thus, for instance, were there no bodies in space except the earth and moon, the moon would describe accurately an ellipse about the earth's centre as focus, and its radius-vector would pass over equal areas in equal times; but only if both bodies were homogeneous and truly spherical, or had their constituent matter otherwise so arranged that they might attract each other as if each were collected at some definite point of its mass. The oblateness of the earth's figure, therefore, produces perturbations in what would otherwise be the fixed elliptic orbit of the moon. Again, when we consider the sun's action it is obvious that in no position of the moon can the sun act equally upon both earth and moon; for at new moon the moon is nearer to the sun than the earth is, and is therefore more attracted (in proportion to its mass) than the earth—i.e. the *difference* of the sun's actions on the earth and moon is equivalent to a force tending to draw the moon away from the earth. At full moon, on the other hand, the earth (in proportion to its mass) is more attracted than the moon is by the sun; and the perturbing influence of the sun is again of the nature of a force tending to separate the earth and moon. About the quarters, again, the sun's attraction (mass for mass) is nearly the same in amount on the earth and moon, but the *direction* of its action is not the same on the two bodies, and it is easy to see that in this case the perturbing force tends to bring the earth and moon nearer to each other. For any given position of the moon, with reference to the earth and sun, the *difference* of the accelerating effects of the sun on the earth and moon is a disturbing force; and it is to this that the perturbations of the moon's orbit, which are the most important, and amongst the most considerable, in the solar system, are due. See MOON, PLANETS, &c.

Peru (Span. *República del Perú*), a republic of South America, which, before annexations by Chile (Tarapacá permanently; Tacna and Arica conditionally) after the war of 1879-81, stretched southward to 22° 10', with a length along the Pacific coast of 1400 miles, and a width of 300 miles. It borders on the Pacific, Ecuador, Colombia, Brazil, Bolivia, and Chile. The area is roughly estimated at 700,000 sq. m. There has been no census since 1876, but the population (believed to be stationary owing to infant mortality and other causes) was in 1896 stated at about 4,600,000; the aboriginal Inca Indians forming 57 per cent., the *Mestizos* or half-castes 23 per cent., and the people of pure Spanish descent, negroes, Chinese, &c., 20 per cent. Peru is still the country of the Inca people.

Surface of the Country.—The surface of Peru is extremely varied. It is divided longitudinally into

three well-marked regions. (1) The *Coast* extends from the base of the Andes to the Pacific Ocean, and consists of a sandy desert crossed at intervals by rivers, along the banks of which there are fertile valleys. (2) The *Sierra*, or region of the Andes, about 250 miles wide, contains stupendous chains of mountains, elevated plains and tablelands, warm and fertile valleys and ravines. (3) The *Montaña*, skirting the eastern slopes of the Andes, is the third region. It consists of tropical forests traversed by great tributaries of the Amazon. The coast region has been upraised from the ocean at no very remote period. The absence of rain on this strip of land between the mountains and the sea is caused by the action of the lofty uplands of the Andes on the trade-wind. Reaching the snow-capped summits the last particle of moisture is wrung out of the wind that the very low temperature can extract, and it rushes down to the Pacific coast, cool and dry. Its moisture is deposited as snow on the tops of the cordillera, and feeds the mountain-streams which flow down to irrigate the coast-valleys. From November to April there is usually constant dryness on the coast, from June to September the sky is obscured for weeks by mist, sometimes accompanied by drizzling rain. The maximum temperature is about 78° in summer and 60° in winter. When it is hottest and driest on the coast it is raining heavily in the Andes, and the rivers are full. When the rivers are lowest mists and *garuas* or drizzling rains prevail on the coast. The deserts are divided from each other by forty valleys of great fertility, and the cultivable area on the coast might be considerably extended by irrigation. The coast has few protected anchorages, and the headlands are generally abrupt and lofty. This region is subject to frequent and severe earthquakes, the most destructive in modern times having been that of 1868, which nearly destroyed Arequipa and Arica, and that of 1877. Since 1570 there have been about a hundred destructive earthquakes recorded on the west coast of South America.

The Peruvian Andes contain peaks attaining heights of 21,000 and 22,000 feet; but they have never been measured with scientific accuracy. The mountain-system consists of three chains or *cordilleras*. Two of these chains, running parallel and near each other, are of identical origin. The western one is the maritime cordillera and comprises the volcanoes. The eastern cordillera is a magnificent and almost continuous range, in great part of Silurian formation, with clay-slates and eruptive granitic rocks. The western cordillera is cut through by several streams which flow into the Pacific, and the eastern cordillera by six tributaries of the Amazon, but the central chain is an unbroken water-parting. It consists mainly of crystalline and volcanic rocks, on each side of which are strata of aqueous, in great part of Jurassic, rocks. The valleys and plateaus between these ranges form the *Sierra* of Peru, and include every variety of climate and scenery. They may be divided, from a geographical point of view, into four sections, commencing from the north. The first, 350 miles long by 100 broad, comprises the upper basins of the Marañón and Huallaga. The second extends for 200 miles from Cerro Pasco to Ayacucho, including the lake of Chichay-cocha and the valley of Jaaja. The third extends for 250 miles to the knot of Vilcañota, comprising the upper valleys of the Apurimac, the Vilcanuya, and the Paucartambo. Here is Cuzco, the capital of the Incas, the centre and heart of Peru. The fourth section is the basin of Lake Titicaca, about 150 miles in length and breadth. The lake itself is 80 miles long, and 12,545 feet above the level of the sea. A number of rivers, which are of con-

siderable volume during the rainy season, fall into it, and it is drained by the Desaguadero flowing out of the south-west angle. But a great proportion of the water is also taken up by evaporation, and the waters are gradually receding. The Sierra of Peru is the original home of the potato. Its lofty heights also produce several other edible roots and the grain called *quinoa* (*Chenopodium quinoa*), while splendid crops of maize are grown in the valleys. The animals which specially belong to the Peruvian Sierra are the domestic llamas and alpacas, and the wild vicuñas. The llamas were the beasts of burden in the time of the Incas, each carrying a weight of about 100 lb. Alpacas have always been prized for their long and soft wool, and are tended with great care, being kept in large flocks. The other animals of the Peruvian Sierra are the *taruro* or deer, two rodents called *viscachas* and *chinchilla*, a native dog, and a fox. The largest bird is the condor, and there is another bird of the vulture tribe called *alecomari*. Partridges, called *yutu*, and plovers are met with on the lofty plateaus. The large and handsome geese called *huachua* and *huallata*, several ducks, a gull, flamingoes, and other wading-birds frequent Lake Titicaca and the banks of the rivers. In the valleys there are many kinds of finches, and a green parakeet has been seen at a height of 12,000 feet above the sea.

The *Montaña* is the region of tropical forests within the basin of the river Amazon, including the wooded slopes of the eastern watershed of the Andes, which may be called the subtropical portion of the *Montaña*. This part of Peru is traversed by great navigable rivers. Here the Marañón and Huallaga, after separate courses of 600 and 400 miles respectively, unite and flow eastward to the Brazilian frontier. At 150 miles from their point of junction they are increased by the waters of the Ucayali, a great navigable river with a course of 600 miles. The forests drained by the Marañón, Huallaga, and Ucayali form the northern portion of the Peruvian *Montaña*. The southern half is watered by streams flowing down from the eastern Andes in the Sierra sections of Cuzco and Titicaca, and forming the Madre de Dios, a great tributary of the Bolivian river Beni. The whole length of the Peruvian *Montaña*, from the Marañón to the Bolivian frontier, is 800 miles. In the subtropical portion, comprising the eastern slopes of the Andes, which sometimes extend for a distance of 60 or 80 miles before they subside into the Amazonian plain, there are very important products. This is the region of the quinine-yielding cinchona-trees, and of the coca (*Erythroxylon Coca*), and here coffee and cacao of the finest quality are cultivated. From the forest-covered plains come india rubber, sarsaparilla, and a great variety of useful and ornamental timber. The *fauna* of the forests is naturally much more numerous and varied than that of the Sierra. Here are the silver-gray monkey, the largest in South America, and other species. Bats of several kinds are numerous, and there are flocks of coatis. The Andean bear, called *unumari*, is found on the upper borders of the forests. The puma also roams over the higher slopes, where he has an almost undisputed hunting-ground. Lower down there are jaguars, and several kinds of wild cats. Squirrels and other rodents swarm, and the heavy tapir, called *danta* or *gran bestia*, reposes in the soft marshy lands. Deer frequent the open ground, and herds of peccaries traverse the forests. The chief game-bird is the large black curassow, and there are several pigeons. Spoonbills, ibis, cranes, snipe, and curlew frequent the lagoons, while parrots, toucans, and other birds of bright plumage are innumerable. Snakes abound among the dense

underwood, frogs raise their far-sounding voices through the night, and insects swarm in myriads.

Productions and Commerce.—The chief crops of the fertile coast valleys are sugar, cotton, and grapes. Peruvian cotton is chiefly grown in the valleys of Piura and Ica, and is a perennial. The vine has been a profitable industry ever since the Spanish conquest, in several valleys on the coast, and also in the Sierra. Good wine is made at Pisco and Ica, and also a famous spirit from the grape, called *Pisco* and *Italia*. There are also grown cinchona, coca, and other medicinal plants. Rice of excellent quality is raised in the coast-valley of Lambayeque. Olives are grown in the Tumbó valley near Arequipa. The rocky islets and barren deserts of the coast were once a source of enormous wealth to Peru, and some Guano (q.v.) is still got. Petroleum has become the chief mineral product. It is worked in the extreme north, but occurs elsewhere, as about Lake Titicaca.

The staple exports of the Sierra of Peru are copper, silver, and wool. The mines extend along the whole length of the cordilleras, and are worked here and there, the great centre of mining industry being at Cerro Pasco. Other minerals are gold, vanadium (of which Peru is the chief source), coal and iron (not much worked), mercury, bismuth, and borax.

From the Montaña the exported products are cinchona bark, coca, coffee of the finest quality, cacao, tobacco, india-rubber, saúparilla and some other medicinal roots. Rubber is sent down the Amazon from Iquitos. The atrocities of the trade in the Putumayo district were notorious in 1908-13. Plantations are now superseding the collection of wild rubber. Other Peruvian products are tobacco, maize, wheat, fruits, balata, and castor-oil.

Public Works.—The system of railways consists of a dozen short lines in the coast-valleys—varying in length from 80 to 20 miles, constructed to bring the produce down to the seaports—and of two long lines across the Andes. The first of these, from Callao and Lima to Oroya, in the lofty valley of Janja, was begun in 1870. It threads the intricate gorges of the Andes by a winding path along the edges of precipices, through tunnels, and over bridges that seem suspended in the air. It tunnels the Andes at an altitude of 15,645 feet, and the bridge of Verrugas (q.v.), 250 feet high, spans a chasm 580 feet wide. Oroya is the junction for Huancayo and Cerro de Pasco. The other line across the Andes runs from the port of Mollendo by Arequipa to Juliaca and Cuzco, while from Juliaca a branch goes to Puno on the shores of Lake Titicaca. The summit is crossed at a height of 14,660 feet. In 1874 steamers were first launched on Lake Titicaca. To supply the port of Mollendo with water, a pipe was laid alongside the line from Arequipa for 85 miles, discharging 433,000 gallons in twenty-four hours—one of the longest iron aqueducts in the world.

The People.—The bulk of the Peruvian population is composed of the aboriginal Inca Indians, whose language, called Quichua, is still spoken in the Sierra. The Incas had attained to a high state of civilisation before the arrival of the Spaniards. They cultivated many of the arts, and had some knowledge of astronomy. They had domesticated the llama and alpaca, had brought under cultivation maize and quinoa, potatoes and many other edible tubers, understood mining and the working of metals, and excelled as masons, weavers, potters, and farmers. They brought the science of government to a high pitch of perfection. The Incas composed songs and dramas; and as soldiers their skill and prowess enabled them to conquer and consolidate a vast empire. Four centuries

of oppression under Spanish rule have debased the character of the Inca Indian, but he is still industrious and honest, and retains some of the virtues of his ancestors. The wild Indians of the Montaña were never subjugated by the Spaniards. Spanish administration caused a rapid diminution of the population. The Indians of the coast-valleys disappeared altogether. Negro slaves were then introduced to cultivate the estates in these valleys, and this system continued during Spanish colonial rule, and until 1855, when slavery was abolished.

Church and Education.—The constitution of 1920 declares absolute religious liberty, the state religion being Roman Catholic. When the Spaniards conquered Peru the Catholic religion was enforced on all natives, and a determined attempt was made to crush out the modes of thought, traditions, and culture of the Inca civilisation, and to substitute new ideas and beliefs. This destructive system was resolute and well organised, and was in great part successful. Education and literature were in the hands of an intolerant priesthood. The cruel Friar Valverde was made Bishop of Cuzco in 1534. The archbishopric of Lima was created in 1541, the bishoprics of Guamanga, Arequipa, and Trujillo were added in 1612 and 1614, and others later. Swarms of clerics followed the bishops, numerous monasteries were founded, and an inquisitorial system of catechising and punishing penetrated into every village and hamlet in the land. Schools were established in the towns for the education of young Spaniards and half-castes; and the university of San Marcos at Lima, the most ancient in the New World, was founded in 1551. It had professorial chairs of medicine, philosophy, rhetoric, Latin, mathematics, divinity, and for a short time of Quichua. The college of San Carlos at Lima, which still flourishes, was founded in 1770, and the school of medicine was established in 1792. At Cuzco the university of San Antonio Abad was founded in 1598, and the viceroy, Prince of Esquilache, also endowed the college of San Borja there, for the education of noble Indians. At Arequipa the college of San Jerónimo was founded in 1616, for teaching Latin and theology, and similar colleges were founded at Trujillo in 1621 and at Guamanga in 1680. There are now four universities: Lima, Cuzco, Arequipa (1827), and Trujillo. Education is (nominally) compulsory for both sexes and is free in the municipal public schools, yet but a fraction of the population has attended any school. Peru can make a respectable show in literature. In recent times it has produced José Santos Chocano and José María Eguren.

Constitution.—Under the constitution of 1920 Peru has a president elected for five years and re-eligible for a second term; a senate of 35 members and a house of representatives of 110 members, both directly elected by male citizens for five years.

History.—From very ancient times there were agricultural communities in the Sierra of Peru, gradually advancing in the arts of government and of peace, and there were people of a different race in the coast-valleys, who were also civilised. The plants they had brought under cultivation, and the animals they had domesticated, are among the proofs of the great antiquity of Peruvian civilisation. Eventually all the different communities were united under one empire, and the Incas, in the course of some five centuries, developed a highly centralised system of government. Civilisation never attained to such a height among any other of the indigenous races of America. The Incas attempted the administration of a purely socialistic government, and their attempt was successful. The great Inca Huayna Capac died, after a long and prosperous reign, at

about the time when Pizarro first visited Tumbes. On his death there was a war of succession between his two sons, which had just terminated in favour of Atahualpa when Pizarro (q.v.) landed a second time and marched into the interior. Peru was soon overrun by the Spaniards, and the beneficent rule of the Incas came to an end. At about the time of the assassination of Pizarro the representations of Las Casas (q.v.) respecting the cruel treatment of the Indians had obtained a hearing, and the 'New Laws' were promulgated. The grants conceded to the conquerors were not to be hereditary, all men who had been engaged in civil wars were to be deprived, and personal service from Indians was forbidden. Blasco Nuñez Vela was sent out to Peru as viceroy to enforce these reforms. He landed in 1544, and proclaimed the 'New Laws.' The Spanish conquerors were thrown into a state of exasperation and dismay, and appealed to Gonzalo Pizarro (q.v.) to leave his retirement and protect their interests. The result was that the viceroy was defeated and killed, and Gonzalo virtually became governor of Peru. But he was not recognised by the Spanish government, and an ecclesiastic named Pedro de la Gasca was despatched to Peru, with a commission to restore order. Gonzalo Pizarro was defeated near Cuzco, and beheaded on the battlefield. Gasca reversed the humane legislation advocated by Las Casas, and made a hasty distribution of grants to his followers. The announcement of his awards caused much discontent, but Gasca hurriedly sailed for Spain in January 1550, leaving the country in a most unsettled state, in the hands of the four judges who were his colleagues. He had arranged that the emperor's decree against forced labour should be promulgated after he was safe out of the country. This gave rise to a formidable rebellion, led by Francisco Hernandez Giron. The judges made head against it, but it was not put down until two pitched battles had been fought, and Giron had been beheaded at Lima in December 1554.

The Marquis of Cañete arrived as viceroy of Peru in May 1555. His policy was to employ the unquiet spirits among the Spanish settlers on expeditions of discovery into unknown regions, and to treat the natives with liberality and justice. During the five years of his government he restored order among the conquerors, and established the heir to the Incas in a dignified retirement. But it was Don Francisco de Toledo, the viceroy from 1569 to 1580, whose legislation finally fixed the colonial policy of Spain in this part of the New World. He reversed the kindly treatment of the ancient dynasty which had distinguished the Marquis of Cañete, and unjustly beheaded young Tupac Amaru, the last of the Incas, at Cuzco in 1571. At the same time he wisely based his legislation on the system of the Incas. His elaborate code, called the 'Libro de Tasas,' was the textbook of all future viceroys. He fixed the amount of tribute to be paid by the Indians, exempting all males under the age of eighteen and over that of fifty. He recognised the position of the native chiefs, assigning them magisterial functions, and the duty of collecting the taxes and paying the money to the Spanish officials. But he enacted that one-seventh part of the population of every village should be subject to forced labour, generally in the mines. This was called the *Mita* system.

It was the habitual infraction of the rules established by Toledo, and the abuse of the *Mita*, which caused all the subsequent misery and depopulation of the country. Compliance with the continual demand for treasure from Spain, a demand which was insatiable, was incompatible with humane treatment of the people. For more than

two centuries the people of Peru toiled and died. At length their sufferings became intolerable. They rose as one man in the autumn of 1780, and a descendant of the Incas, taking the revered name of Tupac Amaru, placed himself at their head. After a long and formidable resistance the insurgents were finally subdued, and their leader was put to death under circumstances of revolting cruelty. But he did not die in vain. In his fall he shook the colonial power of Spain to its foundation. From the cruel death of the Inca Tupac Amaru may be dated the rise of that feeling which ended in the expulsion of the Spaniards from South America. Some of the demands of the Inca were conceded soon after his death. He was the foremost pioneer of the independence of Peru. The desire for liberty among Peruvians of Spanish descent had its birth in Lima; but Lima was the residence of the viceroy. Here the power of Spain was concentrated. Consequently it was in the more distant colonies of Buenos Aires, Caracas, and Chile that insurrectionary movements first broke out and that independence was first secured.

At length a fleet under Lord Cochrane (see DI DONALD), equipped in Chile, brought the Argentine General San Martín to Peru with troops, and the independence of the land of the Incas was proclaimed at Lima on the 28th of July 1821. Another liberating force, from Colombia, under General Bolívar, embarked at Guayaquil, and when the Liberator arrived at Lima, in September 1823, San Martín retired. The Spanish viceroy, La Serna, with his army, retreated into the interior, and the patriots followed on his heels. On 9th December 1824 the decisive battle of Ayacucho was fought, the Spanish viceroy and all his officers were made prisoners, and the colonial government finally gave place to a free republic. Bolívar and his Colombians left the country in 1826, but it was eighteen years before the government became settled. In August 1829 General Gamara, a native of Cuzco and a hero of Ayacucho, was elected president of Peru, but at the end of his term of office there were troubles which culminated in an attempt to form a Peruvian-Bolivian Confederation under General Santa Cruz. This was defeated by Peruvian malcontents, aided by a Chilean army, the cause of Santa Cruz and his confederation having been ruined after the decisive battle of Yungay on 20th January 1839. Gamara again became president, the confederation was dissolved, and a constitution was proclaimed. But Gamara fell in a deplorable war with Bolivia, and the contentions of his officers caused a succession of civil wars until 1844.

At length a man arose who restored peace to the distracted country. Ramón Castilla was a native of Tarapacá, and was a veteran of Ayacucho. He was brave as a lion, prompt in action, and beloved by his men. His firm grasp of power secured a long period of peace. He was elected constitutional president of Peru in 1844, and ten years of peace followed. Castilla commenced the payment of interest on the foreign debt in 1849. A revised constitution was promulgated in 1856, and the slaves were emancipated. Castilla retired from office in 1862, and died in 1866. The next important event was the election of Colonel Balta. This president held office from 1868 to 1872, during which time public works were undertaken on a gigantic scale with the aid of foreign loans. Don Manuel Pardo, a scholar and a man of letters as well as a statesman, was the first civilian president. He held office from 1872 to 1876, and inaugurated a policy of retrenchment. But it was too late to save the credit of the state, and the payments of interest on the loans ceased in 1876. Pardo reduced the army, regulated Chinese immigration, promoted the exploration of navigable rivers in

the Montaña, organised an efficient plan for the collection of statistics, and actively encouraged literature and education. He was the best president Peru had ever known, and in August 1876 he was peacefully succeeded by General Prado.

In 1879 Peru was confronted with the overwhelming misfortune of a Chilean invasion. Chile coveted the nitrate deposits in the Peruvian coast province of Tarapacá. A successful defence of Peru depends on the mastery of the sea. Peru had two old-fashioned ironclads. Chile had two new ones. One of the Peruvian ships was wrecked. The other, commanded by the heroic Admiral Grau, a native of Piura, was captured, after a most gallant defence, maintained against the combined attack from the two Chilean ships. On the 8th October 1879 he and nearly all his officers fell in defence of the *Huáscar*, the ship on which the fate of their country depended. Tarapacá was occupied after the loss of two well-contested battles. In 1880 the battle of Tacna sealed the fate of that department; and, after the two desperate battles of Chorrillos and Miraflores in 1881, Lima itself was occupied. Public works were demolished and private estates devastated along the coast, and in Lima the valuable public library was destroyed. General Cáceres still kept up a resistance in the interior.

In 1883 the Chileans induced one of the Peruvian leaders, Iglesias, to submit to their terms. In October he signed a treaty of peace and was allowed to enter Lima. Tarapacá was ceded to Chile; Tacna and Arica were to be held by Chile for ten years, after which a popular vote should decide their fate; the country chosen paying the other \$10,000,000; and there were some articles, favourable to Chile, respecting the guano-deposits. The Chileans evacuated Peru in August 1884, and their nominee, Iglesias, followed them in December 1885. On 31 June 1886 General Cáceres, who had gallantly defended his country against the Chileans from first to last, became constitutional president of Peru. His policy was retrenchment and the protection of the Indian population. Payment of interest of the foreign debt had become impossible. But a scheme was arranged in 1890 by which the foreign bondholders formed a company to receive all the railways for a term of sixty-six years (since extended), with mining, and other privileges. In return the company is to complete the railway system, and cancel the debt through the profits. Peru was slowly recovering from the disastrous effects of a great calamity, when in 1894-95 another insurrection broke out, and a new government was established. Negotiations as to the method of voting for or against the retrocession of Tacna and Arica fell through. Constitutional reforms followed a revolution in 1919. The long-standing dispute with Chile was submitted to President Coolidge's arbitration in 1922. In 1925 he gave his award. The Chileans had not wilfully prevented the holding of the plebiscite, nor had their administration made a fair plebiscite impossible. The river Sama was the northern boundary of the area, the province of Tarata being unquestionably Peruvian. General Pershing and representatives of both countries were appointed to supervise the plebiscite, but found it impossible to carry out owing to the kidnapping and assassination of voters by the Chileans.

For the history of the Incas and their civilisation, see the works of Cieza de Leon, Molina, Balboa, Garcilaso de la Vega, Montesinos, and Acosta, all, except Montesinos, translated into English for the Hakluyt Society; also Rivero's *Antiquidades Peruanas* (with Von Tschudi, Vien, 1851), of which an English translation appeared at New York, Joyce's *South American Archaeology* (1912), Bingham's *Inca Land* (1923), Lehmann and Doering's *Art of Old Peru* (trans. 1923); and the histories of

Robertson, Prescott, Helps, Winsor (vol. i.), and Markham (1892, 1910), and the travels of D'Orbigny, Squier, Wiener, and Reuss and Stabel. For the Conquest, see, besides Robertson, Prescott, and Helps, the narrative of Xerez, Pizarro's secretary (Sage, trans. Hakluyt Soc.), and the writings of Herrera, Gomara, Zarate, Pedro, Pizarro, and Fernandez. For the period of the viceroys, see Figueroa's *Life of the Marquis of Cútepe*, the *Chronicle of Calancha*, and the *Memorias de los Virreyes*; also the works of Don Ricardo Palma, published at Lima, and Saldamando's *History of the Jesuits in Peru*. The documents relating to the great rebellion of Tupac Amaru were published by Angelis at Buenos Aires, and there are further particulars in the work of Dean Funes; see also Weddell's *Voyage dans le Nord de Bolivie*, and Markham's *Travels in Peru and India* (1862). For the war of independence, see works by Stevenson, the Chilean author Vicuña Mackenna, General García Camba, the Memoirs of General Miller (Lond. 1828), the Autobiography of the Earl of Dundonald, and the great biographical work of General Mendiburn; for the war with Chile, narratives from the Chilean point of view by Barros-Arana and Mackenna, and from the Peruvian by Paz-Soldán, and Markham's *History of the War between Peru and Chile* (1883). For the geography, the *Geografische Peru*, by Paz-Soldán, and the 3 vols. on Peru by Raimondi are important works. See also Von Tschudi's *Kechua Sprache* (1853), Markham's *Quechua Grammar and Dictionary* (1863), Middeldorff, *Die erbkennischen Sprachen Perus* (1890 et seq.).

Peru. (1) a city of Illinois, at the head of navigation on the Illinois River, 100 miles by rail WSW. of Chicago. It has zinc-works, and makes ploughs and ice. Pop. 9,000.—(2) Capital of Miami county, Indiana, on the Wabash River, and on the Wabash and Erie Canal, 75 miles by rail N. of Indianapolis. Pop. 12,000.

Perugia, a city of Italy, stands (1617 feet above sea-level) on the right bank of the Tiber, 11 miles E. of the Lago Trasimeno (anc. *Lacus Trasimenus*) and 127 miles by rail N. of Rome. It is surrounded by medieval walls, which in part coincide with and in part extend beyond the ancient Etruscan enceinte, several of the gates of which still exist, notably the so-called Arco di Augusto. The broad Corso, which contains the handsomest edifices, unites two squares, in one of which stands the Gothic cathedral of St Lawrence, dating from the 14th and 15th centuries, and adorned with many works of art. The church of St Dominic (1632) contains the tomb of Pope Benedict XI. (author unknown) and a magnificent stained-glass window (1411-59); the remarkable church of St Peter (11th century) has granite pillars, and pictures by Pergino, &c., and other works of art; these are only two out of several noteworthy churches. In the cathedral square stand also the Gothic municipal palace (1281-1443), with the valuable art gallery, especially rich in productions of the Umbrian school; the great fountain, adorned with statues by Niccolò and Giovanni Pisano; the statue of Pope Julius III. (1555); and the old money-changers' hall (1452-57), decorated with some of Pergino's best works. In the vicinity of the city a number of Etruscan tombs were discovered in 1840; they contained cinerary urns, lamps, vases, bronze armour, ornaments, &c. The tomb of the Volturni (3d century B.C.) is interesting. The university (1307) has a botanical garden, an observatory, a valuable antiquarian museum, and a library (1852) of 30,000 vols. There is also an academy of fine arts, with an art school. Silk and woollen goods, wax-candles, chocolate, and liquors are manufactured. Pop. (1921) 72,998. Perugia, the ancient *Perusia*, was one of the twelve Etruscan republican cities. It was besieged and captured by the Romans in 310 B.C., and again in 40 B.C., and by Totila (549). At different periods during the next thirteen centuries it was subjected to the popes, especially after the middle of the 16th cen-

tury; at other times it was independent, though in the power of native despots. In the 15th century it became the centre of the Umbrian school of painting. See *The Story of Perugia*, by Miss Symonds and Miss Duff Gordon (1898), and Crick-shank's *Umbrian Towns* (1901).

Perugia, Lake of. See TRASIMENE LAKE.

Perugino, a celebrated Italian painter, whose real name was PIETRO VANNUCCI, was born at Città della Pieve in Umbria, in 1446, but established himself in the neighbouring city of Perugia (see G. C. Williamson's *Perugino*, 1900). He executed important works, no longer extant, at Florence, Perugia (1475), and Cerqueto (1478). At Rome, whither he went about 1483, Sixtus IV. employed him in the Sistine Chapel; his fresco of 'Christ giving the Keys to Peter' is the best of those still visible—others by him being destroyed to make way for Michelangelo's 'Last Judgment.' During his next sojourn at Florence (1486-99) he had Raphael for his pupil. Here he was fined for waylaying and assaulting a citizen, and became somewhat too fond of money, repeating his works and leaving much of the execution to pupils. At Perugia (1499-1504) he adorned the Hall of the Cambio, with the assistance of Raphael and other pupils; but after 1500 his art visibly declined. In his second Roman sojourn (1507-12) he also, along with other painters, decorated the Stanze of the Vatican; and one of his works there, the Stanza del Incendio, was the only fresco spared when Raphael was commissioned to substitute his works for those formerly painted on the walls and ceilings. The new school, with Leonardo da Vinci, Michelangelo, and Raphael, was now in the ascendant, and Perugino's popularity waned. He was again at Perugia in 1512, and painted a number of pictures there. He was painting frescoes in a church at Castello di Fontignano, near Perugia (one of which frescoes is now at South Kensington), when he was seized by the plague, of which he died in 1524.

Perugino's art was religious, though he is said by Vasari (biased in all regards by Michelangelo's contempt for Perugino) to have been an open disbeliever in the immortality of the soul. In his figures, very unequally drawn, there is a peculiar tenderness of expression verging on mawkishness; his execution was delicate, his colour admirable. But he is not remarkable for originality or intensity.

Peruvian Bark. See CINCHONA.

Peruvian Gooseberry. See WINTER-CHERRY.

Pervigillum Veneris, a Latin poem of singular beauty, with the irregularly recurring refrain 'Cras amet qui nunquam amavit, quique amavit cras amet.' Author and date are unknown—perhaps 1st century A.D., perhaps 5th. Translated into English by Thomas Stanley and by Thomas Parnell, it has been edited by Bücheler (1850), Clementi, Dobson, Mackail, Fort (1922), and Postgate (1924), the four last with translations.

Pesaro (the ancient *Pisaurum*), a town of Italy, stands on the right bank of the Foglia, here crossed by an ancient bridge, 1 mile from the Adriatic and 37 miles NW. of Ancona by rail. Its streets are broad, and adorned with palaces and churches, and the town is surrounded with walls and defended by a citadel (1474) and a fort. It is a bishop's seat; there are two cathedrals, one new, the other old. Silks, pottery, iron, and leather are manufactured; and an active trade is carried on in these goods and in wine, olive-oil, and fruits. Pop. 30,000. The city is associated in literary history with the name of Tasso, some of his MSS. being preserved in one of the town museums; it is

also the birthplace of the composer Rossini. Made a Roman colony in 184 B.C., it was destroyed by the Goths; then, having been rebuilt by Belisarius, it became one of the cities of the Pentapolis. From 755 to 1285 it belonged to the popes, then to the Malatestas till 1445, then to the Sforzas (who built the fine Villa Imperiale, outside the town) and Della Rovere, in 1631 again to the popes, and finally in 1860 to Italy.

Pescadores Islands. See FORMOSA.

Peschiera, on the site of the ancient Arilica, a fortress of Italy, a member of the Quadrilateral (q.v.), stands partly on an island in the Mincio partly on the right bank of that river, at its outlet from the Lake of Garda, 14 miles by rail W. of Verona and 77 E. of Milan. The fortress played a prominent part in the warlike events which have taken place in North Italy, especially after the Napoleonic wars began down to 1859, but it is now without military value. Pop. 3000.

Peshawar, or PESHAWUR, a town of India, the capital of the North-west Frontier Province, 10½ miles from the entrance of the Khaiber Pass, 190 E. by S. of Kabul. Although occupying a strategic position of the utmost importance, its only defences are a wall and a small fort; but 2 miles west of the city are cantonments. The population in 1921 was 104,452, including the cantonments. Peshawar is the seat of extensive commerce between Afghanistan and India; gold, silver, lace, hides (all four from Bokhara), horses, mules, fruits, woollen and skin coats (all five from Kabul) being exchanged for tea, English piece-goods, wheat, salt, rice, butter, oil-seeds, oil, and sugar.

Peshito (Syriac *peshittā*, 'the simple'), the Syriac Vulgate. See BIBLE.

Peshwa. See MAHARATTAS.

Pessimism is the doctrine that on the whole the world is bad rather than good. It does not necessarily mean that the world is the worst possible of all conceivable worlds, as the fact of its being the verbal opposite to Optimism, the term employed to describe the Leibnitzian philosophy, would seem to imply; it means simply that the world is so bad that it would be better if it did not exist. Pessimism presents itself in a twofold aspect—(1) as a settled attitude of mind or permanent mood of feeling, and (2) as a philosophical system. The former springs out of the contemplation of the antagonism that exists in the world between natural laws and moral laws, between the world as it actually is and the world as it ought to be; it is the outcome of reflection, and is largely conditioned by individual temperament. Thus it is coeval with the dawn of conscious intelligence, and early found fit literary expression. The problem of the existence of evil, the connection between suffering and sin, is the burden of the ancient Hebrew Book of Job; and the Jewish thinker who wrote Ecclesiastes rings the changes upon the nothingness of life, and sums up his plaint in the hopeless refrain, 'Vanity of vanities, saith the Preacher, all is vanity.' Different forms of the same temper of mind are given utterance to with more or less of moral indignation in Innocent III.'s *De Miseria Humanae Conditionis*, and the satirical works of Juvenal and Carlyle and others. The same 'world-sadness' (*Weltsehmerz*), though expressed in more personal and passionate language, colours deeply the poetry of Omar Khayyam, Leopardi, Heine, and Byron; and the negation of the problem, 'Is life worth living?' forms an undercurrent in much of our best modern literature. But the pessimistic temper, culminating in the persuasion of the nothingness and vanity of human life, has had more than an individual expression; it has entered deeply

into the substance and structure of two of the world's greatest religious beliefs—viz. Christianity and Buddhism. The Christian is familiar with the doctrine that this earthly life is a vale of tears and woe, and that its pleasures and joys are illusory, being always accompanied with sin and suffering and evil, from which he can only escape by fixing his hopes upon a better life in the world to come. Buddha's practical teaching (see *BUDDHISM*) turns in great part upon the desire to escape from the sorrows of life and the deceptive illusions of existence (*maya*).

But here, in this latter point, the pessimistic mood assumes something of a philosophical character. It also enters, though principally as an unconscious element, into the philosophical doctrines of the Stoics and the Neoplatonists, in that they regarded man's sensual (sense) nature as opposed and inferior to his intellectual. The medieval mystics (Eckhart) combined the religious with the philosophical tendencies of the mood that 'despise the earth,' but not in a conscious, deliberately philosophical fashion. But it is only in the most recent times that pessimism has been elaborated into a philosophy or complete theory, in the systems of Schopenhauer (q.v.) and his successor, E. von Hartmann (q.v.). Schopenhauer is generally considered to be the father of philosophical pessimism: he regards the world principle as an omnipotent, blindly struggling and striving Will, which is incapable of satisfying itself or of delivering itself from its eternal cyclic misery. Hartmann formulates as world principle the Unconscious, whose primal error, for which it eternally atones in the endless misery of the world, was its kindling—just as Schopenhauer's Will did—a light for itself in the brain, or the consciousness of organised life. Both philosophers build on the pain and misery and struggle which they see everywhere in the world, from chemical decomposition and stellar movement up through the endless struggle of organisms for existence to the acute suffering exhibited in the many forms of human passion, and chiefly of all in exalted passionate love or sexual desire (*Romeo and Juliet*, or *Kubala and Liebe* of Schiller); and to both all this is only the outward expression of the terrible, irrational, or non-logical cosmic agency. It is extremely difficult to state shortly the metaphysical grounds of pessimism; they are far from being merely superficial, and may be said to be rooted in the old antitheses between nature and man. Nature thwarts man at all points, and modern science has shown us what a small twig human life is on the great tree. Both Schopenhauer and Hartmann lay a firm hold on the fact (emphasised especially by Schopenhauer in opposition to Hegel and to theism) that not only the Idea or Logos must be used in replanning the world, but also Force, Impulse, Will, Strife. Thus in a sense they represent the substitution of the scientific or cosmic attitude towards the world for the merely introspective attitude of a Descartes or a 'common-sense' moralist. It is not, of course, in the least to be assumed that what we call 'naturalism,' as opposed to speculation or supernaturalism, leads to pessimism, mental and spiritual facts being just as ultimate as chemical protoplasm. The full force of pessimism lies in the assertion that all the ends and aims of life are illusory, that life, in fact, brings only illusion; the illusion of illusions being man's innate and inveterate belief that he is born to be happy and to have pleasure. There are here two main contentions: (1) All ends are illusory, even cosmic ends, for nothing is ever attained in the world, seeing that the essence of the world—that which holds it together—is strife and change. Pessimism, that is, really denies teleology, as Darwinism does, in the old sense of the term.

(2) In the case of the individual life there is excess of unhappiness and pain over happiness and pleasure. But there is no reason for despising the realisation of certain ends because there always arises a limitless number of new ends to be realised: of course we do not wish to limit the world process. Pessimism thus really comes to stake its case on the individual, which (let us say) to a certain extent we do immediately know. The natural man wants to fill infinity, to gratify all his desires, to embrace in himself all the ends of the world, and because he cannot do this, but even fails to get immediate ends gratified, he votes the world execrable. The pessimists in the end do not escape the all-embracing human standpoint of anthropomorphism, anxious though Schopenhauer is to avoid the errors of metaphysicians and 'transcendental idealism.' They examine man, and what they find to be true of man they predicate of the world: he 'measures' all things—is the microcosm. Still, we must concede that, if to man the world brings only illusion, it is a failure—for him. The central position, then, of pessimism inevitably comes to be that living beings have as matter of fact an excess of pain over pleasure.

To this position the psychologist answers: (1) That pleasure and pain are not things that can be balanced one against the other. Both are *degrees of feeling*, which, though itself a constant element of experience, is only one element; and what we do as matter of fact measure and are conscious of is the amount of change or transition in our feeling, there being of course no absolute measure of amount of pleasurable or painful feeling. (2) Even if by the help of memory and calculation, and observation and reflection (for there is really enormous difficulty in the matter), we allow ourselves to think of sums of pleasures and sums of pains (these are writers who say the phrases are the purest nonsense), yet no one standard of pleasurable or painfulness, no 'hedonistic calculus' or universal method of measuring pain against pleasure, can be fixed upon. (3) Even supposing we had an estimate of pleasures and pains, it is not psychologically legitimate to regard feeling of any kind as the *end* of action; it is only its relative and individual index or measure (i.e. whether normal or abnormal), while there are absolute measures of action in the ends or things accomplished. (4) There are actions which have a final value apart from their pleasurable character, although also as matter of fact the attainment of ends brings (as *accompaniment* and not as *end*) a feeling of immediate pleasure—e.g. the adaptation of the eye to a pleasing object or healthy muscular exercise in general. Schopenhauer went so far as to say that pleasure is only the absence of pain, pain alone being the positive and preponderating element in a sensitive consciousness. This is simply not true: pleasure—if we take the liberty of talking of pleasure as a thing—is as positive as pain is, and the strife which exists in all life is not necessarily painful.

If we ask the pessimist if there is any freedom or release from the 'bondage of man,' we are answered: (1) The light which the Unconscious Will has kindled for itself in the brain of man (pessimism has of course a pronouncedly naturalistic side) confers on us at least one advantage; employing this light, we may for brief moments pause, and survey with pity the awful slavery and strife of life. In a word, artistic perception, the insight into things of the man of genius, of the emancipated intellect, is freedom: art, asceticism, quietistic sympathy, is each the oasis and salvation in the howling wilderness of life. (2) While individual suicide is to be deprecated as the acme of the selfish assertion of the Will to be happy, it is to be hoped

that some day the human race will be educated enough to see the contemptible character of life, and, by a united act of enlightened will, will shake off life and throw the world back into its primeval state of innocence, ignorance, and mere potentiality, and thus become the 'saviour' of the world. There is a basis of moral perception in all this, but it is fantastical: it is the exaggerated statement of the intellectual conditions of salvation often stated in philosophy, as in Aristotle's 'life of contemplation,' the gods of Epicurus, and Spinoza's view of things 'in the light of eternity.' If we demur that it is, then, only the few who can be saved, we are told that the lot of life is one; my life is the same as that in the plant or the planet, and there is, as matters at present stand, not the least fear that the 'will to live' will die out with the death of my life in quietism, agnosticism, and mysticism.

To the metaphysic of pessimism we may also say: (1) That it is not necessary to have a theory of the world in order to make action possible: no one lives because he chooses to live, but because he must, and this apart from the question whether a theory of life is attainable or already attained. (2) That the value of life cannot be measured altogether by the expectations or equations of the individual as to his own happiness, and that therefore pessimism is overthrown with the rejection of ethical hedonism or the theory of ethical conduct that makes happiness the end of life. (3) Pessimism has done good in showing up the illusions to which an acceptance of the Hedonistic or the Epicurean ethic leads in theory and practice; it might be held in fact to give a negative account of man's perfection as consisting not in happiness for happiness's sake, but in the pursuit of ends which are absolutely real, apart from man's desire or aversion to them: to the self-seeking self everything is foreign and negative, and also to the perfection-seeking self the ends of appetite and desire are illusory. The various forms of pessimism—the practical, the biological, the sociological, the poetical, are all of value as provisional accounts of the ethical end. The unconditional sympathy with all forms of life inculcated in modern pessimism is a valuable contribution to ethical theory and history, although of course it is not exactly original to pessimism. (4) The world which Schopenhauer and Hartmann theoretically conceive of is a world which baffles the individual, because in the first instance it appears to them that the world is incomprehensible. Both, in fact, tend to erect our ignorance of the world into a positive principle: the Unconscious; but this is an old metaphysical fallacy. The world which the individual does know—i.e. the small sphere of it he knows—is not a sphere in which he cannot realise himself, but in Kantian language a moral kingdom; it will baffle him if he is only bent on his own happiness. Thus it has been indicated how in a sense the pessimists are not to be held down to an Epicurean theory of morals, although they take their start from that.

BIBLIOGRAPHY.—Schopenhauer's chief work is the *World as Will and Idea* (Eng. trans. 3 vols. 1883-86). His ethic is contained chiefly in the fourth book, on the *Assertion and Denial of the Will to Live*. The appendices contain many exceedingly readable and lucid presentations of the main points of his system, and so do many of the sections of the *Parerga und Paralipomena*, which have a high literary value. See translations of these in T. E. Sanders's 'Schopenhauer' series (1890 et seq.). Hartmann's views are expounded in *Philosophy of the Unconscious*, which is also translated into English (1884). An admirable short account of his system for the laic mind is that of Dr A. Drews (*Ed. v. Hartmann's Philosophie*, 1890). E. Wallace's account of pessimism in the *Westminster Review* (1876) is eminently instructive, and has chief reference to Hartmann. An introductory

treatise is also that of A. Taubert, *Der Pessimismus und seine Gegner* (1873). Sully's *Pessimism* (1877) is an admirable and careful psychological criticism of pessimism, and contains a good historical sketch. In it there is a list of pessimistic literature. As an introduction to pessimism some account of Leibniz's philosophy ought to be read, and after it Voltaire's vigorous and drastic criticism of the same in *Candide*; the latter will help one to understand what Schopenhauer meant when he called optimism a 'wicked and otiose shallow philosophy.' The religious aspect of pessimism is touched on in an essay in Seth and Haldane's *Essays in Philosophical Criticism* (1883), and also in Professor Tulloch's *Modern Theories* (1884).

PESTALOZZI, JOHANN HEINRICH, educational theorist, was born at Zurich, 12th January 1746. Eccentric, quixotic, eager to be an adjuster of social wrongs from his youth, he sought to realise his aims through educating the young. He shares with Rousseau, whose *Emile* greatly influenced his mind, the honour of conceiving a method which is the corner-stone of all sound theories of primary education. From his day onward two ideas of education co-existed—the older one, applicable to the children of the classes; his, applicable to the children of the masses; the former being in many ways improved by an encroachment of the latter upon its traditional domain. Pestalozzi, living during the period of the French Revolution and the wars of Napoleon, found in his disturbed country, in the misery inflicted by war, opportunity for the display of self-sacrifice, devotion to the oppressed, and that unselfish love of the children of the very poor which especially distinguished him. Illiterate, ill dressed, a bad speaker, and a bad manager, Pestalozzi was unfit for the everyday business of life, and all his undertakings resulted in practical failure, though rousing the admiration of Europe, and calling forth down to the present day in many countries, more especially in Germany, a crowd of disciples, who have carried out the principles of their master with great enthusiasm. Although he was totally unable to cope with the world, Pestalozzi's personality was instinct with a loving sensibility; he awoke men to a sense of responsibility to childhood, and ushered the 19th century upon the stage of history as the educational age *par excellence*.

His life is soon told. Believing justly in the moralising virtue of agricultural occupations and rural environment, he chose a farm upon which to dwell with his collected waifs and strays as a father among his own. The farm Neuhof, in the canton Aargau, stranded on a faulty domestic economy after a five years' struggle (1780). Pestalozzi withdrew then from practical life, to think out the educational problem. His *Evening Hours of a Hermit* was the first fruit of his meditations, and develops the following thoughts: before undertaking to educate man, learn to know him; the method whereby to educate man should be founded upon his own nature; in his nature are hidden the forces that draw out his faculties, exercise them; exercise, the instrument of education, connects the wants of our nature with the objects that satisfy them; to rejoice in the fullness of your strength, make your education answer to your needs and to the inner call of your soul. Then came a social novel, *Leonard and Gertrude*, in four volumes. The former is a drunken stone-mason, the latter his wife, and a good one; the scene, a village given over to corruption. At last the minister, the schoolmaster, Gertrude with a few peasant-women, set about the reform of the village. This story created much attention, and was followed by a long period of literary activity on the part of its author. In 1798 he plunged into action again by opening his orphan school at Stanz. The picture he there makes of a moneyless, helpless, homeless lover of children,

gathering homeless, helpless children around him in an old convent in a township ruined by war, and set upon by a hostile and ignorant peasantry, is a noble and pathetic picture. But times and men proved too hard for Pestalozzi. At the end of eight months this establishment was broken up.

He next wended his steps to the people's school at Berthoud (Burgdorf), in canton Bern, only to be ejected from his subordinate position there, at the age of fifty-five, by the jealous and bigoted senior master. He knew then the bitterest pangs of poverty, and had even to keep away from church for want of clothes. In partnership with others, and under the patronage of the Swiss government, he opened an experimental school of his own at Berthoud. While there he published *Hans Gertrude Educates her Children*. Germany greedily devoured the book. It is the recognised exposition of the Pestalozzian method, and sets forth that the development of human nature should be in dependence upon natural laws, with which it is the business of every good education to comply; in order to establish a good teaching method, learn first to understand nature, its general processes in man, and its particular processes in each individual; observation, the result of which is a spontaneous perception (intuition) of things, is the method by which all objects of knowledge are brought home to us. This last affirmation, containing in essence the whole theory of so-called *intuitive* education, is the corner-stone of the German Volksschule ('folk-school'), the guiding principle of numberless books written for children, and the subject of numberless treatises on education.

In 1805 Pestalozzi moved his school to Yverdon, which here drew upon him the eyes of all Europe; in spite, however, of this his greatest moment of popularity and promise of worldly success, he entered upon a course of mistakes that led him to the grave, a disappointed and unsuccessful man. Deviating from the field of primary teaching, he applied his method in a large secondary school for the sons of notable Europeans attracted by his fame. His old incapacity in practical affairs brought the school down step by step till it was closed in 1825, and Pestalozzi, aged eighty, distracted by the enmity of some of his former colleagues, sinking under difficulties of his own making, an object of mingled pity and respect, addressed to mankind the *Song of the Swan*, a last educational prayer, and withdrew to Brugg (Aargau), where he died, 17th February 1827. Pestalozzi's books are all written in German.

See Pestalozzi's *Educational Writings*, ed. Green and Collie (1912); also the article 'Pestalozzi' in *Quick's Essays* (1890); Morf, *Zur Biographie Pestalozzi's* (4 vols. 1864-89); De Guimp's monograph, translated by John Russell (1890); Kussi's *Pestalozzi* (New York, 1895); *Leonard and Gertrude* (Eng. trans. 1825); J. Guillaume, *Pestalozzi, Etude Biographique* (1890); Green, *Pestalozzi, his Life and Work* (1913).

Pétain, HENRI PHILIPPE OMER, French marshal, was born at Cauchy la Tour (Pas-de-Calais) 24th April 1856. A colonel in 1914, he took command of the Second Army in June 1915. From February 1916 he organised the defence of Verdun, and in May he took command of the armies of the north and north-east. He was made a marshal in November 1918.

Petal. See FLOWER.

Petard, an instrument for blowing open the gates of a fortress, demolishing palisades, &c., consisting of a half-cone of thick iron filled with powder and ball; this was firmly fastened to a plank, and

the latter was provided with hooks to allow of its being attached securely to a gate, &c. The petard, which was lighted by a slow match, was superseded by the use of powder-bags. See BOMB, and SHELL.

Petasites. See BUTTERBUR.

Petavius, DIONYSIUS, the name by which the great Catholic theologian Denys Petan is usually known. Born at Orleans, 21st August 1583, he studied at Orleans and Paris, became a teacher in the university of Bourges in 1602, in 1605 entered the order of Jesuits, and 1621 was made professor of Theology in the university of Paris. This post he held for twenty-two years, but in 1646 he retired and devoted himself to the completion of a remarkable series of works in philology, history, and theology. Of his 49 works among the best known are editions of Synesius (1611) and Epiphanius (1622); *De Doctrina Temporum* (1627); *Tabula Chronologica* (1628); *Rationarium Temporum*, an outline of universal history (1634); and *De Theologicis Dogmatibus*, a history of doctrines (1644-50; new ed. by Thomas, 8 vols. 1864 *et seq.*); besides polemical works against Grotius and Salmasius. He died in Paris, 11th December 1652.

Petchenga. See PETSAMO.

Petchora, a large river of Russia, rises on the western slope of the Urals, flows north through the eastern parts of the governments of Vologda and Archangel, then south-west for 150 miles, and finally sweeping northwards into an estuary 30 miles wide and full of islands, falls into the Arctic Ocean, after a course of 975 miles. It is navigable by boats for upwards of 700 miles. The country through which the river flows is thinly peopled and quite uncultivated; dense forests extend on both sides, and the character of the scenery is large, sombre, and melancholy. See Schobin's *Siberia in Europe* (1881).

Petechia. This term is given to spots of a dusky crimson or purple colour, quite flat, with a well-defined margin, and unaffected by pressure, which closely resemble flea-bites. These spots result from a minute extravasation of blood beneath the cuticle. They occur most frequently on the back, at the bend of the elbow, and in the groin. They indicate an altered state of the blood, and are characteristic of the disease called *purpura*; but are often symptoms of very serious diseases, as of typhus fever, plague, senility, &c. They likewise occur in very severe cases of smallpox, measles, and scarlet fever, when their presence must be regarded as indicative of extreme danger.

Peter, ST, the disciple and apostle of Jesus Christ, originally bore the name of Simon or Symeon, Peter being the Greek form of the name bestowed upon him by Christ ('Cephas = rock or stone'). His father's name was John, and he was the brother of Andrew. He was married and lived in Capernaum. His occupation was that of a fisherman. He was first of all a disciple of John the Baptist, and subsequently responded to the call of Christ. He became a leader of the band of disciples, and played a prominent part in the gospel narrative. It was he who was the first to recognise the real character of Christ and to make the great confession, 'Thou art the Christ, the son of the living God.' Just before the Crucifixion he was guilty of a great act of disloyalty in denying his master. According to the account given by Paul in 1 Cor. xv., it was to Peter that Christ appeared first of all after the Crucifixion. Peter became one of the first champions of the Christian faith in Jerusalem. In Acts we find him acting as spokesman of the rest on the day of Pentecost and afterwards. It was he who,

pronounced sentences on Ananias and Sapphira, and together with John visited the converts in Samaria. He was the first to recognise the right of the Gentiles to a place in the Christian Church. He took a prominent part in the Council of Jerusalem, and subsequently went to Antioch, where he had a serious dispute with Paul on the question of the relations between Jewish and Christian converts. At this time our definite information ends, and the rest of Peter's life is obscure. We are entitled to deduce from the opening verses of 1 Peter (and the deduction seems to be valid whether we accept or reject the Petrine authorship of the epistle) that his missionary activity extended through the five provinces of Asia Minor, and if we take the reference to Babylon literally in 1 Peter 5-13 we should be driven to the conclusion that he also laboured in the far east. It is much more probable, however, that Babylon is used in this passage as in the Apocalypse to denote Rome. Whether Peter had any connection with Rome or not has always been a subject of controversy between Catholicism and Protestantism. The Catholic Church has always maintained that he was the first bishop of Rome, and therefore the founder of the papacy, and that his episcopate lasted from 42 to 67 A.D. The evidence has in recent years been re-examined by Sir W. Ramsay and others, and the conclusion which is now generally accepted seems to be this. There is sufficient testimony to make it extremely probable that Peter visited the Roman Church, that he was associated with Paul in the work, and that the two apostles suffered martyrdom in the city, but there is absolutely nothing to show that Peter was ever bishop in the technical sense of the term, and it is entirely contrary to the facts to suppose that he lived in Rome for twenty-five years. The grounds on which this conclusion is reached may be summarised as follows: (a) The references in Clement of Rome and in Ignatius seem to imply that both Peter and Paul were known to the Roman Church; (b) Dionysius of Corinth (c. 171 A.D.) attributes the origin of the Roman Church to the work of the two apostles, and his statement is supported by Irenaeus (180); (c) Tertullian and Cyprian of Rome definitely speak of the 'double martyrdom' of the two apostles; (d) the first definite reference to Peter's episcopate is found in Eusebius (325), and is far too late to be of any value.

The fact of Peter's martyrdom seems to be well authenticated. (1) It is implied in the Gospel of John xxi. 18-19, and (2) definite evidence from at any rate the year 200 is found in the writings of the Fathers. Eusebius preserves a tradition that he was impaled or crucified with his head downward. The date usually assigned to this event is the year 67 A.D., but Sir W. Ramsay has recently advocated a theory that Peter lived till after the year 80. The basis of this theory is as follows. Sir W. Ramsay is convinced that Peter wrote the first epistle which is attributed to him, but he is equally certain that the epistle could not have been composed till the time of Domitian, because the facts which it gives with regard to the persecution prove that it is referring to the Domitianic persecution. The only way of reconciling these two positions is to prolong Peter's life beyond the traditional date. The theory, however, has not as yet won many converts. In later times (in addition to our two canonical epistles of Peter) a whole literature was ascribed to the apostle. The most interesting of these books are the 'Gospel of Peter' and the 'Apocalypse of Peter,' fragments of which were discovered at Akhmim in Egypt in 1886, and subsequently edited by Robinson and James (1892). Other writings ascribed to the apostle include the 'Acts of Peter,' 'The Preaching

of Peter,' and 'The Journeys of Peter'—all of which are, of course, apocryphal.

There is no standard Life of Peter, but the best modern treatment of his career is to be found in Chase's article in *Hastings's Bible Dictionary*. See also H. A. Birks, *Studies in the Life and Character of St. Peter* (1887), and Conard, *Simon Petrus der Apostel des Herrn*. On the relations between Peter and Rome, see Ramsay, *The Church and the Roman Empire*; Lightfoot, *Apostolic Fathers*, Clement II., pp. 481 ff.; Sanday and Headlam, *Romans*, pp. xxvii. f.; Littledale, *Petrine Claims* (1889). The most important modern books on the Catholic side are Alliez, *St. Peter* (2d ed. 1871); Dollinger, *First Age of the Church* (3d Eng. ed. 1877); and Johann Schmid, *Petrus in Rom*. For the apocryphal literature attributed to Peter see Lipsius, *Die apokryphen Apostelgeschichten und Apostellegenden* (1893-1900), and Tischendorf's text of the Acts of Peter and Paul.

PETER, THE EPISTLES OF, two of the Catholic Epistles in the New Testament. The first epistle is by far the best authenticated. It was accepted as canonical without any question from the earliest times. It was written to the churches of the five provinces of Asia Minor, to encourage them to be steadfast in a time of 'fiery persecution.' Unvarying tradition ascribes the authorship of the epistle to Peter, but modern criticism has raised some objections to this position on the following grounds: (a) the data connected with the persecution belong to the age of Domitian; (b) the epistle is written in such a pure Greek style that it could not have been the work of one who is described in Acts as an 'ignorant and unlearned' man; (c) it has so many affinities with Pauline thought that it could only have been written by a disciple of Paul; (d) it is difficult to explain the complete absence of references to the life and teaching of Jesus if the epistle were the composition of one of his most intimate disciples. In order to meet these difficulties several suggestions have been made. (1) Zahn thinks that though the substance of the epistle came from Peter, the composition and diction are due to Silas, who was entrusted by the apostle with the task of putting his ideas into shape for the Asiatic churches. (2) Von Soden thinks that the epistle was written by Silas, who used Peter's name to give greater weight to his own words. (3) Harnack maintains that the opening and closing paragraphs of the epistle are a later addition, and that the main body of the letter was written by some prominent Roman teacher who was a disciple of St. Paul. The objections which have been raised against the Petrine authorship, however, are none of them unanswerable, and are nothing like as serious as the difficulties raised by the modern theories. On the whole the balance of probability and the weight of modern scholarship are on the side of the traditional view. There is much diversity of opinion with regard to the date of the epistle. Renan and Zahn date it before the Neronian persecution, between 59 and 63. Hort, Lightfoot, and most English scholars put it immediately after the Neronian persecution, between 65 and 70; Swete and Ramsay date it between 70 and 80; Harnack (with some hesitation in favour of an earlier date), Von Soden and McGiffert between 81 and 96. The most unique feature of the epistle is the reference to the preaching of Jesus to the dead in Hades, ch. iii. 19-22.

The second epistle stands on a different footing altogether. There is more doubt about its authenticity and canonicity than there is in the case of any other book in the New Testament. The epistle makes claims for itself which it is very difficult to substantiate. The external evidence in its favour is very weak. There is no clear trace of its existence till the time of Origen. There is no reference to it in the Muratorian Canon, or in

the writings of Tertullian and Cyprian. Eusebius regarded it as one of the disputed books, and says that the balance of evidence is against its admission to the canon, though he is willing to admit that it might be used with spiritual profit. The absence of the epistle from the old Syriac version is an additional reason for doubting its claim for recognition. It was not till the 4th century that it secured its place in the New Testament. The doubt is increased when we turn to the internal evidence of the epistle itself. There is a marked contrast between the first and second epistles of Peter. 'The Greek style of the first epistle is simple and natural,' as Chase says, 'without a trace of self-conscious effort. The style of 2 Peter is rhetorical and laboured, marked by a love for striking and startling expressions.' The difference extends also to the subject-matter and theology of the two books. Moreover, there is a close connection between 2 Peter and Jude. The whole of Jude has been incorporated in 2 Peter, and modern scholarship has decided that on the whole Jude seems the more original and primary of the two documents. There are points of contact between 2 Peter and the newly-discovered fragments of the apocryphal 'Gospel of Peter,' and 'Apocryphus of Peter,' though it is difficult to say in this case which is the earlier writing. Dr Sanday reaches the following conclusion: 'It is no doubt possible that the writer of the Apocryphus may have imitated the epistle, or that both may have been affected by some common influence. If there had been, on the whole, better reason than not for believing the epistle to be the genuine work of Peter, it would be natural to fall back on some such assumption. But as the balance of argument is really the other way, it is on the whole more probable that the two writings (i.e. the Apocryphus and the 2d Epistle) are by the same hand. In spite of these arguments the epistle has some important supporters, and its genuineness has been defended in recent times by Zahn, Spitta, and Bigg. On the other hand, scholars like Harnack, Sanday, Ramsay, and Moffatt hold that the epistle was not written till towards the middle of the 2d century.'

The best commentaries on the first epistle are by Maisterman, Knopf, Gunkel, Bigg (*International Critical*), Bennett (*Century Bible*); and on the second epistle Mayor, Bigg, Von Soden, Knopf, Spitta, and Bennett. See also the articles by Chase in *Hastings's Bible Dictionary*; Holson, *Studies in the Second Epistle of St Peter*; O. D. Foster, *The Literary Relations of 1 Peter*. Leighton's *Practical Commentary on 1 Peter* is full of useful suggestions.

Peter the Cruel. See PEDRO.

Peter the Great. Peter I., Alexandrovich, emperor of Russia, was the son of the Tsar Alexei by his second wife, Natalia Narishkina, and was born at Moscow, 11th June 1672. His father died in 1676, leaving the throne to his eldest son, Feodor, Peter's half-brother. This prince, however, died in 1682 without issue, after naming Peter as his successor, to the exclusion of his own full brother, Ivan, who was weak-minded. This step immediately provoked an insurrection of the 'streltzi' or militia, fomented by Ivan's sister, the grand-duchess Sophia, who, after a campaign of three days, succeeded in obtaining the coronation (July 1682) of Ivan and Peter as joint rulers, and her own appointment as regent. Up to Peter's coronation his education had been greatly neglected, but after this time he had the good fortune to fall under the guidance of Lefort (q.v.), a Genevese, who initiated him into the sciences and the arts of civilisation, and by showing him how much Muscovy was in these respects behind the rest

of Europe, influenced the whole of his future career. Lefort also formed a small military company out of the young men of noble family who attended Peter, and he rendered the tsar himself all the while amenable to strict discipline. This course of training in all probability saved Peter from becoming the mere savage despot which his brutal and passionate disposition and indomitable energy inclined him to be; it also protected him from the jealousy of his half-sister, the regent Sophia, who thought him absorbed in military exercises, studies, and amusements. She, however, soon discovered her error, for Peter, contrary to her wishes, married (1689), by his mother's advice, Eudoxia Feodorovna Lopukhin; and in October of the same year called upon his sister to resign the government. In the ensuing contest Peter was at first worsted, and compelled to flee for his life; but he was joined by the foreigners in the Russian service, with Patrick Gordon (q.v.) and Lefort at their head; and the streltzi flocking to his standard, Sophia resigned the contest, and was shut up in a convent, whence, till her death in 1704, she did not cease to annoy him by her intrigues. On October 11, 1689, Peter made his public entry into Moscow, where he was met by Ivan, to whom he gave the nominal supremacy and precedence, reserving the sole exercise of power for himself. Ivan only enjoyed his puppet sovereignty till 1696.

Peter's first care on assuming the government was to form an army disciplined according to European tactics, in which labour he was greatly aided by Gordon and Lefort, both of whom were military men. He also laboured to create a navy, both armed and mercantile; but at this period Russia presented few facilities for such an attempt, for she was shut out from the Baltic by Sweden and Poland, and from the Black Sea by Turkey, leaving only the White Sea and the Arctic Ocean, with the solitary port of Archangel, available for the Russian navy. Peter, thinking the possession of a portion of the Black Sea would best supply the required facilities of accessible seaboard and port, declared war against Turkey, and took (1696) the city of Azov at the mouth of the Don, after a long siege. Skilled engineers, architects, and artillerymen were now invited from Austria, Venice, Prussia, and Holland; ships were constructed, and the army further improved both in arms and discipline. Many of the young nobility were ordered to travel in foreign countries, chiefly in Holland and Italy, and to take special notice of all matters in connection with shipbuilding and naval equipments; others were sent to Germany to study the military art. Peter was eager to see for himself the countries for which civilisation had done so much; and, after repressing a revolt of the streltzi and dispersing them among the various provinces, he left Russia in April 1697, in the train of an embassy of which Lefort was the head. In the guise of an inferior official of the embassy he visited the Baltic seaboard, Prussia, and Hanover, reaching Amsterdam, where, and subsequently at Zaandam, he worked for some time as a common shipwright; and to his practice of shipbuilding and kindred trades he added the study of astronomy, natural philosophy, geography, and even anatomy and surgery. On receipt of an invitation from William III. he visited England, and for three months, spent partly in London and partly at Deptford, laboured to amass all sorts of useful information. While in England he received the honorary degree of D.C.L. from the university of Oxford. He left England in April 1698, carrying with him English engineers, artificers, surgeons, artisans, artillerymen, &c., to the number of 500, and next visited Vienna, for the purpose of inspecting the emperor of Austria's army, then the

best in Europe. He was about to visit Venice also, when the news of a formidable rebellion of the streltzi recalled him to Russia. General Gordon had already crushed the revolt, and Peter finally broke up the institution that had given him so much trouble. The Empress Endoxia, who was suspected of complicity in the conspiracy, which had been the work of the old Russian or anti-reform party, was divorced and shut up in a convent, and the great reforms were begun. Peter put the press on a proper footing, caused translations of the most celebrated works of foreign authors to be made and published, and established naval and other schools. Ordinary arithmetic was first introduced, accounts having been previously kept by means of the Abacus (q.v.). Trade with foreign countries, which was formerly punished as a capital crime, was now permitted, or rather, in the case of the principal merchants, insisted upon. Many changes in dress, manners, and etiquette were introduced and enforced on the people at large. Even the organisation of the national church could not escape Peter's reforming zeal.

In 1700 Peter, desirous of gaining possession of Karelia and Ingria, provinces of Sweden which had formerly belonged to Russia, entered into an alliance with the kings of Poland and Denmark to make a combined attack on Sweden; but he was shamefully defeated at Naava, his war troops being wholly unable to cope with the Swedish veterans. Peter was by no means disheartened, but quietly appropriated a portion of Ingria, in which he laid the foundation of the new capital, St. Petersburg, 27th May 1703. Great indentments were held out to those who would reside in it, and in a few years it became the Russian commercial depot for the Baltic. In the long contest with Sweden the Russians were almost always defeated; but Peter saw that these reverses were administering to his troops a more lasting and effective discipline than he could have hoped to give them in any other way. He had his revenge at last, in totally routing the Swedish king, Charles XII., at Poltava (q.v.), 8th July 1709, and in seizing the whole of the Baltic provinces and a portion of Finland in the following year. His success against Sweden helped much to consolidate his empire and to render his subjects more favourably disposed towards the new order of things. After reorganising his army he prepared for strife with the Turks, who, at the instigation of Charles XII. (then residing at Bender), had declared war against him (see TURKEY). In this contest Peter was reduced to such straits that he despaired of escape. But, according to a somewhat doubtful tradition, the finesse and ability of his mistress, Catharine, extricated him from his difficulties; and a treaty was concluded (1711) by which Peter lost only his previous conquest—the port of Azov and the territory belonging to it. He was thus shut out from the Black Sea, so the possession of a good seaboard on the Baltic became the more necessary to him, and the war against Sweden in Pomerania was accordingly pushed on with the utmost vigour. In 1712 his marriage with his mistress, Catharine (see CATHARINE I.), was celebrated at St. Petersburg, and the offices of the central government were transferred to the new capital. His arms in Pomerania and Finland were victorious, and in 1713 the latter province was completely subdued. In 1716 17, in company with the empress, he made another tour of Europe, this time visiting Paris, and returned to Russia in October 1717, carrying with him quantities of books, paintings, statues, &c. It was soon after this time that his son Alexei (q.v.), who had opposed some of his father's reforms, was condemned to death, and died in prison—apparently

through having been repeatedly tortured. Many of the nobles who had been implicated in his treasonable plans were punished with savage barbarity. In 1721 peace was made with Sweden, which definitely ceded the Baltic provinces, Ingria, and part of Finland, with the islands off the coasts. In 1722 Peter commenced a war with Persia, in order to open up the Caspian Sea to Russian commerce, and secured three Caspian provinces along with the towns of Derbend and Baku. For the last years of his life he was chiefly engaged in beautifying and improving his new capital and carrying out plans for the more general diffusion of knowledge and education among his subjects. In the autumn of 1724 he was seized with a serious illness, and he died 8th February (28th January o.s.) 1725. Catharine succeeded him. The 'Testament of Peter the Great,' inciting the Russians to aim at domination in Europe, is a forgery, based probably on Lesur's *Progrès de la Puissance Russe* (1807), and, it may be, inspired by Napoleon.

See Russian Lives by Golikov (30 vols. 1797) and Ustrajlov (1863); English Lives by Barrow (new. ed. 1883) and Schuyler (2 vols. 1884); and for a vindication of the authenticity of the 'Testament,' W. J. Thoms in the *Nineteenth Century* (1878).

Peter II. (ALEXEIJEVICH) of Russia, was the sole male representative of Peter the Great, being the son of the unfortunate Alexei (see above), and was born 23d October 1715 at St. Petersburg. On the death of the Empress Catharine I. he ascended the throne (1727). Menschikoff, his guardian, affianced one of his daughters to the youthful tsar, but his power was overthrown by the Dolgoruki family. The tsar was seized with smallpox, and died at St. Petersburg, 29th January 1730.

Peter III. (FEODOROVICH) of Russia, grand son of Peter the Great (being the son of his eldest daughter Anna Petrovna, wife of the Duke of Holstein-Gottorp), was born at Kiel, 20th January 1742, and in 1742 was declared by the Empress Elizabeth (q.v.) her successor on the throne of Russia. From the time of his being publicly proclaimed heir he lived at the Russian court; and in obedience to the wishes of the empress he married Sophia Augusta, a princess of Anhalt-Zeitz, who on entering the Greek Church assumed the name of Catharina Alexievna. Peter succeeded Elizabeth on her death in 1762; and his first act of authority was to restore East Prussia to Frederick the Great (whom he admired extravagantly), and to send to his aid a force of 15,000 men. He also recalled many of the political exiles from Siberia. When arranging in 1762 a campaign to take Sleswick from Denmark a formidable conspiracy, headed by his wife, and supported by the principal nobles, broke out against him—a conspiracy which originated in the general discontent at the tsar's liberal innovations, the preference he showed for Germans, his indifference to the national religion, and his servility to Frederick the Great. The tsar was declared to have forfeited his crown; his wife Catharine was proclaimed as Catharine II. (q.v.); and Peter, who supinely abdicated, was strangled by Orloff and some of the conspirators on the 17th July 1762. See Nisbet Bain, *Peter III.* (1902).

Peterborough. a city in the administrative county of the Soke of Peterborough, generally reckoned as part of Northamptonshire, on the river Nen, at the edge of the fen-country, 76 miles N. of London and 42 N.E. of Northampton. Here, at Medeshamsted, in 655, the Mercian thane Saxon founded the great Benedictine abbey of SS. Peter, Paul, and Andrew, which, destroyed by the Danes in 870, was restored in 966, plundered by Hereward in 1069, and again burned down in 1116. Its noble church, the cathedral since 1541 of a new diocese

carved out of that of Lincoln, was built between 1118 and 1528, and thus, whilst essentially Norman, offers every variety of architecture down to the Perpendicular. It is 471 feet long, by 202 across the transept, and 81 high. The Early English

city governors. In 1790 a new administrative body, known as the Peterborough Improvement Commissioners, was established. This was replaced by the Peterborough Corporation when the city was incorporated as a municipal borough in 1874. The citizens of Peterborough returned two members to parliament from 1547 till 1885, and thereafter one, but since 1918 the borough constituency has been merged in the Peterborough parliamentary division of Northamptonshire. The corporation are the undertakers for the supply of electricity in an extensive area surrounding the city. Pop. (1841) 6959; (1881) 22,394; (1901) 30,872; (1921) 35,533.—The administrative county of the Soke of Peterborough was created under the provisions of the Local Government Act of 1888, being a survival of the soke of the abbey. Over this area the Marquess of Exeter is lord paramount, and nominates the justices for the liberty of Peterborough, who exercise all the powers of a judge of assize. Area, 84 sq. m.; pop. (1921) 46,954.

Peterborough Cathedral—West Front.

west front (c. 1200-22) consists of three mighty arches, and 'is perhaps,' says Freeman, 'the grandest conception for a single feature which mediæval architecture has produced, a Greek portico translated into Gothic language.' Noteworthy also are the flat painted wooden ceilings of the 12th century, the portrait of 'Old Scaletts' the sexton (1496-1594), the blue slab inscribed 'Queen Catharine, A.D. 1536,' and the grave for twenty-five years (1587-1612) of Mary Queen of Scots. In 1643 Cromwell and his troopers did hideous havoc to monuments, stained glass, and cloisters. In 1883 the fine central tower was condemned as unsafe; but it was lovingly rebuilt, and in 1890 the cathedral was reopened after restoration, resumed in 1895. Of the abbots may be mentioned Ernulf, Bishop of Rochester (1115); and of the bishops, Lloyd and White the non-jurors, Richard Cumberland, Archbishop Magee of York, and Mandell Creighton the historian. Paley was a native. Two ancient gateways, the bishop's palace and the deanery (once the abbot's and prior's houses), and the chancel of a Becket chapel make up the remaining objects of interest. A training-college for women (1864), a grammar-school, the town-hall (1671), the corn exchange (1848), a cattle-market of five acres (1867), and the bridge over the Nen (dating from 1140, but in its present form from only 1872) may be mentioned. Peterborough is the centre of a poor-law union, a county court district, and has a probate registry. The city is an important railway centre, has considerable engineering works, and carries on a large trade in malt, coal, farm-produce, &c. The adjoining suburb of old Fletton is the centre of a large pressed brick-making industry. The city was established on 4th September 1541 by letters patent of Henry VIII., and was governed partly by the dean and chapter as lords of the manor and partly by the Peterborough feoffees and

Peterborough, chief town of Peterborough county, Ontario, on the Otanabee River (here crossed by several bridges), 69 miles N.E. of Toronto. It exports lumber, grain, and pork, and manufactures flour, woollens, farming implements, machinery, furniture, canoes, &c. Pop. 21,000.

Peterborough, CHARLES MORDAUNT, EARL OF, was born in or about the year 1658. All particulars of his boyhood, even to the place of his education, seem to have been lost. The first definitely recorded event in his life is his voyage as a volunteer in Sir John Narborough's expedition against the Algerine corsairs in 1674. From this voyage, in which he saw actual service, he returned early in 1677, to find himself in his twentieth year Viscount Mordaunt, his father, John, first peer of that title, which he owed to his services in assisting to bring about the Restoration, having died in 1675. The new viscount shortly afterwards married Carey, daughter of Sir Alexander Fraser, and in 1678 started on another maritime expedition, this time apparently in the capacity of a passenger. Returning after a year's absence, he again volunteered for naval service, and sailed with the fleet sent under Lord Plymouth for the relief of Tangier. On his return to England he began to take an active part in politics, identifying himself with the extreme Whig party throughout the whole of the three or four eventful years which closed with the ruin and flight of Shaftesbury, and the final triumph of the indolent and dissolute but shrewd and able monarch, against whom that restless agitator had pitted himself. At the accession of James II. Mordaunt became a prominent parliamentary opponent of the first unpopular measures of the new king, and one of the earliest intriguers for his overthrow. Indeed he went at once so fast and so far as to press upon William of Orange a premature scheme for the invasion of England, which that prince with his usual cool judgment rejected. After the Revolution, in the military operations connected with which Mordaunt exerted himself vigorously and with success, he rose into high favour with the new king. Honour and emoluments of a varied description, from the post of a privy-councillor to that of

a water-bailiff, were heaped upon him, and he was finally appointed First Commissioner of the Treasury, and created Earl of Monmouth. On William's departure for the campaign in Ireland the new earl was nominated of the committee of nine who formed the Queen's Council of Regency. In the House of Lords he was an extreme and active Whig, but it was probably as much his zealous anxiety to supplant William's ministers suspected of Jacobitism as to combat Jacobite designs themselves that led to his embroilment in those intrigues arising out of the Assassination Plot, and the Fenwick trial, which ultimately resulted (January 1697) in his committal to the Tower. He was liberated in less than three months, and for several years thereafter he seems to have played no prominent part in public affairs.

In 1701 the war of the Spanish succession broke out, and in 1705 Peterborough (for by his uncle's death he had succeeded to that title shortly after his release from imprisonment) was appointed to the command of an army of 4000 Dutch and English soldiers, with which he proceeded to Barcelona, there to begin the extraordinary campaign which has made his name famous in history. After successfully resisting the solicitations to attack the city which were addressed to him by the Prince of Hesse-Darmstadt, fresh from the capture of Gibraltar, and the Archduke Charles, the claimant to the Spanish throne, for whom the allies were fighting, Peterborough succeeded by a pretended retreat in surprising and capturing the strong fort of Monjuich on the south side of Barcelona, from which position of vantage he soon managed to reduce the city. The Catalan towns one after another now declared for Charles; Gerona, Tarragona, Tolosa, and Lerida opened their gates to Peterborough, who, marching southward in the depth of winter and driving his foes before him, reached Valencia early in February 1706. Meanwhile an army under the Duke of Anjou, the French claimant to the throne (afterwards Philip IV.), and Marshal Tessé had entered Catalonia, and was closely investing Barcelona, which was at the same time blockaded by a fleet under the Count of Toulouise. Hurrying back to the scene of his former exploit, and seeing that it was from the side of the sea that the town must be relieved, Peterborough threw himself on board one of the ships of the English squadron, took command in virtue of his commission, which gave him supreme control over the British forces at sea as well as on land, sent his orders to the admiral, and drove Toulouise and his fleet from before the port. This success was followed by the raising of the siege, and the retreat of Tessé's force. Encouraged by the splendid successes of Peterborough on the east coast, Galway, the British commander on the Portuguese frontier, advanced into the heart of Spain, and in June entered Madrid. Peterborough wished to march from Valencia, whither he had now returned, and to effect a junction with Galway, but the archduke dallied irresolutely at Barcelona. Precious time was lost, Berwick rallied his forces, and compelled Galway to evacuate the capital, and when at last Charles advanced and summoned Peterborough to join him, it was too late. A plan formed by him for the recovery of Madrid was rejected, and in disgust he obtained permission to depart for Genoa to raise a loan on the Spanish revenues. Returning with success from his mission, he acted for some time as a sort of adviser to his military successors in Spain, but his imperious temper seems to have unfitted him for anything but supreme command, and his differences with Lord Stanhope and others led to his recall in March 1707.

His career thenceforward till his death at Lisbon

on 25th October 1735 is interesting only to the student of letters and not to the politician. He was, as is well known, an intimate friend of Pope, with whom he was in constant communication almost up to the last day of his life, and whose genuine esteem for him may satisfy us that under the somewhat theatrical exterior which he presented to the world there lay qualities which justly endeared him to his friends. In 1722 he was, it is said, privately married to the famous singer Anastasia Robinson, but the lady was not publicly acknowledged as his countess till shortly before his death. Recent military criticism has made an elaborate endeavour to show that Peterborough's fame as a conqueror rests wholly on a basis of imposture, and that the whole credit of his conquest of Valencia must be distributed among others. This extreme view, however, has been shown by Mr Stebbing in his judicious and impartial monograph to be untenable. His verdict is that 'the figure of the hero remains much where it was, though its pedestal may have been somewhat lowered.'

See the Memoir by Russell (2 vols. 1887), and Stebbing's *Peterborough* ('English Men of Action' series, 1890).

Peterhead, a seaport and burgh of barony of Buchan, Aberdeenshire, on a peninsula, 32 miles by road, but 44 by a branch-line (1862), N.N.E. of Aberdeen. Founded in 1593, it is somewhat irregular in plan, but clean and largely built of the celebrated 'Peterhead granite,' whose reddish variety is much used for monumental purposes. The Keiths, Earls Marischal, were superiors of the place till the rebellion of 1715, when the Old Pretender landed there, after which their forfeited estates were purchased by the Edinburgh Merchant Maiden Hospital, to whose governors many improvements are owing. Of Marshal Keith (q.v.) a bronze statue was presented to the town in 1869 by King William of Prussia; and the market-cross, a granite Tuscan pillar (1833), bears the arms of the Earls Marischal. The public buildings include the town hall (1788), with a spire 125 feet high; the parish church (1803), with one of 118 feet; the free library and museum (1891); the academy (1846); and convict-prison (1889). Industries are woollen manufacture, boat-building, and granite-polishing. Peterhead was made a head-port in 1838. From 1788 it gradually became the chief British seat of the seal and whale fisheries, until in 1852 it sent out 30 ships; but whaling is now extinct. At present Peterhead is chiefly important for its great herring-fishery. The south harbour was begun in 1773, and the north harbour in 1818, a canal being formed between them in 1850; whilst a new harbour was formed under acts of 1873 and 1876, and the south harbour deepened and improved from time to time. Their three basins, hewn out of the solid rock, together cover about 22 acres; but all three are as nothing compared with the great harbour of refuge, designed by Sir John Coode in 1886. The south area has been completed. In the neighbourhood are the ruins of Inverurie, Ravenscraig, and Boddam castles, all strongholds of different branches of the Keiths; Buchan Ness, the most easterly point of Scotland, with a lighthouse (1827); and the Bùlbers of Buchan (q.v.). From 1833 to 1918 Peterhead united with Elgin, &c. to return one member to parliament. Pop. (1801) 3264; (1851) 7298; (1911) 13,613; (1921) 13,003.

Peterhof, a palace of the emperors of Russia, now a museum, on the southern shore of the Gulf of Finland, 18 miles W. of St Petersburg, was built by Peter the Great in 1711, contains a fine collection of paintings, and is surrounded by beautiful parks and gardens laid out on the model of those at Versailles, with cascades, terraces, and

summer-houses. The town of Peterhof has 15,000 inhabitants.

Peter Lombard. See LOMBARD.

Peterloo Massacre, the name popularly given to the dispersal of a large meeting by armed force in St Peter's Field, Manchester, Monday, 16th August 1819. The assemblage, consisting chiefly of bodies of operatives from different parts of Lancashire, was called to consider the question of parliamentary reform, and the chair, on open hustings, was occupied by 'Orator' Hunt (q.v.). The dispersal took place by order of the magistrates; several troops of horse, including the Manchester Yeomanry, being concerned in the affair. Eleven persons (men, women, and children) were killed, and some 600 wounded. St Peter's Field is now the site of the Free-trade Hall. 'Peterloo' was a name suggested by Waterloo. See *Three Accounts of Peterloo*, ed. F. A. Bruton (1921).

Peter Martyr, the patron saint of the Inquisition, a Dominican of Verona, who, for the severity with which he exercised his inquisitorial functions, was in 1252 slain at Como by the infuriated populace. His death formed the subject of a masterpiece by Titian, destroyed by fire at Venice in 1867.

Peter Martyr (Ital. *Pietro Martire Vermigli*), Reformer, was born in Florence, 8th September 1500, entered at sixteen the order of the canons regular of St Augustine at Fiesole, studied at Padua, became abbot of Spoleto, and later prior of St Peter ad Aram near Naples. Here he was drawn into the doctrines of the Reformers by the teaching of Juan Valdes and Ochino, yet was appointed visitor-general of his order in 1541. His rigour made him hateful to the dissolute monks, and he was sent to Lucca as prior of San Frediano, but soon fell under the suspicions of the Inquisition, and had to flee to Zurich (1542). At Strasburg he was welcomed by Bucer, and made professor of the Old Testament. In 1547 he came to England on Crammer's invitation, lectured at Oxford on 1 Corinthians and Romans, and took an active part in the great controversy of the day. Mary's accession drove him back to Strasburg, now too Lutheran for his tastes, and in 1555 he repaired to Zurich, where he died, 12th November 1562. For his *Loci Communes* (printed at London in 1575) see the study by Schmidt (1858), and the article 'Vermigli' in the *Dict. Nat. Biog.*

Peter Martyr Anglerius, historian, was born in 1459 at Arona, on the Lago Maggiore, of an ancient family belonging to Anghera, obtained a footing at the court of Ferdinand and Isabella in 1487, and rose to high ecclesiastical preferment in Spain. He died at Granada in 1525. He wrote *De Orbe Novo* (1516), giving the first account of the discovery of America, and an *Opus Epistolarum* (1530). The *De Orbe*, translated in 1577, and printed by Arber in 1885, was retranslated by MacNutt in 1913. See monograph by Bernays (1890).

Petersburg, a city of Virginia, on the south bank of the Appomattox River, 23 miles by rail S. of Richmond. The falls above supply water-power for foundries, cotton, flour, and paper mills, and especially tobacco factories. Petersburg is a well-built place, and contains a fine park. In the campaign of 1864 Grant, failing to take Richmond, besieged Petersburg, and was repulsed in several attacks by General Beauregard, with heavy loss. Pop. 31,000.

Petersburg. See ST PETERSBURG.

Petersfield, a market-town of Hampshire, 20 miles NNE. of Portsmouth by rail, has a Norman church. Till 1832 it returned two members, till 1885 one. Pop. 4000.

Peter's-pence (*denarius S. Petri*), the name given to a tribute offered to the Roman pontiff in

reverence of the memory of St Peter. From an early period the Roman see had been richly endowed; but the first idea of an annual tribute came from Anglo-Saxon England. It is ascribed by some to Ina (721 A.D.), king of Wessex, by others to Offa of Mercia, and by Lingard to Alfred the Great. It was extended to Ireland by Henry II. The tribute consisted in the payment of a silver penny by every family possessing land or cattle of the yearly value of 30 pence, and it was collected during the five weeks between St Peter's and St Paul's Day and August 1. The tax, also called Rome-scot, varied greatly in amount, but continued to be paid with intervals till the reign of Henry VIII. By Gregory VII. it was sought to establish it for France; and traces of a similar payment appear also in Denmark, Sweden, Norway, and Poland. This tribute differed from the payments of the feudatory kingdoms, such as Naples, Aragon, and England under the reign of John. The tribute practically ceased at the Reformation. The pope having suffered a considerable diminution of his own revenue since the revolution of 1848, an effort was made in several parts of Europe to revive the payment of Peter's-pence, not as a tribute but by the collection of free-will offerings. In some countries it proved very successful; and after the total annexation of the Papal States to the kingdom of Italy the tribute was largely increased in France, Belgium, England, and Ireland. Later it fell off considerably.

Peter the Hermit, a preacher of the first crusade, was of gentle birth, and a native of Amiens, where he was born about the middle of the 11th century. He served some time as a soldier, became a monk, and is usually said to have made a pilgrimage to the Holy Land before 1095, when he joined in the preaching campaign which was to render him famous, and leave such a mark on history. But it should be noted that the scheme of a crusade originated with the pope, not with the hermit, who was only one of many preachers; that his importance has been greatly exaggerated; and that much of his story is legendary. The article *CRUSADES* gives an account of the preaching, its results, and of poor Peter's faint-hearted attempt at desertion during the siege of Antioch. After the end of the crusade he returned to Europe, and founded a monastery at Huy in the Low Countries, where he died, 7th July 1115. His remains were translated to Rome in 1634.

Peter the Wild Boy was found in July 1724 in a wood near Hameln in Hanover; 'he was walking on his hands and feet, climbing up trees like a squirrel, and feeding upon grass and moss of trees.' He was taken to George I., brought over by him to England in 1726, and placed under the care of the celebrated Dr Arbuthnot, who had him baptised 'Peter.' He was fond of music, but could never be taught to articulate more than 'Ki Sho,' 'Qui Ca,' and 'Honi Hen,' for 'King George,' 'Queen Caroline,' and 'Tom Fen'—the last a Hertfordshire farmer with whom he lived after 1737. He would sometimes ramble away, on one occasion as far as Norwich, so was provided with a brass collar inscribed 'Peter the Wild Boy, Broadway Farm, Berkhamstead.' Lord Monboddo visited him in 1782, and in his *Origin of Language* describes him as only 5 feet 3 inches high, now about seventy years of age, quite tame, bearded, and fresh and healthy. But on the farmer's death Peter took to his bed, refused food, and in a few days died, in August 1785. See *Notes and Queries* for 11th October 1884, and works there cited.

Peterwardein (Serb. *Petrovaradin*), now in Yugoslavia, once one of the strongest fortresses in the Hungarian dominions, is situated in a marshy, unhealthy locality on the right bank of the Danube,

opposite Neusatz (Novi Sad). The most ancient part of the defences, the Upper Fortress, is situated on a rock of serpentine, which on three sides rises abruptly from the plain. The fortress was held by the Turks from 1526 to 1687. In 1688 the fortifications were blown up by the imperialists, and the town was soon after burned to the ground by the Turks; but at the peace of Passarowitz (1718) it remained in the possession of the emperor. Here, on 10th August 1716, Prince Eugene obtained a great victory over the Grand Vizier Ali. The Hungarians were compelled to yield the fortress to the Austrians in September 1849.

Petiole. See LEAF.

Pétion de Villeneuve, JÉRÔME, a prominent figure in the French Revolution, was the son of a *procureur* at Chartres, and was born there in 1753. He was practising as an advocate in his native city when he was elected in 1789 its deputy to the *Tiers Etat*. An ardent republican and fluent speaker, he quickly became popular, although essentially windy, verbose, and of mediocre understanding. He was a prominent member of the Jacobin Club, and as 'Pétion the Virtuous' became a great ally of 'Robespierre the Incorruptible.' He was sent along with Barnave and Latour-Maubourg to bring back the fugitive royal family from Varennes, and in the execution of this commission he acted in a brutal and unfeeling manner. He afterwards advocated the deposition of the king, and the appointment of a popularly elected regency, and along with Robespierre received, 30th September 1791, the honors of a civic crown. On the 14th of November he was elected mayor of Paris in Bailly's stead, the court favouring his election to prevent that of Lafayette. The invasion of the Tuileries by the mob and the atrocious September massacres both fell within his year of office. He became the first president of the Convention, and was made ridiculous as 'roi Pétion' through Manuel's proposal to give the president the same authority as the president of the United States. On the triumph of the Terrorists Pétion's popularity declined, and he cast in his lot more and more with the Girondists, having become a *habitué* of Madame Roland's *salon*. Like them he voted at the king's trial for death, but with delay of execution and appeal to the people. He was elected to the first committee of general defence in March 1793, and on 12th April he headed the fatal but unsuccessful attack on Robespierre. Proscribed among the twenty-two, on the 2d of June, he escaped to Caen, and on the failure of the attempt to make armed opposition against the Convention fled to the Gironde with Guallet, Bazot, Barbaroux, Salle, and Louvet, and hid in a grotto at St Emilion. At length they were tracked and obliged to flee. The bodies of Pétion and Bazot were found in a cornfield, partly devoured by wolves. They were supposed to have died by their own hands.

His *Œuvres* fill 3 vols. (1792). See J. J. Regnault-Warin's *hyper-culogistic* life (1792); C. A. Dauban's *Mémoires inédits* (1866); and C. Vatel's *Charlotti Corday et les Girondins* (3 vols. 1872).

Petit de Julleville, LOUIS (1841-1900), born in Paris, wrote an *Histoire du Théâtre en France* and edited a monumental *Histoire de la langue et de la littérature françaises*.

Petition, a supplication preferred to one capable of granting it. The right of the British subject to petition the sovereign or either House of Parliament for the redress of grievances is a fundamental principle of the British constitution, and has been exercised from very early times. The earliest petitions were generally for the redress of private wrongs, and the mode of trying them was judicial rather than legislative. The earlier petitions were generally addressed to the House of

Lords; the practice of petitioning the House of Commons first became frequent in the reign of Henry IV. Since the Revolution of 1688 the practice has been gradually introduced of petitioning parliament, not so much for the redress of specific grievances, as regarding general questions of public policy. Petitions must be in proper form and respectful in language; and there are cases where petitions to the House of Commons will only be received if recommended by the crown, as where an advance of public money, the relinquishment of debts due to the crown, or compensation for losses out of the public funds is prayed for. A petition must, in ordinary cases, be presented by a member of the House to which it is addressed. The system is, however, not without its disadvantages, as when the attempt is made to over-ride the comits of law by popular agitation—vast numbers of petitions being presented on behalf of murderers convicted after fair trial. For election petitions, see PARLIAMENT.

In the United States the right of the people to petition government is expressly secured by the First Amendment of the Constitution, and is thoroughly interwoven with the ideas and usages of the nation—although, during the conflicts on slavery, it was resolved that petitions relating to slavery or the abolition thereof should be laid on the table without being printed or read, and finally that such petitions should not be received at all.

Petition of Right, a declaration of certain rights and privileges of the subject obtained from King Charles I. in his third parliament—the first statutory restriction of the powers of the crown since the accession of the Tudor dynasty. It was so called because the Commons stated their grievances in the form of a petition, refusing to accord the supplies till its prayer was granted. The petition professes to be a mere corroboration and explanation of the ancient constitution of the kingdom; and after reciting various statutes that recognise the rights contended for, prays 'that no man be compelled to make or yield any gift, loan, benevolence, tax, or such like charge, without common consent by act of parliament; that none be called upon to make answer for refusal so to do; that freemen be imprisoned or detained only by the law of the land, or by due process of law, and not by the king's special command, without any charge; that persons be not compelled to receive soldiers and mariners into their houses against the laws and customs of the realm; that commissions for proceeding by martial law be revoked.' The king at first eluded the petition, expressing in general terms his wish that right should be done according to the laws, and that his subjects should have no reason to complain of wrongs or oppressions; but at length, on both Houses of Parliament insisting on a fuller answer, he gave an unqualified assent on the 26th of June 1628. The text of the Petition will be found most conveniently in Gardiner's *Constitutional Documents of the Puritan Revolution, 1628-60* (1889). See also his *History of England*, vi. 274-309.

Petitio Principii ('a begging of the principle or question') is the name given in Logic to that species of vicious reasoning in which the proposition to be proved is itself assumed in the premises of the syllogism.

Petőfi, SANDOR, Hungarian poet, born on 1st January 1823 the son of a butcher, at Kis-Koros, was successively actor, soldier, and literary hack. His first poem, published in 1842, was followed by a volume in 1844 which secured his fame as a poet. He diligently studied German, French, and English, translated Shakespeare's *Coriolanus*, but in 1848 threw himself heartily into the revolutionary cause, writing numerous popular war-songs. He fell in

the battle at Schäss-burg (Segesvár), 31st July 1849; but it was long believed by the Hungarians that he had escaped, and would reappear. His lyrical poetry breaks completely with the old pedantic style, and,

edition appeared in 1873; selections have been translated into English by Bowring and others. There are lives by Opitz (1868) and Fischer (1888).

Petra (the Greek equivalent of the Heb. SELA, both names signifying 'Rock'), anciently the stronghold and treasure-city of the Nabataeans (q.v.), situated in the desert of Edom in north-western Arabia, near the points of intersection of great caravan-routes from Palmyra, Gaza, Egypt, and the Persian Gulf, four days' journey from the Mediterranean and five from the Red Sea. It is approached by a chasm or ravine, which in some places is only 12 feet wide, while the rocky walls of red sandstone tower more than 100 feet above. Along this ravine are the most famous ruin of Petra, the Hazne or 'treasury of Pharaoh,' and a theatre, both shaped out of the solid walls. All along the face of the rocks that overlook the valley are rows of cave-tombs hewn out of the solid stone, and ornamented with façades. The floor of the

Rock Temple at Petra: El Hazne.

valley, about two miles across, is strewn with ruins. The earliest name was, according to some, Rekem; hence Petra has been identified with Kadesh Barnea, and as the place where Moses struck the rock so that water flowed out. The little stream that descends the ravine, flowing eastwards, has its origin in a spring called at the present day the Fountain of Moses. Petra was captured by the Romans in 105 A.D., and thereafter decayed, its place as a commercial centre being taken by Palmyra (q.v.). Nevertheless it continued to exist as a town; most of the remains belong probably to the first century of its decay. From Petra Arabia Petraea gets its name.

See works by Brinnow and Domaszewski (1904), Mühl (1907-8), Dalman (1908), Sir A. Kennedy (1925); and those cited at EDOM.

Petrarch. Francesco Petrarca, one of the earliest and greatest of modern lyric poets, was the son of a Florentine notary, Petracco (diminutive of Peter) di Messer Parenzo. Petrarch's father was exiled from Florence (1302) along with Dante during the struggles between the two factions of the Bianchi and Neri, when the latter party obtained the upper-hand. He took refuge with his family in Arezzo, where, on the 20th July 1304, Francesco was born. The poet's infancy was passed in Tuscany until 1312, when his father determined to go to Avignon, whither the papal court had lately been transferred. There and in the neighbouring small town of Carpentras Petrarch's studies began, and were continued later at Montpellier and Bologna. His father intended him to enter the legal profession; but instead of jurisprudence he devoted himself with enthusiasm to the study of the classics, his favourite authors, on whose style he afterwards strove to model his own, being Cicero and Virgil. It was only later in life that he tried to learn Greek, in which he never attained to any proficiency. After his father's death, whom his mother did not long survive, Petrarch returned to Avignon (1326). As was the custom of the time, more especially at the papal court, he and that brother Gherardo, being without means, became ecclesiastics; but Francesco never took holy orders. His chief source of income became the small benefices conferred on him by his many powerful patrons; but in after-life he refused higher preferment, declining even the much-coveted post of papal secretary, rather than compromise his independence. Petrarch is reported to have been a handsome young man of winning manners, fond of rich clothing and all the refinements of court-life. It was at this period of his life that he first saw Laura, the lady whose name he was to immortalise in his lyrics, and who inspired him with a passion which has become proverbial for its constancy and purity. The meeting took place on April 6, 1327, in the church of St. Clara at Avignon. This date, as well as that of Laura's death on the same day in the year 1348, stands recorded by Petrarch's own hand on the fly-leaf of his Virgil, now amongst the treasures of the Ambrosian Library at Milan. The identity of Laura has been a subject of much discussion, the most generally accepted hypothesis is that of the Abbé de Sade, who identified the poet's love, on somewhat slender evidence, with a member of his own family, Laure de Noves, married in 1325 to a Hugo de Sade; she became the mother of eleven children, and died in April 1348. It was also at this time that Petrarch's friendship began with the powerful Roman family of the Colonnas, and especially with Jacopo Colonna, Bishop of Lombez.

The dawn of the new birth of letters and art which was to illumine the following century was already altering the status of the poet and artist, and as the fame of Petrarch's learning and genius grew his position became one of unprecedented consideration. His presence at their courts was competed for by the most powerful sovereigns of the day, and such was the exceptional position he enjoyed that he has said of himself that princes had lived with him, not he with princes. His chief patrons were Pope Clement VI., the Emperor Charles IV., King Robert of Naples, the Viscounts of Milan, Jacopo da Carrara, Lord of Padua, Azzo da Correggio, Lord of Parma; in Venice the senate bestowed a palace on him in return for his promise to leave that town his library; Florence offered him the restoration of the confiscated possessions of his family if he would reside there, and in Arezzo the house where he was born was held as a sanctuary. When wearied by court-life he sought retirement and quiet in his country-house at Vaucluse, near Avignon. He travelled repeatedly in

France, Germany, and Flanders, wherever he went searching diligently for manuscripts to enrich his collection. He made some valuable bibliographical discoveries, finding in Liège two new orations of Cicero, in Verona a collection of letters of the same writer, and in Florence a then unknown Institution of Quintilian's. In the cosmopolitan society of the papal court Petrarch became acquainted with learned men of all countries, whom he interested in his unwearied search for valuable manuscripts. The example given by Petrarch in his loving preservation of books probably gave the first incentive to the collection of manuscripts which bore such rich fruits in the following century. But the most glorious moment of Petrarch's honored career was when, invited by the senate of Rome on Easter Sunday, 1341, he ascended the capitol clad in the robes of his friend and ardent admirer, Robert of Anjou, king of Naples, and there, after delivering an oration on poetry and the significance of the laurel, he was crowned poet-laureate amid the acclamations of thousands. After this pagan ceremony he went to leave his crown on the altar of St. Peter's. In 1353, after the death of his beloved Laura and his friend Cardinal Colonna, he left Avignon for ever, disgusted with the corruption and vice of the papal court. The remaining years of his brilliant life were passed in various towns of Northern Italy, and in the retirement of a country-house at Arquà, near Padua, the only one of his many habitations still in existence. There, tenderly cared for by his natural daughter, Francesca, and her husband, and occupied to the last in his favourite studies, he quietly ended his life, 18th July 1374.

Petrarch may be considered as the earliest of the great humanists of the Renaissance and the founder of modern classic culture. His passionate admiration for antiquity and the classic authors was no longer that of Dante and the earlier writers, whose erudition was incorporated with the feelings and needs of their own time and stamped with their own individuality. The more contemplative and less original mind of Petrarch lent itself rather to an entire withdrawal from and disdain for all that later times had produced, and his constant effort was to imitate as closely as possible the modes of thought and expression of the great Latin writers. He attained to a surprising purity of style in his Latin works, and the admiration which these writings excited in his contemporaries was boundless. Petrarch himself chiefly founded his claim to posthumous fame on his epic poem *Africa*, the hero of which is Scipio Africanus, and his historical work in prose, *De Viris Illustribus*, a series of biographies of classical celebrities. His other important Latin works are the elegies and epistles in verse; and in prose the dialogues *De Contemptu Mundi* (or the *Secretum*) and the treatises *De Otio Religiosorum* (written while visiting his brother, who had joined a Carthusian brotherhood) and *De Vita Solitaria* (written at Vaucluse); and particularly important for historical and biographical purposes is the numerous collection of letters divided into *Familiares*, *Variae*, *Ad Veteres Illustres*, *Seniles*, and *Sine Titulo*.

Petrarch was an ardent patriot, but he had little practical influence on the political life of his time. His ideas were those of a poet, and not of a statesman. However great his merits as patriot or student, his name would be little remembered now; it is by his lyrics alone that his fame has lasted for six centuries. His title-deeds to fame are in his *Canzoniere*, in the sonnets, madrigals, and songs written in Italian, almost all inspired by his unrequited passion for Laura, in which the character of the man and the reality of a strong sentiment find their expression. The history

of Petrarch's love presents few incidents; its entire interest is psychological. In these poems we see the picture of a human soul in all its contradictions, pains, and struggles. Such self-analysis was unknown in medieval writers, and Petrarch has therefore been called the first modern man. His last work was an allegorical poem in 'terzine,' *I Trionfi* ('Triumphs'), also in Italian, and is of unequal merit, the only remarkable passages being those which refer to the beginning of the poet's love ('Triumph of Love') and to Laura's death ('Triumph of Death'). Few of Petrarch's lyrics treat of other subjects, but amongst these few are three of his finest efforts—one, the famous address to his country (*Italia mia*), in which he reproaches the Italian princes for their dissensions, and for calling to their aid the mercenary 'barbarians' who were the scourge of Italy, words repeated by Machiavelli in his *Prince*, a century and a half later, and in our own day in the struggle for freedom from Austria; the second (*Spirto Gentil*), which some commentators consider to be addressed to the young Colonna, and others to the famous Cola di Rienzi, whose wild attempt to resuscitate the ancient forms of republican government in Rome had fired Petrarch with enthusiasm; and the third (*O Aspettata in Ciel Beata e Bella Anima*), addressed to his friend Jacopo Colonna, to incite him to join the crusade of Philip of France against the infidels. Petrarch was in constant correspondence with his great contemporary, Giovanni Boccaccio (*Lettere di Boccaccio*, ed. by Corazzini, Florence, 1877), and translated into Latin his friend's tale of Patient Griselda (*De Obediencia et Fide Uxoraria*). Chaucer alludes to this when he says of his Clerk's Tale:

Lerned at Padowe of a worthy clerk,
Famous for Petrarch, the laureat poet,
Highte this clerk, whose rethorik was
Enlorned at Baile of poetrye.

The earliest complete edition of Petrarch's works is *Francisci Petrarce Opera Omnia* (Basel, 1554, fol.). His Italian lyrics were published as early as 1470 (Venice, 4to), and have since gone through innumerable editions with or without commentary. Marsand's text (Padua, 1819, 4to) was used by Leopardi for his important edition and commentary (Milan, 1826), often reprinted. The letters have been edited by Fracassetti, and partly translated into Italian, with a valuable commentary (Florence, 1859-63-69). There is a concordance by K. Mackenzie (1912). See the Abbé de Sade, *Mémoires de Pétrarque* (1764); Mézières, *Pétrarque* (1868); Koerting, *Petrarcas Leben und Werke* (1878); the little monograph by Henry Reeve (1878); also Gaspari, *Italianische Literatur* (Berlin, 1885); Bartoli, *Letteratura Italiana* (1884); De Sanctis, *Scoglio sul Petrarca* (1869); Zambini, *Studi sul Petrarca* (1878); Symonds, *Renaissance in Italy* (1875-86); books on Petrarch by Baldelli and by Fracassetti, by Robinson and Rolfe (1898), and Holloway-Calthorpe (1907); Maud Jerrild, *Petrarca, Poet and Humanist* (1909); E. H. R. Tatham, *Francesco Petrarca: the First Modern Man of Letters: his Life and Correspondence* (vol. i. 1925, vol. ii. 1926).

Petre, an English Catholic family, descended from Sir William Petre, secretary of state in the reigns of Henry VIII., Edward, Mary, and Elizabeth. The most notable member was Edward Petre the Jesuit (1631-99), who shared the captivity of his kinsman Lord Petre in the Tower in connection with Oates's 'Popish Plot.' After his release by James II., he sat in the Privy Council. He was abhorred as James's evil genius, and escaping at the Revolution became rector of St. Omers.

Petrel (*Procellaria*), a genus of sea-birds of the family Procellariidae, which includes the albatrosses, shearwaters, fulmars, and petrels proper, but is not near the gulls (Laridae). The true petrels, of which there are eighteen widely distributed species, are long-winged birds of powerful

flight; the tail is broad and of medium length; the hind-toe is very small; the claws are narrow and pointed; the bill is short and slender, and the tube-like nostrils are set close together. They are strictly oceanic, and visit coasts and islands only for breeding purposes. The best-known species is the Storm Petrel (*P. pelagica*) or Mother Carey's Chicken (q.v.), which is scarcely larger than a hawk, and is the smallest web-footed bird known. The head and back are sooty-black, the wings black, with streaks of white, the under surface grayish black, the bill black, and the feet reddish brown. The name Petrel—a diminutive of Peter—refers to its apparent walking on the water, the lightness of its body enabling it to skim up and down the waves, even in a storm, with only enough motion of the wings to keep the feet from sinking under the surface. Because of its frequent occurrence before or during stormy weather, when the molluscs and other animals upon which it feeds are driven to the surface, and possibly also because of its blackness, it is regarded by sailors as a bird of evil omen.

Storm Petrel (*Procellaria pelagica*).

Its flesh is so oily that the Faerøe islanders, it is said, draw a keep through the body to make a lamp. See PULMAR.

Petri, LAURENTIUS, Swedish Reformer, was born at Örebro in 1499, studied under Luther at Wittenberg, was made professor of Theology at Uppsala, and in 1531 first Protestant Archbishop of Uppsala, and died in 1573. Along with his brother Olaus he was chiefly instrumental in converting Sweden to the Reformed doctrines, and with him superintended the translation of the Bible into Swedish (1541), a work that also helped to fix the language.—His brother **OLAUS**, born at Örebro in 1497, died at Stockholm in 1552, gained, a few years after his return (1519) from Wittenberg, the ear of Gustavus Vasa, who called him to the capital to preach the new doctrines, and eventually made him (1531) chancellor of the kingdom. This post he resigned in 1539, and spent the rest of his life as first pastor of Stockholm. He was a man of bold temperament, great activity, and powerful eloquence, and left several works, including memoirs, a mystery-play, hymns, and controversial tracts.

Petrie, GEORGE (1789–1866), Irish archaeologist, born at Dublin, was trained a landscape-painter, but was early attracted by the old buildings of Ireland. In 1833–46 he was attached to the Ordnance Survey of Ireland, and from 1832 he contributed much to the *Dublin Penny Journal*. He wrote on Tara, Irish music, &c.; and his famous *Essay on Round Towers* proved that they were Christian ecclesiastical buildings. See the study by Stokes (1868).

Petrie, SIR WILLIAM MATTHEW FLINDERS, was born at Woolwich, 3d June 1853, and educated privately. His earliest explorations bore fruit in his *Stonehenge* (1880), and he next turned his attention to the pyramids and temples of Ghizeh (book, 1887), subsequently, with the aid of the Egypt Exploration Fund, to the forgotten city of Naukratis, and many Egyptian sites. For forty-two years he excavated in Egypt, besides occupying, from 1892, the chair of Egyptology in University College, London. He has written some sixty archaeological works, mainly on Egyptology, on which he is a supreme authority.

Petrograd. See ST PETERSBURG.

Petrography is that branch of geological science which deals with rocks viewed as aggregates of mineral matter. It is a study, therefore, which is carried on chiefly indoors, its object being to ascertain the mineralogical composition, the texture, and other physical characters of rocks, for which various appliances and apparatus are required. Although petrography is properly only a description of rocks, it is hardly possible to describe rocks without reference to their geological relations and mode of origin. Hence by many geologists the term Petrology is preferred as a name for this branch of their science, while others use Lithology in a similar sense. For a general account of rocks from the point of view of their origin, reference may be made to the section Petrology under GEOLOGY.

Petrographers are hardly yet agreed on any particular classification of rocks, not certainly from the want of materials, for a very large number of so-called rock-species have been described. But in the case of the crystalline igneous rocks so many gradations exist between one kind and another that the definition of rock-species is often very difficult. As careful descriptions multiply and comparisons are made it is probable that many of the igneous rocks which flourish at present as species will come to be included as mere varieties of a few well-marked types.

In examining a rock the petrographer notes first those characters which can be seen by the naked eye (*macroscopic characters*), such as its structure (whether *crystalline*, *vitreous*, *compact*, or *clastic*, &c.); its state of aggregation or relative hardness; its colour; its composition; and specific gravity—which may vary from 0.6 among the hydro-carbon compounds to 3.1 among the basalts, the average specific gravity of rocks in general being about 2.5 or a little more. In the case of many coarse-grained rocks, especially those belonging to the derivative division, it is hardly requisite to go beyond a macroscopic examination. But when the rock appears to be homogeneous it is necessary to subject it to closer scrutiny. Thin slices are therefore prepared for microscopic study, after which it is frequently found that the apparently smooth compact mass turns out to be composed wholly or largely either of crystalline or of fragmental materials. Even in the case of rocks which are manifestly crystalline, and the mineral ingredients of which can be determined macroscopically, it is necessary that a microscopic examination should be made. When this is done the rock will sometimes be shown to contain minute crystalline granules and crystals, or small quantities of non-differentiated matter and glass which quite escape the unassisted eye. The minute structure of the various rock-forming minerals is likewise investigated by means of the microscope, and the chemical changes which they may have undergone since the time of their formation are carefully studied. In this way much light has been thrown on the genesis of rocks and the changes which these have subsequently experienced.

Of the minerals known to science comparatively

few are rock-formers; the larger number of these are practically confined to the igneous and schistose rocks, very few entering into the formation of the derivative class. The mineral constituents of the igneous rocks are grouped as *essential*, *accessory* or *identitious*, and *secondary*. The essential minerals are the most important, as it is upon their presence that the various species of rocks depend. Accessory minerals are accidental ingredients, the presence or absence of which does not affect the specific character of a rock; if sufficiently prominent or remarkable they merely give rise to varieties. Secondary minerals are the products of chemical changes subsequent to the formation of the rock in which they occur—the essential and accessory minerals being *primary* or *original* constituents. Among the more important original constituents of *Igneous* rocks are quartz, feldspars, pyroxenes, amphiboles, biotite, olivine, nepheline, and leucite—the two last named being of less importance than the others. All the minerals mentioned are essential ingredients of some rocks and only accessory constituents in others. Now and again such minerals as muscovite, sodalite, halcyne and nosean, garnet, schorl, and sphene play the part of essential constituents, but they are more commonly met with as accessories. Besides these there are many other adventitious minerals, but only a few need be named—apatite, iron oxides, zircon, rutile, &c. Amongst the secondary minerals and decomposition products in igneous rocks are quartz, calcite, zeolites, iron oxides, chlorite, muscovite, serpentine, epidote, kaolin, &c. The more notable constituents of *Schistose* rocks are quartz, feldspars, micas, amphiboles, chlorite, serpentine, garnet, &c. Less prominent ingredients are andalusite, staurolite, kyanite, magnetite, pyrite, schorl, epidote, &c. The *Derivative* rocks having been formed out of the debris of pre-existing rock-masses, whether igneous, schistose, or sedimentary, it is obvious that they may contain many of the minerals already mentioned. Thus, there are some sandstones composed of quartz, feldspar, and mica—the debris of granite or gneiss. But most of the minerals which aqueous rocks have derived from crystalline igneous and schistose rocks are more or less altered—the feldspars are kaolinised, the micas are reduced to non-elastic scales or folia of a dull gray colour and much diminished lustre, the pyroxenes, amphiboles, olivine, &c., are either unrecognisable or represented by decomposition products. Quartz, as might have been anticipated, owing to its resistance to the chemical action of water and its superior hardness, is the most common mineral constituent of derivative rocks. The clay-rocks consist in large measure of the insoluble residue of the various silicates of alumina and the alkalies and alkaline earths of which igneous and schistose rocks are so largely composed. The readily soluble and readily precipitated minerals calcite, dolomite, rock-salt, and gypsum are also important rock-formers in certain groups of derivative rocks. As binding materials (i.e. the mineral cements which hold the grains of many sedimentary rocks together) we have quartz, chalcedony, opal, &c., calcite, hematite, and limonite, dolomite, siderite, &c. The rocks which are mainly composed of organic debris necessarily consist chiefly of calcareous and carbonaceous materials.

For purposes of description rocks may be grouped in the three following divisions: (I.) *Igneous Rocks*; (II.) *Derivative Rocks*; and (III.) *Metamorphic Rocks*.

I. *Igneous Rocks* (q.v.).—Of these there are two series—(a) *crystalline* and (b) *fragmental* or *pyroclastic*. The crystalline series includes hemi-crystalline and vitreous or glassy rocks, some of the more

important characters of which may be noted. The vitreous rocks usually contain crystallites and microlites, and they often show perlitic and spherulitic structures. (See PUMICE). Others are more or less homogeneous, closely compact, and smooth like bottle-glass; while yet others are markedly porphyritic, usually with crystals of sanidine (see FELSAR). Although vitreous rocks occasionally occur as independent masses, either in the form of lava-flows or of intrusive sills, dykes, and veins, they more usually appear as the crusts or superficial parts of hemi-crystalline lavas, or as selvages or marginal portions of intrusive hemi-crystalline rocks. They are frequently discharged during volcanic eruptions as loose ejecta—cinders, slags, and scoria. The hemi-crystalline rocks are composed of crystalline minerals and glassy matter in very variable proportions. The crystalline ingredients often show minute inclusions of other minerals (*endomorphs*) or of glass, &c., which have been caught up while the crystal was growing in its molten magma. Frequently also the crystals contain minute cavities which may be empty or filled with some liquid or gas. The holocrystalline rocks contain of course no glass or non-differentiated matter. It is in this class of rocks—many of which are of plutonic origin—that liquid cavities are of most common occurrence in the constituent minerals. In the minerals of hemi-crystalline and crystalline rocks, which have been erupted at or near the surface, liquid cavities are less common. In vitreous, hemi-crystalline, and crystalline rocks alike, the mineral ingredients are not seldom disposed in lines or bands. This is called *fluxion* or *fluidal* structure—the ingredients having arranged themselves in this manner while the igneous rock was fluid and in motion. Although not unknown in some holocrystalline rocks, it is a structure which is more characteristic of the vitreous and hemi-crystalline rocks which have been poured out at the earth's surface as lavas. The appearance of the original mineral constituents of many igneous rocks shows that they did not all separate out from the molten magma at one and the same time. In most cases they belong to two stages in the consolidation of the rock of which they form a part. Thus, in many crystalline and hemi-crystalline rocks, we readily distinguish a crystalline or hemi-crystalline ground-mass, scattered through which occur larger crystals, many of which may be broken and corroded. These latter are believed to have crystallised while the molten rock was still at a considerable depth below the surface. Afterwards, when the molten mass was poured out at or near the surface, and cooled rapidly, the smaller minerals and glassy matter of the ground-mass were formed. Although these two classes of minerals can be seen most clearly in volcanic rocks with a porphyritic aspect, yet even in granitoid rocks evidence of two stages or periods of consolidation can often be detected. The general character of fragmental igneous rocks is discussed under AGGLOMERATE, TUFF, and IGNEOUS ROCKS. Most of the rocks mentioned in the following tables have separate articles assigned to them.

(I.) CRYSTALLINE (INCLUDING VITREOUS) ROCKS.

1. Rocks with alkali feldspar as the dominant constituent: granite, quartz-porphry, rhyolite, pitchstone, obsidian, amygd, orthoclase-perphyry, trachyte, phonolite.
2. Rocks with soda-time feldspar as the dominant constituent: diorite, andesite, gabbro, dolerite, basalt.
3. Rocks with feldspathoids as the dominant constituents: nepheline-basalt, leucite-basalt.
4. Rocks without either feldspars or feldspathoids: peridotites, limburgite, ngilite.

(J) FRAGMENTAL OR PYROCLASTIC ROCKS.

1. Volcanic agglomerate, volcanic breccia, tuff, volcanic sand, ash, and dust, scoria, lapilli, blocks, and bombs.

II. *Derivative Rocks*.—As water has played

very prominent part in the formation of this great division of rocks, these are frequently termed *aqueous* or *sedimentary*. Such being the origin of by far the greater number, we find that they generally occur in layers or beds, hence the name by which they are also widely known—*stratified* rocks. Some of the members of this division, however, are not of aqueous origin, while others do not occur in beds. But they are all alike in so far as the materials of which they consist have been derived by epigene agents from the degradation of pre-existing rocks, minerals, and organic bodies.

(a) MECHANICALLY-FORMED ROCKS.

1. *Subaerial and aëlian rocks*: soil and subsoil, rock-rubble, ram-wash, &c., laterite, terra rossa, blown sand and dust, some sandstones.
2. *Sedimentary rocks*: conglomerate, sandstone, grey-wacke, clays (many varieties), shales, mudstones.
3. *Glacial rocks*: rock-debris, moraines, boulder-clay or till, tillite.

(b) CHEMICALLY-FORMED ROCKS.

Stalactites, stalagmites, calc-sinter, some magnesian limestones, rock-salt, gypsum, siliceous sinter, flint, some ironstones.

(c) ORGANICALLY-FORMED ROCKS.

Limestones (many varieties), carbonaceous rocks (peat, lignite, coal, &c.), guano, bone-breccias, coprolites, some ironstones.

III. *Metamorphic Rocks*.—The commonest rocks in this division are more or less crystalline and schistose or foliated (see FOLIATION). Some metamorphic rocks, however, show faint traces of either crystalline or foliated structure, while others, although crystalline, may be wholly devoid of foliation. Certain types, again, are characterised by *cataclastic* structure—they have been crushed into fragments, and in many cases even pulverised, without acquiring a thoroughly crystalline and schistose structure.

(a) *Schistose Rocks*: schistose conglomerates, quartzschist, clay-slate (numerous varieties), phyllite, micaschist, chlorite-schist, talc-schist, amphibole-schist, gneiss (many varieties), eclogite, marble, serpentine, &c.

(b) *Cataclastic Rocks*: mylonites, friction, crush, and fault-breccias.

Petrol, known also as '680 spit' (from its specific gravity, '680), 'motor spirit', 'motorine', and 'carburene', is a product, by distillation, of Petroleum (q.v.), largely used in the internal combustion engines of automobile vehicles and aircraft. It is also made of the specific gravity of '700, especially for motors.

Petroleum ('rock-oil'; Lat. *petra*, 'rock,' *oleum*, 'oil'), an inflammable substance, essentially liquid in form, composed of carbon and hydrogen, and found impregnating the rocks of the earth's crust, or as a superficial exudation. In its narrow sense the term is restricted to the liquid phase of the material; but there are gradations both to the solid and gaseous condition, and the term is often used broadly to cover both these variations.

(1) *General History*.—Perhaps some of our earliest references to petroleum are from the Middle East. The ruins of Nineveh and Babylon show that petroleum was in use at the dawn of history; the asphaltic mortar used in their buildings was made from a partially evaporated petroleum, obtained, doubtless, from the springs of Is, on the Euphrates. This is probably the 'slime' of the Old Testament Scriptures (Gen. xi. 3). Herodotus (i. 119; iv. 195), 500 B.C., writes of the springs in the island of Zante, 'I have myself

seen pitch drawn out of a lake and from waters in Zacynthus,' &c. Strabo (xvi. 2) refers to the bitumen found in the valley of Judaea, and sold to the Egyptians for embalming. Diodorus describes the same products obtained from a lake in Sicily, and sold for the same uses. Pliny, Plutarch, Aristotle, and Josephus mention the deposit in Albania on the Adriatic Sea. The holy fires of Baku on the Caspian Sea, worshipped for ages by the people dwelling near, and the goal of pilgrimages even from India (see Vigne's *Travels in Kashmir*), have been sustained by apparently inexhaustible petroleum stores. In the Far East there are indications of a very early petroleum industry, both in China and Burma. In the former natural gas was used as a source of heat in the salt-panning trade, while from the latter the old Rangoon oil was a well-known article of commerce long before the modern petroleum industry came into being. This Burma oil was obtained from hand-dug wells near the banks of the Irrawadi, and relics of this old industry still exist side by side with the modern derricks at the present day. In Europe there are occasional references to petroleum in early mediæval literature, and the *Asphon* asphalt was a well-known occurrence from which material was obtained for caulking the bottoms of ships. The North American Indians collected what was known as Seneca oil from petroleum springs, and the indications are that long before them the Mound Builders, who worked the copper-mines of Lake Superior, the lead-mines of Kentucky, and the mica-mines of North Carolina, not only gathered the oil coming from natural springs that appeared on streams, but even dug numerous wells in Pennsylvania, Ohio, and Canada, and dipped up the oil that flowed into them. Trees now growing in the earth thrown out in digging the wells, or in the wells themselves, show that the work was done from 500 to 1000 years ago.

(2) *Natural History*.—The question of the origin of petroleum has been the subject of acute controversy, but whereas there is no doubt that hydrocarbons in various forms may have had very diverse modes of formation, yet it is generally agreed that the commercial supplies of petroleum have been formed from organic matter. The old theories of Berthelot and Mendeleef, though interesting, are now no longer held seriously. The organic matter from which the petroleum is produced has been entombed in the sediments and changed into hydrocarbons either practically contemporaneously by bacteriological decomposition or later by destructive distillation. The question whether this organic matter was originally terrestrial vegetation, marine vegetation, or marine animal matter, is still debated. There is a certain amount of evidence favouring the idea that it is its fatty constituents that have given rise to the hydrocarbons, and it is significant that in the few cases where geological evidence is available it should have pointed to diatoms and foraminifera, both of which are known to contain such fatty matter.

Agreeing that hydrocarbons have been formed from the entombed organic matter contained in argillaceous or calcareous sediments, there must ensue a process of migration whereby the oil and gas are driven into the porous sandy or dolomitic strata and there trapped in suitable reservoirs. The forces governing this movement are probably the compaction of the sediments, moving currents of sea-water, the relative density of gas, oil, and water, the vehicular action of gas, changes in temperature, and capillarity. Later, when the rocks are deformed in the folds and fault blocks, the trapped hydrocarbons are redistributed so that the gas and oil are held in the higher portions of

the geological structures and underlain by the salt water. Hence the anticlinal theory of oil occurrences, which states generally that the oil and gas occur on the crests of the anticlines or domes, and that the salt water lies in the contiguous synclines. This sweeping statement needs some reservations, and it is qualified by the known lenticularity of many oil strata, but broadly it is no doubt fundamentally true. There are, however, many oil pools which are not located on anticlines: such structures as geological terraces, monoclinal noses, salt domes, fault blocks, and a number of others are all of importance in determining the localisation of oil pools, while it must be admitted that in certain cases of relatively horizontal beds the localisation of the oil pools is rather a question of the texture of the rock than of actual general structure. In the search for new oil and gas pools the geologist is largely guided by the geological structure of the region, the lithology of the underlying formations, and the superficial oil indications. These latter are really examples of oil or gas escaping from the underground reservoir. They occur in the form of gas, oil, or viscous asphalt. In the form of gas, there are the continuous flows of gas bubbles in running and stagnant water, and the mud volcanoes which form such spectacular features on the landscape in countries like Trinidad and Colombia. The oil usually forms thin films on running streams or pools, and gas and oil are often associated. Often this oil, especially when asphaltic, thickens and hardens on exposure to the surface, and leaves a cake or layer of pitch. The area around the Pitch Lake in Trinidad (q.v.) is an excellent example of such an occurrence.

(3) *The Growth of the Industry.*—Although petroleum has been known from very early times it was not until the refining of the crude material to produce a usable lamp oil was successfully accomplished that any serious progress was made to found the modern petroleum industry. This was first accomplished by a German chemist in the case of the crude Galician oils, and the illumination of the old station at Prague is probably the first instance of the use of refined crude petroleum in industry for illuminating purposes. At approximately the same time the shale industry of Scotland had come into being, and it is interesting that when the Drake well started the flood of oil in America several refineries were already in being in that country which had been originally constructed to deal with shale oils. The Drake well of 1858-59, so called because E. L. Drake was superintendent of the Pennsylvanian Rock Oil Company which conducted the drilling operations, was by no means the first oil well in the United States. Many such wells had produced petroleum inadvertently when salt water was looked for, but the Drake well can justly claim that it was the first well which was drilled in the United States intentionally for petroleum. It was drilled in Oil Creek, and after many difficulties, caused by caving sands, it succeeded in striking oil on 28th August 1859. The discovery was followed by a stampede of drilling, and the market was soon glutted. Oil boom followed oil boom. Rapidly expanding oilfields cropped up where previously had been virgin country, and many of these fields disappeared again and are now the home of quiet agricultural activities. New townships rose almost in a night, fortunes were won and lost, and all the evils of a primitive community attended each successive oil boom. In these early days the market, though growing, was limited. The refinery capacity also was limited, and every new field meant a fall in oil prices until the flow had diminished sufficiently or demand had again overtaken supply. This early industry shivered in its worst form all the symptoms

of a disease which has attended it ever since. McKean, Warren, Elk, Forrest, Erie, Crawford, Venango, Clarion, Butler, Washington, and Greene counties are only some of the famous oil pools which made the Pennsylvanian fields justly famous. Soon, however, the wild-catter went farther afield. Canada and Ohio were early rivals, but never attained the production in quality and quantity of the Pennsylvanian oilfields. The 20th century saw the wave of production extending westwards. Kansas, Oklahoma, the Gulf States, and California soon became successful rivals, and it was not long before Pennsylvania was left far behind in the race. Nowadays the Mid-Continental field and California account for the main bulk of the oil production in the United States. These two groups of oilfields are responsible for practically half the oil supplies of the world. They are still growing in importance, and it is impossible to say how long this process will last. Other fields also show signs of increase, and the Rocky Mountain oilfields have grown into importance. This rise of petroleum production has been obtained by almost unrestricted wild-cating and competitive drilling, with rapid price fluctuation following each new big oil discovery, yet the demand has continually increased, and supply has had to increase correspondingly. The demand of the automobile industry, which soon over-towered every other demand, has shown no signs of diminution, and indeed the increase of petroleum production and the increase in automobiles in the States have gone hand in hand.

At the same time other countries have joined in the race, and some have attained great importance. In 1900 Russia more than outstripped the United States, and became for a short period the prime producer, to be left hopelessly behind, however, in a few years, when the Mid-Continental oilfields came into being. Mexico, perhaps, has had a more spectacular history than any other oilfield. Few areas can show such phenomenal wells, such rapid growth in output, and, finally, such a sudden check to further growth. The unrestricted flow of oil in this area brought its own Nemesis, for water troubles, elsewhere usually slow in their incidence, were a rapid disturbing factor in Mexico, and in 1922 she received a rude shock. Galicia, Rumania, the Dutch East Indies, Peru, and Burma have all added their quota to the flood of oil, while on the horizon at the present moment loom Persia and Venezuela, both of them countries of large wells, both of them apparently with large untapped resources, and with the possibilities of an ultimate production which may be of primary importance to the world. Meanwhile the United States production has grown and grown. The limits prophesied by scientists to its ultimate production have all been exceeded, and there is as yet no sign of a wane. We have not yet reached a state when increased demand cannot quickly produce an increase of supply, and with the improvement in drilling technique and the application of scientific geological methods in the search for new pools, it is difficult at the moment to say how long this increase will last. Nowadays commercial production can be obtained from 4000 and 5000 feet, and although the cost of such wells is much greater than those of 2000 or 3000 feet, the enhanced supply of oil that is often obtained more than counterbalances the increase in expense.

(4) *Methods of Production.*—The early methods of drilling in China and Burma were by hand-dug wells or by a primitive percussion system. The latter system is the basis of the modern standard system. For this and for the rotary system, see MINING. There are many modifications, particularly of the standard system. In

Canada, for instance, they use ash poles instead of the drilling line, while in Rumania and Galicia these poles are replaced by iron rods. Diamond drilling has been introduced by several oil companies, but largely for exploratory rather than for production purposes. See BORING.

In most oilfields in their early stages of development the oil is under sufficient gas-pressure to drive it up the casing to the surface of the ground, and indeed in some cases the pressure is so great that the oil gets out of control and breaks loose as an oil gusher, often flooding the countryside. Thus the famous Potrero Del Llano No. 4 of Mexico is said to have wasted 8 million barrels, and the La Rosa well of Maracaibo Gulf flooded the countryside with over 1 million barrels of oil in about ten days. Such gushers cause great waste. They often lead to oilfield fires, and their owners may be involved in large claims for compensation. Nowadays the drilling in of a well under such conditions is carried out with great care in order to maintain control of the flow in every phase of the operation. When, however, a field gets old its pressure diminishes, the oil no longer rises to the surface, and it has to be lifted either by means of a bailer, or more usually by means of steam or electric pumps. Of recent years compressed air has been utilised with marked success in maintaining production in deep wells, and in some cases water-pressure has been used to increase production in some of the older fields. However, the introduction of water into an oil sand is an exceedingly dangerous process, and in most cases ruins its production. All oilfields ultimately die down in their productivity, and either the wells change to salt water by the rise of the edge water which surrounds most oil pools, or the oil flow becomes so small as to be hardly worth pumping. It is interesting, however, to note that it is probable that when an oilfield has ceased production more than 50 per cent. of the original oil still remains underground, and one of the problems of the future is how economically to extract this large residuum. It may be even that the oil producer of the future will resort to processes of mining similar to those now carried out at Pechelbrom in Alsace, though many difficulties have to be overcome before such mining methods will be applicable in the larger oilfields.

(5) *Refining*.—Crude oil as obtained direct from the wells varies greatly in its density, colour, viscosity, and volatility. Oils of good quality, such as the Pennsylvanian oils, are usually light brown or green in colour, mobile, volatile, and have a specific gravity about .85. Medium quality oils are darker and more viscous, while the heavy oils are usually dark brown to black viscous liquids, ranging from .9 to 1 in specific gravity, and containing only small quantities of the lighter fractions which are generally most in demand. Other factors governing the value of a crude oil are its asphaltic and paraffinous nature, and the percentage and form of the sulphur-bearing impurities. Most oils have to undergo some process of refinement before they are placed on the markets, though in the case of the poorer asphaltic oils this refinement may be merely for the purpose of extracting the small percentage of the volatile oils, and selling the rest as crude fuel. Further, the process of refinement depends to a large extent on the quality of the oil and the needs of the local market, and the refinery is able to adapt itself to changing conditions by altering its refinery technique and producing variable proportions of refined products. This is well displayed in the increasing proportion of petrol which is now obtained to supply the demands of the automobile industry. Before 1900 the main refined product from crude petroleum was the

kerosene used for illuminating purposes. Nowadays the pivot of the industry is petrol. The process of obtaining these various refined products is primarily dependent on fractional distillation. The crude oil is heated in stills of different sizes and shapes. The most common one adopted is a horizontal cylinder made of iron or steel plates $\frac{1}{2}$ -inch to $\frac{3}{4}$ -inch thick, partly enclosed in brickwork, and heated usually by a fuel oil-burner. An upper outlet carries the vapours over into a long series of pipe or worm condensers, which are either cooled by air or immersed in cool water to get a more efficient condensation. The first products of distillation are the lighter hydrocarbons, which are almost completely volatilised by ordinary temperatures. These form the petroleum-ether portion of the distillates. Then follow in order the various types of petrol, beginning with the more volatile aviation spirits and merging towards the benzine types, which are intermediate products between petrol and kerosene. The illuminating oil distillates are then distilled over, and in this phase of the distillation a certain amount of steam is usually introduced into the still to facilitate distillation at a lower temperature. If the distillation is carried to completion after the kerosene distillate we have various types of gas oils, and should the oil be suitable for the production of lubricating oils, these latter form the final distillates. However, in such cases the final phases of the distillation are usually carried out in some sort of a pot still, and the residual coke is left finally in the pot still, to be extracted mechanically when the latter is cool. The yields of the various products vary greatly according to the grade of the crude, and also according to the different products which the manufacturer finds it most desirable to make. The losses in distillation are usually less than 5 per cent. From the various crude distillates specialised

products can be produced by further distillation, but before these distillates are redistilled they are usually treated with sulphuric acid and caustic soda in large vertical stills. These mixing chambers usually have a conical bottom, the oil is charged into the container, the chemical is added in known quantity, and the oil is agitated usually by means of a strong air-blast. The tar produced by the interaction of the acid or the soda on the oil sinks to the bottom, and the purified oil can be removed, when it has separated out from the tar. The distillate so treated is usually washed with water, and is ready for use. The heavy oils left in the primary still after distillation often contain both lubricating oil-stock and a certain amount of paraffin wax. To extract the wax from the heavy oil the residuum is subjected to cooling processes, and is then passed through a filter press, wherein the oil is pressed out of the crystallised wax. The crude wax so obtained is usually re-treated in sweating-houses kept at certain constant temperatures, whereby the paraffins of different melting-points are segregated and purified. The cylinder oil-stock is usually redistributed either under a vacuum or by means of some quite special stills, and is separated into different types of lubricating stocks, which are afterwards blended to produce the lubricants of commerce. To avoid the use of sulphuric acid and caustic soda some refineries utilise various types of absorbents such as bauxite, fuller's earth, and flordin. These materials have the power of extracting the darker particles which discolour oils, and are extremely useful in clarifying various types of lubricants. In general we may divide up the petroleum refineries into four main types, though it is admitted that any such classification is to a certain extent artificial. The first type is the crude, simple refinery, which is often built close to an oilfield. In this case the plant consists essentially

of simple stills, usually of the horizontal boiler type, and the oil is distilled into its three main fractions, petroleum, kerosene, and fuel oils. Though the technique is usually crude, some of these refineries have an enormous through-put, and they depend for their profits on a cheap local fuel, and on the universal demand for petrol. The second type of refinery is the specialised complete refinery, built more usually on the main lines of transport and in close touch with the main markets. Those of the Atlantic sea-board of the United States are good examples. The refineries employ a much more complicated plant. They are built to have a large through-put, they employ a large technical staff, and they differentiate their products in order to produce a large number of specialised distillates, according to the needs of the market. They are essentially the refineries from which the main bulk of the lubricating oil is obtained in commerce; and although they find it difficult with their large overhead costs to compete with the more crude refineries in the production of petrol, they get their profits largely from their concentration on the lubricating oils. The third type of refining plant is called a skimming plant, which is essentially designed to treat a poor crude and obtain from it all its most volatile constituents with the least waste of heat energy. The design of such plants is specialised, but they all attempt to obtain a rapid through-put, and to utilise the cool incoming oil to condense the vapours of the volatile distillate, so that the heat loss is largely reduced by this interchange. Fourthly, we have the cracking processes, of which perhaps the Burton and the Cross are the best known. A heavy fuel oil is destructively distilled at a high temperature and pressure. This causes the breaking up of the molecules into simpler and more volatile hydrocarbons. The paraffins are broken up into olefins and more volatile paraffins, and at a still higher temperature the benzene hydrocarbons are broken up similarly to paraffins and olefins. These cracking plants are largely designed to meet the growing demand for petrol. Their products are a cracked spirit and residual fuel oil with a certain amount of carbon. The cracked spirit is treated chemically to remove its rather disagreeable odour, and is then usually blended with straight-run spirit, and is sold on the market in this intermixed condition. There is no space within the limits of this article to deal with the whole series of by-products, such as greases, waxes, medicinal oil, lamp black, &c., which are all produced from crude petroleum; but it is sufficient to say that the products of this material can be numbered in hundreds, and enter intimately in all directions into the various needs of modern civilisation.

(6) *Transport and Storage.*—Petroleum is a liquid, and in many of its forms it is highly volatile and inflammable. Hence the transport of the crude and of its refined products has involved special problems, and has had to be done by specialised means. There has grown up, therefore, in the petroleum industry a section dealing only with the transport, and large companies dealing merely with this side of the subject, and commanding an immense capital, have been formed to carry the oil from the oilfields to the markets and to deal with its storage. In the early days the crude was carted in barrels or transported in barges. On the railways crude barrel transport soon gave place to the specially constructed tank-car, but it was in the development of the pipe-line transport that the greatest advance was made. Samuel Van Syckle of Titusville, Pennsylvania, put down the first successful line, extending from Pithole to Miller's Farm, a distance of 4 miles. His pipe-line threatened the old oil transporters with unemployment, and riots followed. The same

trouble occurred when the first pipe-line was constructed from the Caspian to the Black Sea. However, the new system was so economical that it grew by leaps and bounds. Oil can be pumped into a branch line in the Mid-Continental oilfield and appear later at a tank farm on the Atlantic sea-board, over 1500 miles away. The large transporting companies at the same time have constructed immense tank farms for storage purposes. They have become, in fact, the buyers of crude oil, and as buyers their interests have often clashed with the producers'. As a result there have been many economical battles between these two sides of the industry, with serious disturbances in the normal trend of production. A normal pipe-line usually consists of long lines of 4-inch, 6-inch, 8-inch, or 10-inch steel tubing, screwed together by means of collars in 20-foot lengths, and laid either in covered trenches or exposed on the surface of the ground. At intervals of 15 to 50 miles there are constructed pumping-stations, which intercept the oil coming along the pipe and pump it forward at a pressure often as high as 800 lb. to the square inch to the next station. Sometimes, when the crude is exceedingly viscous, the oil is heated in its passage in order to reduce its viscosity. Railway transport is largely concerned with refined products, and the modern tank-car, with its specially built undercarriage and its safety-valves, is one of the best-built units of the freight-train. The convenience of carriage in bulk soon led to the construction of the oil-tanker, a specially built ship with oil storage in large bulkheads, and engines and boilers placed astern. These have grown until the modern types have a capacity of 15,000 to 20,000 tons, and with the introduction of the semi-Diesel engine, fire-risks have been greatly reduced.

For storage, the modern tank farm, as it is called, is usually a collection of 25,000-barrel or 55,000-barrel steel tanks, built in separate units, each usually surrounded with a small wall. Such tanks, of course, are built in all sizes, but it is found that the 55,000-barrel tank is the most economical. In California immense concrete-lined reservoirs, roofed over with a board or a felted roof, have been built, capable of storing as much as 2,000,000 barrels.

Finally, any short statement of the petroleum industry would be inadequate which failed to draw attention to its self-containedness. It has kept control of every branch of the activities associated with petroleum, and has developed an enormous marketing system which reaches to the most remote parts. From the earth to the consumer seems to have been the ideal of the industry, and in attaining this aim it has built up great organisations like the Standard and the Shell, whose interests are world-wide, and whose activities extend far beyond the obvious rôles of production, transport, and refining. The command of petrol and fuel-oil resources is essential to a nation in time of war, and the clashing interests of various nationalities, all eager for a share in these essential fuel resources, have added one more element to the causes of strife, already far too many.

Pétroleuse, a name given to the women of the French Commune of 1871, because they helped to burn the Tuileries, Hôtel-de-Ville, and other public buildings by pouring petroleum on them.

Petrology. See GEOLOGY, PETROGRAPHY.

Petromyzon. See LAMPREY.

Petronel, an ancient and clumsy pistol.

Petronius, surnamed 'ARBITER,' from his supposed identity with the Gaius Petronius whom Tacitus calls 'arbiter elegantiae' at the court of

Nero, is generally believed to be the author of the satirical romance or collection of satires of which the 15th and 16th books have, though in a fragmentary state, come down to us. The work seems to have been a novelty in Latin literature, consisting of prose and verse, and depicting the licentious life in Southern Italy of the upper or moneyed class. Its artistic merit is great, in strength of portrayal and colour anticipating Zola, with a vein of humour as original as it is refined, though the coarseness underlying is very patent. Bücheler and Friedländer, its best editors, Cesareo and Collignon, amongst recent critics, support the long-prevalent view that its author was no other than the Petronius above referred to—a pro-consul of Bithynia and afterwards consul, a past master in all the arts of the voluptuary, the aider and abettor of Nero and the *jeunesse dorée* of the 1st century in every form of sensual indulgence. The favour he enjoyed at court aroused the jealousy of another confidant of the emperor's, Tigellinus, who had influence enough with their common master to procure his disgrace and banishment. He had proceeded as far as Cumæ, when Nero's casual presence in Campania precipitated his determination to destroy himself. True to the cynical side of his philosophy he set about his suicide in the most leisurely fashion, so as to glide out of existence 'without indecent haste.' He opened his veins at intervals and then rebanded them, discoursing the while not on immortality or the hollowness of life, but on the gayest of topics, and listening to songs and *vers de société* when not transacting business or taking a siesta. Shortly before expiring he drew up, signed, sealed, and sent to Nero a summary of the tyrant's amours and excesses, much of which is supposed to have been embodied in his satires. The *Satyricon* of Petronius, of which the *Cena Trimalchionis* is the chief piece, gives a vivid picture of the 1st century on its seamiest side, and in style touches the high-water mark of silver-age Latinity.

See editions by Bücheler (1904), Friedländer (1890), and Heseltine (with translation 1913); Collignon's *Étude sur Petronius* (1892); J. M. Mitchell, *Petronius Leader of Fashion* (transl. and notes 1924).

Petropavlovsk, a town of western Siberia, on the river Ishim and the Siberian railway, 190 miles WNW. of Omsk; pop. 36,000.—PETROPAVLOVSK KAMCHATSKY, in Kamchatka (q.v.) has an admirable harbour.

Petropolis, a town of Brazil, 25 miles N. of Rio. It was originally a colony of Germans (1845), and was capital of the state of Rio de Janeiro in 1894-1903. Its hill scenery and climate attract Rio people in summer. Pop. about 30,000.

Petrovsk, a town of Russia, 65 miles NW. of Saratov, on the tributary of the Don. Pop. 20,000.

Petrozavodsk, capital of Karelia, on the western shore of Lake Onega, 300 miles NE. of St Petersburg. Peter the Great started an iron-works in 1703. Pop. 14,000.

Petrus Alfonsus. See FABLES.

Petsamo (Russ. *Petchenga*), an ice-free Arctic port of Finland, in a tongue of territory ceded by Russia in 1920, whereby Russia is now cut off from contact with Norway.

Pettenkofer, MAX VON, chemist, was born near Neuburg on the Danube, 3d December 1818; studied at Munich, Würzburg, and Giessen; and in 1847 became professor of Chemistry at Munich. He made many valuable contributions to science on subjects as various as gold-refining, gas-making, ventilation, clothing, the influence of soils on health, epidemics, and hygiene generally. His

Handbuch der Hygiene (1882) was famous. He resigned in 1894, and shot himself 10th February 1901.

Pettie, JOHN, painter, was born at Edinburgh, 17th March 1839, was brought up at East Linton, studied art at Edinburgh, and died at Hastings, 21st February 1893. 'The Prison Pet' was exhibited at Edinburgh in 1859, and 'The Armourers' at the Royal Academy in 1860. But the first work which showed his characteristic qualities of strong imaginative grasp of his subject, effective composition, and vigorous treatment was the 'Drum-head Court-martial' (1864). Among the hundreds of later pictures, including portraits, may here only be named 'An Arrest for Witchcraft' (1866), 'Scene in the Temple Gardens' (1871), 'Juliet and Friar Laurence' (1874), 'The Death Warrant' (1879), 'The Vigil' (1884), and 'The Chieftain's Candlesticks' (1886). Pettie was elected A.R.A. in 1866, and R.A. in 1873. See his *Life and Paintings*, by Martin Hardie (1908).

Petty, SIR WILLIAM, a man of singular versatility, best known as a political economist, was born at Romsey in Hampshire on 26th May 1623, and educated partly at Caen, partly at the universities of the Netherlands, and at Paris. His versatility and talent are evidenced by the positions he successively held, and the subjects he interested himself in: he taught anatomy and chemistry at Oxford (1648), and was made professor of Anatomy there (1651); was professor of Music at Gresham College, London; was physician to the army in Ireland (1652), executed a fresh survey of the Irish lands forfeited in 1641, started ironworks, lead-mines, sea-fisheries, and other industries on estates he bought in south-west Ireland; was secretary to Henry Cromwell when he was lord-lieutenant of that island; was made surveyor-general of Ireland by Charles II., who knighted him; invented a copying-machine (1647) and a double-keeled sea-boat (1663); and in early life took much interest in education. In political economy he claims a place as one of the most important precursors of Adam Smith, on the strength of his *Treatise on Taxes and Contributions* (1662) and his *Political Arithmetic* (1691), the latter a discussion of the value of comparative statistics. He died in London on 16th December 1687. His *Economic Writings* were edited by C. H. Hall (1899).

Petty Bag Office, one of the branches of the Court of Chancery, was abolished in 1874.

Petty Officers in the Navy hold a similar rank and position to the non-commissioned officers in the Army. They are the backbone of the service, as the efficiency, smartness, and morale of a ship's company depend in no small measure upon the zeal and discretion of the petty officers. They are now a most highly trained and valuable body of men, and all the warrant-officers and some commissioned officers are drawn from their ranks. They are divided into three classes—viz. chief petty officers, petty officers, and leading seamen—and into seven branches—military (seaman class), engineer, artisan (shipwrights, plumbers, armourers), medical, accountant (ship's stewards and writers), regulating (ship's police), officers' stewards. A chief petty officer can only be disgraced with the sanction of the commander-in-chief, and in the case of a chief engine-room artificer his disgracing must be specially reported to the Admiralty, and he can only be restored to his rank by Admiralty order. All other petty officers can be appointed or disgraced by the captain of the ship, except in the case of gunnery or torpedo instructors, who are rated as such for their special qualifications in the gunnery and torpedo schools. See WARRANT-OFFICERS.

Petunia, a genus of plants of the natural order Solanaceae, natives of the warmer parts of America. They are herbaceous plants, very nearly allied to Tobacco,

White Petunia.
(*Petunia nyctagyniflora*).

and with a certain similarity to it in the general appearance of the foliage, which has also a slight viscosity, and emits when handled a disagreeable smell; but the flowers are very beautiful, and varieties improved by cultivation are amongst the favourite ornaments of British greenhouses and flower-borders. The petunias, although perennial, are very often treated as annuals, sown on a hotbed in spring, and planted out in summer, in which way they succeed very well even in Scotland. They are tall plants, with

branching weak stems, and may readily be made to cover a trellis. Though, when treated as greenhouse plants, they become half-shrubby, they live only two or three years. The name is from the Tupi *Petuu*. The first petunia was introduced into Britain in 1831. There are now many garden varieties with double flowers, individually more durable than the single-flowered kinds.

Petuntze. See FELSPAR, POTTERY.

Petworth, a market-town of Sussex, on an eminence near the West Rother River, 14 miles NNE. of Chichester. Petworth House (18th century) has a fine park and many portraits and other relics of the Percies and Wyndhams.

Peucedanum. See DILL, PARSNIP, SULPHUR-ROOT.

Peutinger, CONRAD (1465-1547), a scholarly citizen of Augsburg, and keeper of the archives. He published a series of Roman inscriptions; and at his death the so-called *Tabula Peutingeriana* was in his possession, in course of being prepared for publication. This remarkable Itinerary (q.v.) is really a Roman map of the military roads of the 3d century A.D., though his copy was probably a 13th-century one. The document was sold by his family, bought by Prince Eugene in 1714, and is now in the National Library at Vienna. It was edited and published by Scheyb (1753), Mannert (1824), and Desjardins (1869).

Pevensey, a village of Sussex, stands on the English Channel, 12 miles by rail W. by S. of Hastings. The Romans built here a castle, whose walls enclose a Norman keep. The church is Early English. William the Conqueror landed on the shore of Pevensey Bay. An ancient borough and 'limb' of the Cinq Ports, Pevensey had a mayor and corporation till 1886.

Pews (anciently *puys*; Old Fr. *puys*: Dutch *puys*; Lat. *podium*, 'anything to lean on'—*s'appuyer*), enclosed seats in churches. Church-seats were in use in England some time before the Reformation, as is proved by numerous examples still extant, the carving on some of which is as early as the Decorated Period—i.e. before 1400 A.D.; and records as old as 1450 speak of such seats by

the name of *puys*. They were originally benches, usually facing east, with partitions of wainscoting about three feet high, and ends of the width of the seat, panelled or carved; these ends often rising above the wainscoting, and ending in fleurs-de-lis or 'poppy-heads,' as shown in the illustration.

Pews, Fressingfield Church, Suffolk.

The benches here are in Fressingfield Church, Harleston, Suffolk, and date from the latter half of the 15th century. The back of the one in the engraving is quite a 'poor man's Bible,' being carved with the emblems of the Passion, from the cock crowing to the seamless coat. In later times pews grew into large and high enclosures, containing two or more seats, lined with baize, and fitted with doors, desks, and cushions; but these will soon have all been swept away in England under the influence of the restoration movement and of the Free and Open Church Association founded in 1865 for the abolition of appropriated seats. Pews were early assigned to particular owners, but at first only to the patrons of churches. A canon made at Exeter, in 1287, rebukes quarrelling for a seat in church, and decrees that none shall claim a seat as his own except noblemen and the patrons. Gradually, however, the system of appropriation was extended to other inhabitants of the parish, to the injury of the poor, and the multiplication of disputes.

The law of pews in England is briefly this. All church-seats are at the disposal of the bishop, and may be assigned by him, by faculty, to persons owning property in the parish. Long occupation may give an owner of property a prescriptive title to a pew. Subject to rights acquired by faculty or prescription, the churchwardens are required to find seats for the parishioners, according to their degree; they may assign a pew to a parishioner, but the right thus conferred may at any time be recalled. In new churches pews may be assigned and pew-rents levied under several acts of parliament. See Dale's *Clergyman's Handbook*. It appears that by common law every parishioner has a right to a seat in the church, and the churchwardens are bound to place each one as best they can. The practice of letting pews, except under the church-building acts or special local acts of parliament, and, much more, of selling them, has been declared illegal.

In Scotland pews in the parish churches are assigned by the Heritors (q.v.) to the parishioners, who have accordingly the preferable claim on them; in towns the practice is to let them annually. As

is well known, pews in dissenting churches are rented as a means of revenue to sustain general charges. In some parts of the United States pews in churches are a matter of annual competition, and bring large sums. In England, there has been some discussion as to the injuriously exclusive character of the 'pew system,' and in many churches the open seats or chairs are unappropriated and free to all. In a good many Ritualistic churches the sexes are divided. In Catholic churches abroad pews are seldom seen.

Pewter, a common and very useful Alloy (q.v.) of tin and lead. It was once largely used for making mugs, plates, and the like; but the poisonous character of the lead brought it into disfavour, and some governments prohibited its use. Old pewter is now prized by collectors.

Pézenas, a town of France (dept. Hérault), on the river Hérault, 32 miles SW. of Montpellier; pop. 7000.

Peziza, a large genus of Discomycete Fungi (q.v.), growing on decaying wood and elsewhere. Its often brightly coloured cups may be stalked or sessile. *P. Willkommii* is the cause of larch canker. *P. aeruginosa* on dead oak branches stains the wood green.

Pfäfers, hot springs in the canton of St. Gall, Switzerland, in the deep and gloomy gorge of the Tamina torrent, which joins the Rhine at Ragatz, 2½ miles to the north. They were discovered towards the middle of the 11th century, and have been used ever since. Patients used formerly to be let down by ropes, but they can now approach by a good road. The water (97° F.) is conducted in pipes to Ragatz, though there are bath-houses (1704) in the ravine. Near the village of Pfäfers, which stands above and outside the ravine, is a Benedictine abbey, founded in the 8th century, but converted into a lunatic asylum after its dissolution in 1838.

Pfalz, the German name for the Palatinate (q.v.).

Pfalzburg. See PHALSBURG.

Pfitzner, HANS, German conductor and composer, born at Moscow, 5th May 1869. He has taught and conducted at Coblenz, Mainz, Munich, Berlin, and Strassburg. Somewhat Wagnerian in spirit, he has composed operas (*Der arme Heinrich*, 1895; *Die Rose vom Liebesgarten*, 1901; *Palestrina*, 1917), and many pieces for orchestra, strings, and voices. He has also written books on musical subjects.

Pfleiderer, OTTO, a great philosophic theologian of Protestant Germany, was born at Stetten, near Kannstadt, 1st September 1839; studied under Baur, at Tübingen, from 1857 till 1861, and next paid a visit of study to England and Scotland; became pastor at Heilbronn in 1868, and superintendent at Jena in 1870, an office which in the same year he exchanged for the chair of Theology there. In 1875 he was called to be professor of Systematic Theology at Berlin. In New Testament criticism Pfeleiderer belonged to the critical school which grew out of the impulse given by Baur. But he was not the less an independent thinker, acute, suggestive, and profoundly learned. He died 20th July 1908.

His brother, EDMUND PFLEIDERER (1842-1902), born at Stetten, studied at Tübingen, and after a short experience as a pastor was made professor of Philosophy at Kiel in 1873, whence he was called to Tübingen in 1878.

Pforzheim, the chief manufacturing town of Baden, stands at the northern border of the Black Forest, 20 miles SE. of Karlsruhe by rail. It contains the remains of an ancient castle, from 1300 to 1565 the residence of the Margraves of

Baden-Durlach, and was the birthplace of Reuchlin. The town is famous for the manufactures of gold and silver ornaments, and has further chemical and iron works, machine-shops, tanneries, paper and other factories. There is a trade in timber, cattle, ornaments, &c. The town was burned by the French in 1689. Pop. (1871) 19,801; (1900) 43,351; (1925) 78,859.

Phædrus (or PLEDER, according to some scholars), author of a translation of Æsop's fables in Latin verse, was, by his own account, a Macedonian, who from his childhood was imbued with Greek culture. While still young he came to Italy, and in Rome or some other city attended school where he studied Ennius, whom he quotes in the epilogue to his third book. From the title of the entire work, *Phædri Augusti Liberti Fabularum*, it appears that from a slave he became the freedman of Augustus, either the first of that name or his successor Tiberius. Under the reign of this latter he published the first two books of his fables, but his biting though veiled allusions to the tyranny of the emperor (in the fable of the frogs asking a king) and to his minister Sejanus (in that of the jay dressed in peacock's plumage) caused him to be hated at court, then accused, and finally condemned—to what punishment is unknown. On the death of Sejanus he resumed publication, and dedicated his third book to one Eutychus, freedman of the Emperor Claudius, courting his protection from enemies and accusers. In the last years of his life, to which the fourth and fifth books belong, he seems to have regained liberty of pen as well as of person. He died probably at an advanced age. Phædrus was more than he claims to be—a reproducer of Æsop; he invented fables of his own, and gave an Æsopic turn to contemporary events. That the five books traditionally ascribed to him are his cannot without large deductions be maintained—not a few of them may be of the same authorship as the *Fabule Novæ* commonly added as an appendix to the five books, and found in an anthology attributed to Nicola Perotti, a scholar of the 15th century. The merits of Phædrus are his clear succinct narrative, his pure Latinity, and his skill in versification. There is a good edition by Postgate (1922).

Phæthón ('the shining'), in the writings of Homer and Hesiod, a frequent title of Helios the sun god, and subsequently employed as his name.—Phæthón, in Greek mythology, is also the name of a son of Helios, famous for his unfortunate attempt to drive his father's chariot. Scarcely had the presumptuous youth seized the reins, when the horses, perceiving his weakness, ran off, and, approaching too near the Earth, almost set it on fire. Whereupon the Earth cried to Zeus for help, and Zeus struck down Phæthón with a thunderbolt into the Eridanus or Po. His sisters, the Heliades, who had harnessed the horses of the Sun, were changed into poplars, and their tears into amber.

Phagedæna. See ULCERS.

Phagocytes, amoeboid cells which devour intruding microbes and other cells, or ingest irritant particles, or carry disintegrated nutritive material from one part of the body to another. They are found in almost all multicellular animals from sponges to mammals; and in backboneed animals they are particular kinds of white blood corpuscles or leucocytes, which are able to leave the blood-vessels. They are active in inflammation, which is an attempt to deal with invading microbes or poisoning or other abnormal conditions; they sometimes take part in the metamorphosis of an animal, or in the regeneration of a lost part, or in degenerative processes. The manifold rôle of phagocytes was first made clear by the researches

of Metschnikoff, and it is interesting to notice that it was his pupil Bordet who discovered the complementary rôle of the serum of the blood in destroying bacteria. See BLOOD.

Phalstos. See CRETE.

Phalacrocorax. See CORMORANT.

Phalanger, a group of small arboreal marsupials, of which many species are found in Australia and the islands to the north of it. All the species have long, prehensile tails, and many grasp their food and convey it to the mouth with their forepaws. They feed usually on the young shoots and leaves of the trees in which they live, but in captivity they do not refuse animal food. Phal-

Vulpine Phalanger

anger (*Phalangista*) is a book name, 'opossum' being the (inaccurate but) popular appellation; the common opossum of Australia being *Trichosurus vulpecula*. The cuscus is a true phalanger. The Dormouse Phalanger (*Dromicus nanus*), which is only six inches in length, resembles the common dormouse in habits and appearance. Closely allied are the Flying Phalangists. See FLYING ANIMALS. The Wombat and Koala belong to kindred groups.

Phalanstère. See FOURIER.

Phalanx, the ancient Greek formation for heavy infantry, was a series of parallel columns standing close one behind the other, the whole owing to its depth and solidity capable of penetrating any line of troops. The oldest phalanx was the Lacedæmonian or Spartan, in which the soldiers stood four, six, or, more generally, eight deep. The arms of the men were swords, shields, and long pikes or spears.

Phalaris, tyrant of Agrigentum, in Sicily, who flourished about the middle of the 6th century B.C., was born on a small island near Cnidus, in Asia Minor, and whilst building a temple in the citadel of Agrigentum made himself master of the city. He greatly embellished it, and extended his power over large districts in Sicily. But after holding power for sixteen years he was overthrown, for his cruelties, by noble families of the island, and roasted alive in his own invention, the brazen bull. The tradition points probably to the religious sacrifice of human victims to Baal or Moloch (q.v.). Later ages represent Phalaris as a humane and enlightened ruler. But the 148 letters bearing his name were proved by Bentley (q.v.) in 1697 and 1699 to be spurious, and to have been composed several centuries after Phalaris died. See Bentley's *Dissertation*, edited by W. Wagner (Lond. 1883).

Phalarope (*Phalaropus*), a genus of wading-birds, related to sandpipers, dunlin, redshanks, and the like, noteworthy for the foot-like toes with lobed webs suited for both swimming and running, and for the fact that the female courts the male, who is of duller plumage, and the male performs most of the duties of incubation. The beautiful Red-

necked Phalarope (*P. hyperboreus*) is a rarity in Britain, still nesting in the Shetlands, Orkneys, and Outer Hebrides, breeding plentifully in the Far North. The Grey Phalarope (*P. fulicarius*) is a winter visitor to Britain; it breeds in the Far North, both in Eurasia and America.

Phallus, the Greek term for the symbol of generation which figures in the rites and ceremonies of most primitive peoples, and appears as a survival amongst civilised peoples. At the time when Mythology (q.v.) was universally considered to contain the teaching of ancient sages couched in the form of allegory, and everything in mythology was considered to be 'symbolical' of some profound and hidden truth, phallic worship was naturally conceived to conceal some esoteric teaching as to the mystery of the transmission of life. But this view of mythology is dissipated by an examination of the manner of life and mode of thought of those savage peoples in whom the scientific observer recognises primitive man. The savage leads not a speculative but a practical life, and his rites and ceremonies are practical. He lives in the midst of dangers, which as a practical man he wishes to avert; he has a variety of needs, which as a practical man he wishes to satisfy. Amongst the most important of his needs is the need of fruitful flocks, of fertile fields. Amongst the means which he employed to secure fertility were some which we should discriminate as magical, though probably to him they originally seemed to be not more supernatural or less rational than plunging. Thus, it was proved to demonstration by Mannhardt (*Baumkultus*) that one of the beliefs most widely spread amongst primitive men is the belief in a spirit of vegetation. The tree is regarded first as having life like a man, then as being the abode of a spirit, and finally the spirit ceases to be permanently attached to the tree. The savage has special means for promoting the vigour, for preventing the decay, for averting the displeasure of these spirits on whom the fertility of his crops depends. These various means are usually of the nature of what has been termed 'sympathetic magic.' When the savage wishes flocks to multiply, his 'sympathetic magic' inevitably takes the form of a ritual which to us may seem obscene, but is to him as harmless and necessary as the act of generation itself.

Phallus, a genus of fungi. See FUNGI.

Phalsbourg, or PFALZBURG, a town of Lorraine, stands on the north-west shoulder of the Vosges, 25 miles NW. of Strasburg. It was fortified by Vanban in 1680; invested, but not taken, by the Allies in 1814-15; and bombarded and taken by the Germans in 1870, after which they razed the fortifications. It was the birthplace of Erckmann, and is widely known through *Le Blois* and others of the Erckmann-Chatrian novels. Pop. 4000.

Phanariots. See FANARIOTS.

Phanerogamia, or SPERMATOPHYTES, are those plants which produce seeds. For the differences and the resemblances between the flowering and seeding of Phanerogams and the reproduction of Cryptogams, see CRYPTOGRAMIA, FLOWER, GYMNOSPERMS, SEED. The group includes the following sets of plants: A. Gymnosperms (q.v.), with naked ovules—e.g. conifers; B. Angiosperms (q.v.), with ovules enclosed in ovaries: (1) Monocotyledons (q.v.), with one cotyledon—e.g. lilies, grasses, orchids; (2) Dicotyledons (q.v.), with two cotyledons—e.g. buttercups, roses.

Pharaoh, the English spelling of the name given by the Hebrews to the monarch ruling in Egypt at the time, sometimes as if it were a proper name, though really an official title (from the

Egyptian *Peraa* or *Phouro*). The greatest difficulties have been encountered in attempting to determine the particular monarchs who pass under this name in the Scriptures. See EGYPT.

Pharisees (*Perúshim*, 'separated'), a so-called 'Jewish sect,' more correctly a certain Jewish school, which probably dates as a distinct body or party from the time of the Syrian troubles, and whose chief tendency it was to resist all Greek or other foreign influences that threatened to undermine the sacred religion of their fathers. They most emphatically took their stand upon the Law, together with those inferences drawn from its written letter which had, partly from time immemorial, been current as a sacred tradition among the people. They originated as the Chasidim (q.v.), and became known as Pharisees in the time of John Hyrcanus (see MACCABEES). Principally distinguished by their most scrupulous observance of certain ordinances relating to things clean and unclean, they further adopted among themselves various degrees of purity, the highest of which, however, was scarcely ever reached by any member of their community. For every degree a special course of instruction, a solemn initiation, and a novitiate was necessary; all of which, together with a certain distinction in dress, seems to have been initiated from them by the Essenes (q.v.). The name of Pharisees or *Perúshim* was probably at first bestowed upon them in derision by the Sadducees or Zadokites, the priestly aristocracy and their party, who differed from them politically, and to some extent also in religious matters. The Pharisees had no articles of creed different from the whole body of Jews. The Bible, as interpreted by the traditional Law, was their only code. Obedience to this Law, strictest observance of all religious and moral duties, submission to the Divine will, full confidence in the wisdom and justice of Providence, firm belief in future reward and punishment, chastity, meekness, and forbearance—these were the doctrines inculcated in their schools. They were, in fact, nothing more nor less than the educated part of the people, who saw in the rigid adherence to the ancient religion, such as it had developed itself in the course of centuries, the only means of saving and preserving the commonwealth, notwithstanding all its internal and external troubles. Hence they wished the public affairs, the state and all its political doings, to be directed and measured by the standard of this same Divine Law; without any regard for the priestly and aristocratic families, the Sadducees (q.v.), and the heroes and sagacious statesmen, who had brought the Syrian wars to a successful issue, and had, by prudent negotiations with other courts, restored the nation to its former greatness. The latter held that religion and state were two totally different things; that God had given man the power of taking his matters into his own hands; and that it was foolish to wait for a supernatural interference, where energy and will were all that was required.

Naturally enough, the political difference between the two parties by degrees grew into a religious one. And the more the Sadducees lost their influence (the people siding with the Pharisees), the more the religious gulf must have widened between them; although the divergence between them, as far as our authorities (Josephus, the New Testament, and the Talmud) go, does not seem to have been of so grave a nature as is often assumed. Thus, the Pharisees assumed the dogma of immortality; while the Sadducees held that there was nothing in the Scripture to warrant it, and, above all, that there was no need of any future reward. While the Pharisees held all the traditional ordinances in equal

reverence with the Mosaic institutions, the Saddu-

cees, certain laws of purity, and some parts of the civil law. It may perhaps even be assumed (as by Geiger) that the Pharisees were the representatives of a newer Halacha, inspired by an oppositional and religious and national zeal which carried them far beyond the original boundaries. Certain other legal differences between the two parties, such as the application of the laws of inheritance to daughters, or of the responsibility of the master for his servants, are nothing more than political party-views in a religious mask, which were meant to meet certain special isolated cases only. In general the Pharisees handled justice in a much milder manner than their antagonists, who took their stand upon the rigid letter, and would hear of no mercy where a violation of the code was clearly made out. Out of the midst of the Pharisees rose the great doctors and masters of the Law (Heb. *shafirim*; Gr. *nomodidaskaloi*, 'teachers of the law,' usually rendered 'scribes'), and to them were entrusted by the later rulers the most important offices. The greatest misconception has prevailed even among scholars respecting this patriotic, pious, learned, and national party of progress. That there were among them those who were a disgrace to their party none knew better than the Pharisees themselves; and, in bitterer words than were ever used by Christ and the apostles, the Talmud castigates certain fanatical members of their own community as the 'plague of Pharisaism.' Pharisaism—from which gradually branched off the wild democratical party of 'Zealots' (*Kanainim*) in the revolution of Bar Cochba (q.v.)—has, from the final destruction of the commonwealth to this day, remained the principal representative of Judaism as a creed.

The Pharisees were essentially the popular party—that is to say, they were of the people and for the people. Their views of life, reflected in their parables, legislation, and politics, make this abundantly clear. They were the party of progress, and it was their aim to render life under the Roman yoke compatible with fidelity to Judaism, and Judaism not too hard a sacrifice for its adherents. Thus, while the *Lae tianus* had probably never been observed for centuries, Pharisaic ordinances fixed the principle of compensation as henceforward paramount. Similarly, the enactment of the *Proshul* was a great concession to the agricultural classes. The Pharisaic legislation aimed at preserving principles while modifying practices. To the Pharisees, inward religion and the fatherhood of God were fundamental; brotherly love was held to extend to the widest limits, including an almost unrestricted universalism, a belief which was complementary to that of the choice of Israel for the Law and Divine Mission. Naturally, a party which existed so long, and which underwent such striking vicissitudes, contained diverse elements, and verdicts on the Pharisees are often vitiated by stressing exceptional and extreme members and regarding them as typical. Pietists in all ages and in all religions have suffered in the same way. To day secularists and newspapers of a certain class habitually pillory a professional clergyman who is convicted of a felony, or a man who, noted for outward religious observances, is discovered secretly to have committed a breach of social or moral law. Yet generalisations drawn from such isolated instances are recognised as devoid of value, and are usually based on ignorance, if not on malice. To a very great extent the Pharisees have suffered from similar misconceptions. The Pharisees who 'act like Zimri and await the

reward of Phineas' (*Sotah*, 22b), the 'shoulder' Pharisees (who wear their good deeds on their shoulder, in ostentation), the 'wait-a-while' Pharisees (who say, 'Wait while I do this good deed'), the 'bruised' Pharisees (who bruise themselves against a wall in their haste to avoid passing a woman), and other classes are as sternly castigated in the Talmud as in the Gospels. [See *Aboth de R. Nathan*, ed. Schechter, pp. 55, 62.] Yet this is but a part of the picture, and a small part. Jesus does not praise the true Pharisees, because such praise was self-evident and unnecessary in his day; at the present time some corrective is required because his denunciations have been misinterpreted and applied to the whole instead of to the minority. Thus writers, who ought to know better, charge the Pharisees with exclusiveness, forgetting their eagerness to traverse land and sea in order to make one proselyte. The Pharisees exerted themselves to bring the world under the wings of the Shekhinah; yet, because of their uncompromising opposition to idolatry and all thereby implied, they have been styled particularists. Naturally among the Pharisees there were some who loved Rome and Greece, who appreciated classical literature, art, and institutions, and who formed friendships with non-Jews. Equally naturally there were Pharisees to whom anything extra-Palestinian was hateful. It must be remembered that, for this attitude, environment was largely responsible. When Greek culture was exhibited merely by the sensuality of Antioch, when Roman institutions were exemplified by the gladiatorial conflicts, can it be regarded as surprising that rabbis warned their disciples against such a course of life as these examples represented? On the other hand, Pharisees who saw Rome and Greece at their best were not slow in expressing their appreciation.

In recent days, Graetz, the pioneer of modern Jewish historians, writing for a generation newly emerged into academic freedom, consequent upon the enlargement of the ghetto so largely due to Napoleon, takes too little note, perhaps, of the effect of Christianity. But Graetz was writing for Jews who had to be taught that they too possessed a history, and that there was such a thing as 'the science of Judaism.' The master work of Graetz, if it can be said to possess a shortcoming, errs on the side of concentration of Judaism; it has been described as 'Judaocentric.' But the work of the Christian school in Germany is vitiated by more serious faults. Schürer's gigantic and learned work (*History of the Jewish People in the Time of Jesus Christ*, Eng. trans. 1886-90) contains numerous mistakes, always to the detriment of the Pharisees, never to their credit. These were pointed out by the late Dr I. Abrahams in his presidential address to the Oxford Society of Historical Theology (*Jew. Quart. Rev.* xi. 626). Yet they persisted in the second edition. The cause of their bias is a pre-judgment of the issue or, more directly, the error of regarding Pharisaism as a foil to the Gospels, an error equally detrimental to a due appreciation of either. This error is characteristic of certain other scholars, such as Weber, whose book is described by Travers Herford (*Pharisaism*) as 'mischievous' (p. 77), 'abounding in flagrant misrepresentation' (pp. 125-26), though it contains 'much that is extremely valuable to those who know how to use it' (p. 235). This verdict, *matutis mandatis*, applies to Bousset, and is reflected in such works as Gloag's *Conflict of Religions in the Roman Empire*. To gain a correct idea of the Pharisees, and a true and balanced opinion of their merits and demerits, the reader is referred to the works of Travers Herford, Strack and Billerbeck, Wünsche, Box, Oesterley, Lukyn Williams, Danby, Foakes-Jackson, Lake,

C. G. Montefiore, I. Abrahams, and Schechter. The articles in *Ency. Brit.*, Hastings's *E.H.E.*, and *Jew. Ency.* (and their bibliographies) will serve to supplement the information given above, and lead the student further into a study of the subject. An account of a rival (?) sect may be read in Schechter's *Jewish Sectaries* (Camb. 1910), and a new theory of the relation of Pharisees and Sadducees in Gaster's *Schweich Lectures on The Samaritans* (Oxf. 1926).

Pharmacopœia. This term has been applied to various works, consisting for the most part of (1) a list of the articles of the *Materia Medica*, whether simple or compound, with their characters, their modes of preparation, and the tests for the determination of their purity; and (2) a collection of approved receipts or prescriptions, together with the processes for preparing articles in the *Materia Medica*. Almost every civilised country of importance has its pharmacopœia; those of the United States, Germany, and France deserving special mention. The earliest pharmacopœias were prepared by the Arabs from the 9th to the 12th century, and subsequently by the medical school of Salerno. The first pharmacopœia published under authority appears to have been that of Nurnberg in the year 1542. Valerius Cordus, afterwards professor at Wittenberg but then a student, showed a collection of medical receipts, which he had selected from the works of the most eminent writers, to the physicians of Nurnberg. The latter were so struck with its value that they urged him to print it for the benefit of the apothecaries, and obtained for his work the sanction of the city council. Before this time the books chiefly in use amongst apothecaries were the treatises: *On Simples* by Avicenna and Serapion; the *Liber Servitoris* of Balchasin ben Abetazeim; and the *Antidotarium* of Nicolaus de Salerno, arranged alphabetically. This work was commonly called *Nicolaus Magnus*, to distinguish it from an abridgment known as *Nicolaus Parvus*.

Confining our remarks to the British Pharmacopœias, we may notice that the first edition of the London Pharmacopœia (or, more correctly speaking, of the Pharmacopœia of the London College of Physicians) appeared in 1618, and was chiefly founded on the works of Meze and Nicolaus de Salerno. Successive editions appeared in 1627, 1635, 1650, 1697, 1721, 1740, 1787, 1809, 1824, 1836, and 1851, and form an important contribution to the history of the progress of pharmacy and therapeutics during the last three centuries. The nature and the number of the ingredients that entered into the composition of many of the pharmaceutical preparations of the 17th and 18th centuries would astonish most of the practitioners and patients of the present day. In the earlier editions we find enumerated earthworms, snails, wood-lice, frogs, toads, puppy dogs, foxes ('a fat fox of middle age, if you can get such a one'), the skull of a man who had been hanged, the blood of the cat, the urine and excrements of various animals, &c.; and electuaries were ordered, containing 50, 62, and in one instance—Mathiolus, his Great Antidote against Poison and Pestilence—124 different ingredients.

The Edinburgh Pharmacopœia is more modern than the London, the first edition having appeared in 1699; while the Dublin Pharmacopœia does not date further back than 1807. The latest editions of these works appeared in the years 1841 and 1850 respectively.

Until the Medical Act passed in 1858, the right of publishing the pharmacopœias for England, Scotland, and Ireland was vested in the Colleges of Physicians of London, Edinburgh, and Dublin respectively; and as these three pharmacopœias

contained many important preparations, similar in name but totally different in strength (as, for example, dilute hydrocyanic acid, solution of hydrochlorate of morphia, &c.), dangerous complications arose from a London prescription being made up in Edinburgh or Dublin, or *vice versa*. By that act it is ordained that 'the General [Medical] Council shall cause to be published, under their direction, a book containing a list of medicines and compounds, and the manner of preparing them, together with the true weights and measures by which they are to be prepared and mixed; and containing such other matter and things relating thereto as the General Council shall think fit, to be called *British Pharmacopœia*;' and by a subsequent act it is enacted that 'the British Pharmacopœia shall for all purposes be deemed to be substituted throughout Great Britain and Ireland for the several above-mentioned pharmacopœias.' The *British Pharmacopœia*, which appeared in the beginning of the year 1864, gave rise to such a general feeling of disappointment throughout the profession that the General Council brought out an amended edition in 1867. A reprint with additions appeared in 1874, and other editions in 1885, 1898, and 1914. There are also Homœopathic and Veterinary Pharmacopœias, and Pharmacopœias for some London and other large hospitals, but these are not printed by authority, nor authorised in any way by government.

The Pharmacopœia of the United States is drawn up by a national convention consisting of delegates from the various medical societies, medical corporations, and universities throughout the United States. It was first published in 1820, and a second edition appeared in 1828; a seventh edition appeared in 1893, an eighth in 1905, and a tenth in 1926.

Pharmacy, a department of the medical art which consists in the collecting, preparing, preserving, and dispensing of medicines. In Great Britain the practice of pharmacy is regulated by a series of *Pharmacy Acts*, of which the more important are those of 1852, 1868, 1869, and 1882. See ADULTERATION, CHEMISTS AND DRUGGISTS, MEDICINE, PHARMACOPŒIA, PRESCRIPTION.

Pharos. See ALEXANDRIA, and LIGHTHOUSE.

Pharsalus, now FERSALA, a town of Thessaly, to the south of Larissa, on a branch of the Salambria, and accordingly in the part of Thessaly restored to Greece in 1881; hence the Greeks had to retreat in April 1897. The district, Pharsalia, is historically notable mainly for Cæsar's great victory over Pompey, 9th August 48 B.C. See LUCANUS.

Pharynx (Gr.) is the name of that part of the alimentary canal which lies behind the nose, mouth, and larynx. Its nature and functions are described in the article DIGESTION, where an illustration will also be found. In cases of Diphtheria (q.v.) the pharynx is usually the chief seat of the disease. It is liable to ordinary inflammation or *pharyngitis*—an affection characterised by pain, especially in swallowing, without redness in the fauces or change of voice. Sometimes it proceeds to suppuration, and abscesses are formed. See QUINSY, THROAT.

Phascologale, a genus of marsupials of the family of the Dasyures (q.v.), containing several species, all arboreal and insectivorous; they are spread through the Papuan islands and Australia. The best-known form is perhaps the 'Tapoa Tafa' (*P. penicillata*), of the size and appearance of a rat, which commits depredations in Australian larders and is of a fierce disposition. This marsupial has a strange resemblance to the rodent Haplotis, also at home in Australia. As with a few other Muridae, the presence of Haplotis in Australia is probably the result of being transported on

floating brushwood from the Asiatic continent. The resemblance between the marsupial and the rodent is quite superficial, and cannot mean more than that the two types are similarly or 'convergently' adapted to similar conditions of life.

Phascology. See WOMBAT.

Phases (Gr. *phasis*, 'appearance'), the different luminous appearances presented by the moon and several of the planets, sometimes the whole, a part, or none of the luminous surface being seen from the earth. See MOON, PLANETS.

Phasianida. See PHEASANT.

Phasis, a river in Colchis, now called Rion or Faz. It rises in the Caucasus, and flows west into the Euxine near the ancient city of Phasis.

Phas'nide (Gr. *phasnûs*, 'a spectre'), a family of insects, including walking-stick insects (Bacillus and Bacteria), spectre-insects (Phasma), and leaf-insects (Phyllium). With the exception of Bacillus, which occurs in south Europe, they occur in the tropics—in South America, Borneo, East Indies, &c. As their names suggest, they have a striking resemblance to the twigs and leaves of the plants on which they feed and live. See LEAF-INSECT, MIMICRY.

Pheasant (*Phasianus*), a genus of gallinaceous birds of the family Phasianida; having a rather short strong bill, a little curved; the cheeks and skin surrounding the eyes destitute of feathers, and warty; the wings short; the tail long, its feathers so placed as to slope down, roof-like, on either side, the middle feathers longest; the tarsus of the male furnished with a spur. The males of all the species are birds of splendid plumage; the females have shorter tails and dull or sombre colours. There are numerous species, natives of the warm and temperate parts of Asia. The Common Pheasant (*P. colchicus*) is said to have been brought from the banks of the Phasis, in Colchis, to the south of Europe at a very remote period, its introduction being ascribed in classic legend to the Argonauts. From the Phasis it derived its Greek name *Phasianus*, the origin of its name in English and other modern languages. It was soon naturalised in Europe, and is now diffused over almost all the temperate parts of it. The date of its introduction into Britain is not known, but was certainly earlier than 1190, when King John granted William Brewer a license 'to hunt the hare, fox, cat, and wolf, throughout all Devonshire, and to have free warren throughout all his own lands for hares, pheasants, and partridges' (Dugdale's *Baronage*, vol. i. p. 701). Strangely, however, the pheasant seems never to be mentioned as a royal dish till 1680. It has long been plentiful in plantations and game-preserves, and has been introduced into almost every part of the country suitable to its habits. The abundance of pheasants in Britain, however, is to be ascribed chiefly to careful game-preservation, without which the race would in all probability soon be extirpated. No kind of game falls so easy a prey to the poacher, for in its present method of rearing it is semi-domesticated, though we can hardly include it amongst our domestic fowls.

A minute description of the common pheasant is unnecessary. The feathers on the upper part of the head are brownish green, with edgings of yellow; the neck has variations of green and blue, with reddish orange below; the breast and sides are brownish yellow, each feather tipped with purplish blue; the back and belly are variegated, the rump deep red with green and grayish reflections; the tail is dull greenish yellow, with yellowish gray, and bars of black, and a band of dull red on each side. The whole length of a male pheasant

is about 3 feet, of which the tail measures about 18 inches. The entire length of the female is a little more than 2 feet, principally in that the

Common Pheasant (*Phasianus colchicus*), male and female.

tail is much shorter than in the male. The general colour of the female is pale grayish brown and yellow, varied with darker brown, the sides of the neck tinged with red and green. The ordinary weight of a pheasant is about two pounds and a half; but when pheasants are abundantly supplied with food, and kept undisturbed, they are sometimes four pounds or four pounds and a half in weight. The pheasant, unlike the partridge, is polygamous.

The nest of the pheasant is on the ground, and is a rude heap of leaves and grasses, in which eleven or twelve olive-brown eggs are laid. But in the half-domesticated state in which it exists in many English preserves the pheasant does not pay that attention to its eggs and young which it does when more wild, and not unfrequently continues to lay eggs for a considerable time, like the domestic fowl; the eggs being removed by the gamekeeper, and hatched by hens, along with eggs from nests found among clover and hay in the season of mowing. In fact, where pheasants are reared in large numbers nearly all the birds are hatched by either common hens or incubators, which are being largely employed for the purpose. In the former method coops are employed, in front of which are runs formed by wire netting, and in this way a large number can be attended to at one time. Very young pheasants must be carefully supplied with ants' eggs, maggots, gentles, &c., and the whole difficulty of rearing them is in their earliest stage. The difficulty of rearing birds bred in confinement has led to the introduction of various forms of artificial food, several of which are excellent. Custard is largely employed, and when given fresh is eaten with avidity, and brings on the young birds rapidly. Canary-seed is good also at first. Pheasants feed very indiscriminately on berries, seeds, roots, young shoots of plants, worms, insects, &c. Beans, peas, corn, and buckwheat are frequently thrown for them in open places in woods; and they scrape up bulbous and tuberous roots in winter. They roost in trees at no great height from the ground, and poachers sometimes capture them by burning sulphur below them. During the moulting season they do not ascend trees to roost, but spend the night on the ground, when they fall a ready prey to foxes. They are fond of woods with a thick undergrowth, in which, when disturbed, they naturally seek shelter, running whilst it is possible, rather than taking flight. The male pheasant takes flight much more readily than the female, which, appar-

ently trusting to her brown colour to escape observation, often remains still until the sportsman is almost upon her. The males and females do not associate together except during the breeding season, but small numbers of one sex are often found in company. The 'short crow' of the males begins to be heard in March. In England and Scotland pheasant-shooting legally begins on the 1st of October, and ends on the 3d of February. The pheasants turned out from the gamekeeper's breeding yard into a preserve are in general supplied with abundance of food during winter, and come to the accustomed call as readily as any kind of poultry, so that the sportsmanship of a *Battue* (q.v.), in which they are killed by scores or hundreds, is of the lowest kind. Maize is one of the best foods, but barley, peas, wheat, and oats, with the usual green food, are all employed. Some pheasant rearsers use chopped meat, boiled potatoes, decayed apples, raisins, and similar dainties. It is scarcely necessary to mention that the flesh of the pheasant is in very high esteem for the table.

The female pheasant, as is the case with most other birds, in old age, or when from any cause incapable of the functions of reproduction, sometimes assumes the plumage of the male. The pheasant exhibits a remarkable readiness to hybridise with other gallinaceous birds. A hybrid between it and the common fowl is not unfrequent, and is called a *Pero*. Hybrids between the pheasant and black grouse have also occurred; and hybrids are supposed to have been produced between the pheasant and guinea-fowl, and the pheasant and turkey. None of these hybrids, however, have ever been known to be fertile, except with one of the original species. On the contrary, the offspring of the common pheasant and the Chinese or Ring-necked Pheasant (*P. torquatus*) is perfectly fertile, a circumstance which is urged in argument by those who regard them as mere varieties of one species. The ring-necked pheasant is now almost as plentiful in Britain as the common pheasant; it is a native of the forests of India and China, and is said not to breed with the common pheasant in a truly wild state, but in Britain they readily intermix. It is distinguished by a white ring almost surrounding the neck, and is of smaller size than the common pheasant, somewhat different in markings, and has a shorter tail. It is the common pheasant of the Celestial Empire. There is also the Ringless Chinese Pheasant (*P. leucollatus*), and others scarcely known here. The Bohemian Pheasant is another variety of a creamy colour, and it is much more homely in appearance. White pheasants are of not very unfrequent occurrence, and often appear spontaneously from the common variety. Pied pheasants may be bred from crossing the white and common varieties. Of other species of pheasant may be mentioned Diard's Pheasant (*P. versicolor*), a native of Japan, in which the prevailing colour is brilliant green; Soemmerring's Pheasant (*P. soemmerringii*), also from Japan, one of the most beautiful pheasants known, but terribly pugnacious; and Reeve's Pheasant (*P. reevesii*), a native of the north of China, in which white is the prevailing colour, and the tail is of extraordinary length, so that a bird not larger than the common pheasant measures eight feet in entire length. Of somewhat different type, and more nearly approaching to the common owl, are the Golden Pheasant (*P. pictus*, or *Thaunidia picta*) and the Silver Pheasant (*P. or Euploamus nycthemerus*), both natives of China, and hardy birds, the introduction of which into British preserves has been attempted with decided success. Both have long been kept in a state of domestication by the Chinese. The golden pheasant is one of the most splendid of the tribe. It has a fine

crest, and a ruff of orange and black, capable of being erected at pleasure. The tail is very long. The crest and ruff are held in great estimation by anglers for making artificial flies. Lady Amherst's Pheasant (*P. or Thaumalia amherstii*) is a native of China, resembling the golden pheasant, and with an extremely long tail. The silver pheasant is one of the largest and most powerful of the tribe, and very combative, driving the common pheasant from preserves into which it is introduced. The prevailing colour of the upper parts and tail of the male is white, finely pencilled with black, the breast and belly purplish black. The Eared Pheasant (*Crossoptilon mantchuricum*) has a sombre brown body, a vaulted beak, red face, and white throat and ears, the feathers on which stand up above the head. The Argus Pheasant (*Argus giganteus*), found in Malacca and Siam, is separately discussed (see ARGUS). The latter series of pheasants are chiefly kept in aviaries as ornamental fowls, for which purpose they are well adapted. A recent introduction, the Prince of Wales Pheasant (*P. principalis*), was discovered on the Afghan frontier of India, and is distinguished from all other pheasants in that the greater part of its wings are white, though it is somewhat different in its markings and the arrangement of its colours.

See D. G. Elliot, *Phasianide* (1870-72), Tegetmeier, *Pheasants* (1873); Price, *Pheasant-rearing* (1888); Macpherson and others, *The Pheasant* (1895); Beebe, *Monograph of the Pheasants* (4 vols. 1918-22).

Phelps, ELIZABETH STUART (1844-1911), an American authoress, was born at Andover, Massachusetts, the daughter of Professor Austin Phelps and of the authoress of *Sunny Side*. Besides lecturing and working for the advancement of women and for social reforms, she wrote a number of stories, including *The Gates Ajor* (1868), which passed through twenty editions in the year of its publication; *Beyond the Gates* (1883); *The Gates Between* (1887); *Hedged In* and *The Silent Partner* (1870); *The Story of Avis* (1877); *Doctor Zay* (1884), in which the question of professional life for women is considered; and in 1890, in conjunction with her husband, the Rev. Herbert D. Ward, *Come Forth*, a travesty of the story of Lazarus, and *The Master of the Magicians*.

Phelps, SAMUEL, the last of the old school of actors, was born 13th February 1804 in Devonport. When seventeen years old he came to London, and was engaged on the *Globe* and *Sun* newspapers as reader; among his companions being Douglas Jerrold, then, like himself, a stage-struck youth. After some experience as an amateur, Phelps joined the York circuit in the autumn of 1826, and continued in the provinces for eleven years. On 28th August 1837 he made his début in London as Shylock at the Haymarket, under the management of Benjamin Webster, making a very great success. He was afterwards engaged by Macready, but his genius did not get full scope until the beginning of his famous Sadler's Wells management, one of the most extraordinary achievements in the history of the drama. At an outlying unfashionable and unpopular theatre he for eighteen years produced a constant succession of 'legitimate' plays, attracting around him an excellent company, and educating a rough and unpolished audience to appreciation of the masterpieces of English dramatic literature. He began this apparently unpromising experiment on 27th May 1844, continued as manager till March 1862, and made his last appearance before his Islington friends on 6th November 1862. During

leaving Sadler's Wells Phelps did not attach himself to any particular theatre, appearing at Drury Lane, the Queen's, and the Gaiety theatres, and playing regularly in the provinces. On 1st March 1878, when acting Wolsey at the Aquarium (Imperial) Theatre, he broke down, and never played again. He died on 6th November 1878. Although primarily a tragedian, Phelps was an excellent all-round actor, and some of his comedy parts are among his most notable—as, for instance, Malvolio, Bottom, and Shallow. In tragedy he was famous in Wolsey, Lear, Macbeth, Brutus, Luke (*City Madam*), and Sir Giles Overreach; while among his other chief successes were Richelieu, Sir Pertinax Macmurephont, Bertuccio, Old Dornton, and Job Thornberry.

See *Memoirs*, by J. and F. Coleman (1886); and *Life and Life-work*, by W. May Phelps and John Forbes Robertson (1886).

Phenacetin, a drug prepared from carbolic acid, valuable in fevers, and, like antipyrin, of service in stilling pain and seeming rest in cases of severe headaches, insomnia, and nervousness.

Phenacodus. See MAMMALS.

Phenol, a name for Carbolic Acid (q.v.). See also AROMATIC SERIES.

Pherie, a powerful city of Thessaly, near Mount Pelion; according to legend, the ancient royal seat of Admetus and Alcestis, and afterwards of political consequence under 'tyrants' of its own, who long made their influence felt in the affairs of Greece, and repeatedly attempted to make themselves masters of Thessaly. One of these tyrants, Alexander (slain 357 B.C.), is particularly celebrated for his cruelties.

Pherecydes, an ancient Greek philosopher, born in the island of Syros, in the 6th century B.C., a contemporary of Thales. He taught the doctrine of the existence of the human soul after death; but it is uncertain if he held the doctrine of the transmigration of souls, afterwards promulgated by his disciple, Pythagoras. Of his work, a mythological system of philosophy, only fragments are extant, collected and edited by Sturz (2d ed. Leip. 1824).—Another Pherecydes, a native of Leros, who lived in the 5th century B.C., compiled mythical histories of Athens and other states, but only a few fragments remain, published in C. Müller's *Frag. Hist. Græc.* (vol. i.).

Phi Beta Kappa, by far the oldest of the American college Greek letter societies, takes its name from the initial letters of its motto, said to be Φιλοσοφία Βίου Κυβερνήτης—'Philosophy is the guide of life.' The society, 'founded on literary principles,' and intended to embrace the 'wise and virtuous of every degree and of whatever country,' was an outcome of the desire for national union, and sprang into being in the somewhat chaotic period when the old colonies had become states, but had not yet adopted a federal constitution. It was founded in 1776 (the same year as the Illuminati, q.v.), in the old 'Raleigh Tavern' at Williamsburg, Virginia, by forty-four undergraduates of William and Mary College, of whom John Marshall was one. Branches were established at Yale in 1780 and at Harvard in 1781; and later in the other principal colleges and universities of the United States. The Phi Beta Kappa is now simply 'an agreeable bond of meeting among graduates;' since 1831 its innocent mysteries have been open secrets.

Phidias (Gr. *Phaidias*), the greatest sculptor of ancient Greece, was born the son of Chanurides, at Athens about 500 B.C. His instructor in sculpture was Ageladas of Argos. To Phidias came an opportunity such as falls to the lot of few artists: Pericles, having risen to the head of affairs in the

great Elizabethans, and of the draught the 18th century from Congreve to Colman. After

Athenian state, resolved to adorn the city with temples and other public buildings fitting for the vanquisher of Persia, and he not only gave to Phidias a commission to execute the more splendid statues that were to be erected, but made him general superintendent of all the public works planned for the city. Plutarch tells us that Phidias had under him architects, statuary, workers in copper and bronze, stonecutters, gold and ivory beaters, &c. He constructed the Propylæa and the Parthenon, the sculptured ornaments of which were executed under his direct superintendence, while the statue of the goddess Athena, of ivory and gold, was the work of Phidias himself. Fragments of the metopes, frieze, and pediments of the Parthenon were carried to England by Lord Elgin (see ELGIN MARBLES). Phidias executed a colossal statue of Zeus for the Olympieum at Olympia (q.v.), also of ivory and gold; this was reckoned his masterpiece. Accused of having appropriated to himself some portion of the gold destined for the robe of Athena, and of impiety in having introduced his own likeness and that of Pericles on the shield of the goddess, he is said to have been thrown into prison, or banished, or to have fled about 432 B.C. Other works by his hand were a statue of Aphrodite at Elis, of gold and ivory, a colossal bronze figure of Athena Promachos on the Acropolis at Athens, a gilt colossal Athena at Plataea, a monument of the victory of Marathon at Delphi, and numerous others. Their prevailing characteristic appears to have been an ideal sublimity, and the imperfect relics that we can tentatively connect with his name are the most noble specimens of sculpture in the world. In 1888 there was dug out at Tanagra a red vase bearing what was believed to be the signature of Phidias. See SCULPTURE.

See A. S. Murray, *Greek Sculpture* (1880); Gardner, *Six Greek Sculptors* (1910); Schrader, *Phidias* (Frankf. 1925); Johansen, *Phidias and the Parthenon Sculptures* (1925).

Phigalia, an ancient town of Arcadia, situated in its extreme south-west corner. From its temple of Apollo, at Bassæ, 5 to 6 miles distant, a sculptured frieze representing the contests between the Centaurs and Lapithæ, and the Amazons and Greeks, was brought to the British Museum in 1812. The temple was first described by Chandler in 1765. Next to the Theseum at Athens it is the most perfect architectural ruin in all Greece, being built of fine gray limestone and white marble. It was designed by Ictinus, one of the architects of the Parthenon at Athens, and measured originally 125½ feet long and 48 broad, and had 15 columns on each side and 6 at each end, in all 38, of which 34 still stand.

Philadelphia, the chief city of Pennsylvania and the third city in population and importance of the United States, is called the 'Quaker City' and is situated on the Delaware River, about 96 miles by ship channel (36 feet) *via* Delaware Bay from the Atlantic Ocean, 87 miles SW. of New York City, and 136 miles NE. of Washington. Co-extensive with the county of Philadelphia, the city lies along the Delaware from the mouth of the Schuylkill River (which has likewise been deepened) at League Island, northward, for about 23 miles, and has an average breadth of some 8 miles. Its total area embraces nearly 130 sq. m., including towns and villages still known by the names they bore prior to their annexation to the city. There are 37 miles of water-front. On League Island is a navy yard. Philadelphia is notably 'a city of homes.' Its inhabitants are largely composed of the well-to-do middle class,

and it has within its limits more comfortable single residences than any other city in the world.

The dominant architecture of the older sections of the city is of the severely plain, substantial style which characterised its Quaker founders, and which until the second half of the 19th century held undisputed sway, its outstanding features being uniformity of design and a general employment of red brick as building material. A marked departure then took place in the style of both the public and the private buildings of Philadelphia, among the former of which the city hall (1871 *et seq.*), built of white marble upon a granite base, and covering an area of 486 by 470 feet, affords a striking instance. The height of the tower and dome is 537 ft. 4½ in.; or 573 ft. 4½ in. with the colossal figure of Penn (36 ft.), to surmount the whole, the structure being thus one of the highest in the world. Over 500 rooms (mostly offices for city officials) are comprised in it. Other buildings worthy of note architecturally are the Masonic Temple, of granite; a United States government building of granite—containing the Post-office, United States court-rooms, and other offices of the general government; a custom-house of marble, modelled after the Parthenon at Athens; a naval asylum; the United States Mint; the Academy of Fine Arts; the Academy of Natural Sciences, a massive Gothic structure with an extensive scientific library and a great museum; the Academy of Music; and the buildings of the University of Pennsylvania. The greatest historical edifice is Independence Hall, in which the Declaration of Independence was adopted. It contains the famous Liberty Bell.

Nearly every street of importance is traversed by tramways, and an underground and elevated system is in use. A great suspension bridge joins Philadelphia with Camden, on the New Jersey side of the Delaware River. There are numerous well-shaded commons in the older portion of the city, some of which were laid out by William Penn at the foundation of his 'great towne' in 1682-83; while the Fairmount Park, over 3000 acres in extent, and bisected through its entire length of 10 miles or more by the Schuylkill River and its affluent the Wissahickon, stands without a rival among the pleasure-grounds of the great cities of the New World. In this park in 1876 was held the Centennial Exhibition; and in its environs are the Zoological Garden, the beautiful Horticultural Hall and Memorial Hall—remains of the Centennial Exhibition—the Art Museum, the Laurel Hill Cemetery, &c. From the city hall to the park entrance extends a broad 'Parkway,' adorned with magnificent buildings. Among statues in Philadelphia there are bronze equestrian figures of Generals Meade, McClellan, and Reynolds; and there is a monument at Germantown to the Union soldiers, and another in the grounds of Girard College to those of its former pupils who fell in the civil war.

The churches include the old Swedes Church (1700), Christ Church (Episcopal, 1727-54), where Washington's pew is preserved, and a Roman Catholic archiepiscopal cathedral. Philadelphia has almost from its foundation been noted for its benevolent institutions, prominent among them the Pennsylvania Hospital (1751). There are many other hospitals, including those in connection with the university and the several medical schools.

The educational facilities of Philadelphia are very great. The public schools, which are numerous, are maintained at a high standard of excellence. Besides the Girard College (q.v.) the city contains the Drexel Industrial Institute; and in Philadelphia

or its immediate environs are the Williamson Free School of Mechanical Trades, state institutions for the blind and deaf and dumb, the Franklin Institute (1824, for the mechanic arts), Spring Garden Institute (for drawing, painting, and mechanical handiwork), the Episcopal Academy (1785), several Catholic colleges and convents, and Episcopal, Lutheran, and Roman Catholic theological seminaries, and Temple University. Crowning all these is the University of Pennsylvania, which began as an academy chartered by the sons of William Penn, became a college in 1755, and a university in 1779. It is now a great national centre of education. The Jefferson Medical College (1825) is one of the most famous medical schools of the United States; and there are several others, including the Medico-Chirurgical College (1880). The scientific institutions comprise the above-named Academy of Natural Sciences, the American Philosophical Society (1743), the Wagner Institute of Science, &c. The Commercial Museum, with a great collection of the world's products, is of high importance.

Manufactures, Commerce, &c.—Though in its early history noted for its extensive shipping interests, as compared with those of its sister cities, it is rather as a manufacturing than as a commercial city that Philadelphia holds a present prominence. Here are immense establishments covering acres of ground, from which millions of dollars' worth of products are issued annually for the home and foreign markets, besides smaller concerns innumerable. No city in the world possesses a greater variety of manufactures, establishments being of immense extent and employing thousands of artisans. Among the most notable of these are the Cramp Shipyards, in which some of the largest battle-ships of the United States navy have been built, and the Baldwin Locomotive Work, the greatest of its kind in the world, turning out some 480 locomotives a month. Many thousands of operatives are employed in the production of carpets, a prominent speciality of the city, and other articles of very large production are cotton, woollen, worsted, and upholstery goods. General iron and steel products employ another great fraction of the population, the single article of saws amounting in annual value to several million dollars. In addition are oil refineries, great chemical works, and a large number of smaller industries. The domestic and foreign commerce of this city is also large, but is secondary in importance to its manufactures. Shipping has greatly increased since the deepening of the rivers.

Founded in 1682 (see PENN.), Philadelphia the year after was made the capital of Pennsylvania, and soon became a place of importance. It was the central point in the war of independence, and the city still preserves the Carpenters' Hall (1770), where the First Congress met (4th September 1774), and the old State House (1735), now famous as Independence Hall, where the Second Continental Congress sat, and the Declaration of Independence (see INDEPENDENCE DAY) was adopted in 1776. At Philadelphia, moreover, the federal union was signed, in 1778; and here, too, the constitution was framed, in 1787. An interest of another kind attaches to the fact that the Protestant Episcopal Church of North America was organised here in 1786. From 1790 to 1800 Philadelphia was

the federal capital; and the first mint was established here in 1792. Pop. (1700) 4500; (1800) 70,287; (1860) 568,034; (1880) 847,170; (1890) 1,046,964; (1900) 1,293,697; (1910) 1,549,008; (1920) 1,823,779.

Philadelphian. See ALA-SHEHR; and (for Ammon or Rabbath Amman) KERAK.

Philadelphians, a mystic sect emphasising 'brotherly love' (Gr. *philadelphia*), founded in London in 1652 under the influence of Boehme by Dr John Pordage (1608-98) and Mrs Leade and others. It had for a time a branch in Holland, but disappeared early in the 18th century.

Philadelphus. See SYRINGA.

Philæ (Gr. *Philai*, Egyptian *Pālek*), an island now submerged, in the Nile, near Assuan and south of Syene. It is a small granite rock, fringed with rich verdure, about 1200 feet long and 450 broad, almost covered with ancient buildings of great architectural beauty and interest, though not of very ancient date. That to the east, a hypæthral or roofless hall, commonly called 'Pharaoh's bed,' belongs to the Greek and Roman period, and consists of fourteen great columns with capitals of various patterns, connected at the lower part by solid walls; the length is 63 feet, the width 48. The great temple of Isis, to whom the island was sacred, was mainly built by Ptolemy Epiphanes, and continued by his successors, especially by Ptolemy III., Euergetes. The processions of pilgrims approached the island from the south, were received by the priests at a flight of steps at

Island of Philæ, seen from the south-west corner.

the south-west corner, and then passed into a court with a colonnade to right and left, erected by Tiberius and later Roman emperors. To the north stood the great propylon or gateway, 60 feet high and over 120 wide. This is the oldest part of the temple, and bears the name of Nectanebes II. (about 361 B.C.). Beyond was another court with several chambers and a small chapel. Another smaller pylon gave entrance to the temple proper, at the northern end of the irregular complex of buildings (converted into a Christian church in 577). The great dam at Assuan (q.v.), as completed in 1902, did not injure the ruins; the deepening of the dam by 26 feet, carried out since 1907, has submerged them, and was said to save them from serious injury from encrusting salts. Nevertheless rapid disintegration of hieroglyphs and small details of reliefs is reported.

Philaret (1782-1867), from 1821 Archbishop of Moscow, was the greatest preacher and the most influential Russian churchman of his time.

Philately. See STAMPS.

Philemon, EPISTLE TO, is the shortest and most personal of the extant letters of Paul. It was addressed to Philemon, who is described as one of the apostle's converts, to Apphia who is probably his wife, and to Archippus 'our fellow-soldier,' who may have been his son. The epistle does not definitely state where Philemon lived, but as Colossians iv. 17 seems to assume that Archippus lived at Colossæ, and as Onesimus, who is the main theme of the Epistle to Philemon, was one of the messengers whom Paul sent to Colossæ, we are justified in drawing the conclusion that Colossæ was also the home of Philemon and Apphia. In that case it was probably at Ephesus that Philemon came under the influence of Paul, because we have no evidence that the apostle ever visited Colossæ; indeed, the Epistle to the Colossians implies that Colossæ was unknown to him. Later tradition (e.g. the Apostolical Constitutions) regards Philemon as bishop of Colossæ, and makes him out to have been a martyr. This little epistle (containing only 25 verses) which Renan has described as 'master piece in the art of letter-writing,' is a plea for Onesimus, a slave belonging to Philemon, who had wronged his master, probably by some act of theft, and escaped to Rome. In Rome, Onesimus had been brought into contact with Paul (whether there had been any previous relationship between the two can only be a matter of surmise), and had been converted by his influence. Paul's first intention apparently was to keep Onesimus with him as his own body-servant, but it soon became clear to him that Onesimus's paramount duty was to go back to his master, and make reparation for his crime. The performance of such a duty was attended with considerable risk, for the usual penalty inflicted upon a slave for such a misdeed was crucifixion. Paul, therefore, wrote this letter to Philemon and Apphia for Onesimus to take back with him, and in it he begs his master to pardon the slave who has wronged him, offering to take upon himself the responsibility for making good the theft, 'If he hath wronged thee, or oweth thee ought, put that to mine account, I Paul will repay it' (vers. 18, 19). But Paul pleads not only for the forgiveness of the slave, but that he should be welcomed back as a fellow-Christian—'a brother beloved'—a plea which shows the new attitude which Christianity had introduced toward slavery. The Apostle Paul does not attack the institution of slavery, though as Lightfoot puts it 'the word emancipation seems to be trembling upon his lips,' but he transcends it by the Christian conception of brotherhood. There is an interesting parallel to the epistle in the letter written by Pliny to Sabinianus on behalf of a runaway freedman. The genuineness of the epistle is universally recognised except in the Dutch school of radical criticism (see article by Van Manen in the *Encyclopædia Biblica*.) The best modern commentaries are those of Lightfoot, Vincent, Haupt, and Dibelius. See also New Testament Introductions of Moffatt, Julicher, Holtzmann, &c.

Philemon and Baucis, according to a classic myth, finely poetised by Ovid in his *Metamorphoses*, were a married pair, remarkable for their mutual love. Jupiter and Mercury, wandering through Phrygia, in human form, were refused hospitality by every one, till this aged pair took them in, washed their feet, and gave them such humble fare as they could provide. On going away, the gods took them with them to a neighbouring mountain, on looking from which they saw their village covered

with a flood, but their own cottage changed into a splendid temple. Jupiter permitted them to make any request they chose, but they only asked to be servants of his temple, and that they might die at the same time. When, accordingly, they were seated at the door of the temple, being now of great age, they were changed, Philemon into an oak, and Baucis into a linden.

Philharmonic Society, a musical society established in London in 1813, for the purpose of giving concerts, now entirely orchestral. Weber, Mendelssohn, and Wagner directed performances of their own works at concerts of the society. The Philharmonic Society of New York dates from 1842, and that of Berlin, which has had von Bülow, Richter, and Nikisch among its conductors, from 1883.

Philidor, the assumed name of a French family, originally called Danigan, which has produced several distinguished musicians, and a composer, François André (born at Dreux in 1726, died in London, 1795), who was even more famous as an authority on Chess (q.v.). See Allen's *Life of Philidor* (Phila. 1864).

Philip of Macedon, the father of Alexander the Great, was born probably at Pella in 382 B.C. He was the youngest son of Amyntas II. and Eurydice, and spent part of his early life as a hostage at Thebes. The assassination of his eldest brother, Alexander II. (367 B.C.), and the death of his second brother, Perdiccas III., in battle (360 B.C.), made him guardian to his nephew Amyntas, still an infant; but in a few months Philip made himself king, the rights of Amyntas being set aside. Enmities arose without and within, but they soon disappeared before the decision, the energy, and the wise policy of the young king. In the brief space of a year he had secured the safety of his kingdom, and had gained for himself a dreaded name. Henceforward his policy was one of aggression. The Greek towns on the coast of Macedonia were the first objects of attack. In Thrace he captured the small town of Crenides, which under its new name, Philippi, soon acquired great wealth and fame. The surrounding district, rich in gold-mines, proved a source of great revenue to Philip, and supplied him plentifully with the means of paying his armies, and of bribing traitorous Greeks to open the gates of many cities. After a few years of comparative leisure he captured Methone (losing an eye at the siege), advanced into Thessaly, and ultimately to the Pass of Thermopylæ, which, however, he did not attempt to force, as it was strongly garrisoned by the Athenians. He therefore directed his arms against the Thracians. After capturing all the towns of Chalcidice—the last of which was the important city of Olynthus—he made peace with the Thracians, and next year with the Athenians, who had been at war with him in defence of their allies the Olynthians. The siege of Olynthus by Philip called forth the famous Olynthian orations of Demosthenes. Philip was now requested by the Thebans to interfere in the war ('the Sacred War') which was raging between them and the Phocians. He marched into Phocis, destroyed its cities, and sent many of the inhabitants as colonists to Thrace (346 B.C.). His next step was to secure a footing in the Peloponnese, by espousing the cause of the Argives, Messenians, and others against the Spartans. Thereafter he was engaged unsuccessfully in the sieges of Perinthus and Byzantium. In 339 B.C. the Amphictyonic Council declared war against the Locrians of Amphissa; and, in the following year, appointed Philip commander-in-chief of their forces. The Athenians, alarmed at his approach into Greece in his capacity, joined with the Thebans against him; but their united army was utterly defeated

at the battle of Chéronée (338 B.C.). With Greece at his feet, Philip was now in a position to enter on the great dream of his later years—viz. to invade the Persian empire, and revenge the injuries of Greece. Deputies from the different states of Greece, except Sparta, which refused to yield, assembled in congress at Corinth, resolved to make war on the Persian king, and chose Philip as leader of their armies. Preparations were in progress for this great expedition when he was suddenly cut off by the hand of the assassin Pausanias, at a festival to celebrate the marriage of his daughter with Alexander of Epirus (336 B.C.). Philip was a man given to self-indulgence and sensuality; he was faithless in the observance of treaty obligations, and unscrupulous as to the means by which he gained his ends; but of his energy, acuteness, and eloquence it is impossible to speak too highly. He was at the same time a lover of learning and a liberal patron of learned men. See a work by D. G. Hogarth (1897), and those cited at GREECE and DEMOSTHENES.

Philip II., better known as PHILIP-AUGUSTUS, king of France, was the son of Louis VII. and Adèle of Champagne, and was born in August 1165. He was crowned joint-king in 1179, during the lifetime of his father, succeeded him in 1180, and proved one of the greatest monarchs of the Capet dynasty, while he confirmed his hold of the throne by marriage with Isabella of Hainault, the last direct descendant of the Carolingians. His first war, made upon the Count of Flanders, gave him the county of Vermandois and the city of Amiens (1185). He rigorously punished heretics and despoiled the Jews, and reduced the rebellious Duke of Burgundy to submission. He supported the sons of Henry II. of England in their rebellions against their father, and gained Beiri by cession in 1189. On the accession of Richard to the throne Philip and he set out together on the third crusade; but they quarrelled while wintering in Sicily. After staying but three months in Syria he returned to France, having taken a solemn oath not to molest Richard's dominions; but no sooner had he returned than he made a bargain with the faithless Edward John for the partition of Richard's territories in France. The fiery Richard's sudden return occasioned an exhausting war, which was closed through the mediation of Pope Innocent early in 1199. Richard died within two months after; but war with England blazed out anew, on account of the rival claims of John and his nephew Arthur of Brittany to the French heritage of King Richard, which consisted chiefly of Anjou, Maine, and Touraine. Philip embraced the cause of Arthur, but was for a while fully occupied by his quarrel with the pope. He had put away his second wife, Ingeborg of Denmark, in order to marry the beautiful Agnes of Meran, but the terror of the thunders of the Vatican forced him to replace Ingeborg upon her throne. The murder of Arthur again gave him the excuse he sought. Richard's great fortress of Château Gaillard fell early in 1204, and Philip passed in triumph over Normandy. Before the end of that year he had added to his dominions Normandy, Maine, Anjou, and Touraine, with part of Poitou, as well as the over-lordship of Brittany, hitherto a fief of Normandy. Philip took no active part in the war against the Albigenses, but devoted himself to consolidating his dominions. The great victory of Bouvines (29th August 1214) over the Flemish, the English, and the Emperor Otto established his throne securely, and the rest of his reign he was able to devote to reforms of justice and to the building and fortifying of the city of Paris. Notre Dame remains a lasting monument of this great king's administration. By his favour towards the communes and his stern

dealings with the great fœdal lords, Philip did much to strengthen the position of the monarchy. He died at Mantes, 14th July 1223.

See works by Capefigue (1842), Mazabran (1878), Davidsohn (1888), Hutton (1896), and several volumes by Achille Luchaire (1881-1912).

Philip IV., surnamed *Le Bel* or 'the Fair,' king of France, the son of Philip III., 'the Rash,' and Isabella of Aragon, was born at Fontainebleau in 1268, and succeeded his father in 1285. By his marriage with Queen Joanna of Navarre (q.v.) he obtained Navarre, Champagne, and Brié. He overran Flanders, but a Flemish revolt broke out at Bruges, and at Courtrai on the 'Day of Spurs' the flower of the French chivalry went down in thousands before the sturdy burghers. The great event of his reign was his struggle with Pope Boniface VIII., which grew out of his attempt to levy taxes from the clergy. By the bull *Clericus laicos* in 1296 Boniface forbade the clergy to pay taxes, and to this Philip replied by forbidding the export of money or valuables, thus cutting off a main supply of papal revenue. A temporary reconciliation in 1297 was ended by a fresh outbreak of the quarrel in 1300. Philip flung the papal legate into prison, and summoned the Three Estates of France, clergy, nobles, and burghers. The last two assured him of their support even in case of excommunication and interdict. Boniface replied with the celebrated bull *Unam Sanctam*. Philip caused the bull to be publicly burned, and with the consent of the States-general confiscated the property of those prelates who had sided with the pope. Boniface now excommunicated him, and threatened to lay the kingdom under interdict, but the king sent to Rome William de Nogaret, who seized and imprisoned the pope, with the aid of the Colonnas. Though released after a few days by a popular rising, Boniface soon afterwards died. In 1305 Philip obtained the elevation of one of his own creatures to the papal chair as Clement V., and placed him at Avignon, the beginning of the seventy years' 'captivity.' He compelled the unhappy and reluctant pope to condemn the Templars in 1310, and to decree their abolition in 1312. In spite of skillful defence, they were condemned and burned by scores (see *TEMPLARS*), and their wealth appropriated by Philip. Philip during his whole reign steadily strove for the suppression of feudalism and the introduction of the Roman law; but while thus increasing the power of the crown, and also that of the third estate, he converted royalty, which was formerly protecting, kind, and popular to the mass of the people, into a hard, avaricious, and pitiless taskmaster. Under him the taxes were greatly increased, the Jews persecuted, and their property confiscated; and, when these means were insufficient to satisfy his avarice, he caused the coinage to be greatly debased. He died at Fontainebleau, 29th November 1314.

Philip VI., of VALOIS, king of France, was the son of Charles of Valois, younger brother of Philip IV., and succeeded to the regency of France on the death of Charles IV. The proclamation of a king was deferred on account of the pregnancy of Charles IV.'s widow; but on her giving birth to a daughter Philip caused himself to be crowned king at Reims (May 29, 1328). His right to the throne was denied by Edward III. of England, the grandson of Philip IV., who declared that females, though excluded by the Salic law, could transmit their rights to their children, and therefore insisted upon the superiority of his own claims. Philip, however, was not only already crowned king, but he had the support of the people. His reign commenced gloriously; for, marching into

Flanders to support the count against his rebellious subjects, he wiped out the disgrace of Courtrai by vanquishing the Flemings at Cassel (August 23 1328). He was obliged to give up Navarre (q.v.), and the Salic law of succession did not apply to it, but he retained Champagne and Brié, paying for them a considerable annual stipend. The hundred years' war with England began in 1337 both in Guienne and in Flanders, but was carried on languidly for several years, the only prominent incident being the destruction of the French fleet off Sluys (June 24, 1340). Philip was a bad and faithless man, and his grasping extortion well-nigh exhausted the wealth of the country. Yet money for his pleasures and for new wars had constantly to be provided by some new tax or fresh confiscation. In 1346 Edward III. landed in Normandy, ravaged the whole country to the environs of Paris, and totally defeated Philip at Crécy. A truce was then concluded, but the devoted kingdom had no sooner been released from war than destruction threatened in the yet more terrible form of the 'Black Death.' Philip received Dauphiné in gift in 1349, purchased Majorca from its unfortunate king, and died August 22, 1350, neither loved nor respected.

Philip II., king of Spain, the only son of the Emperor Charles V. and Isabella of Portugal, was born at Valladolid, 21st May 1527. He was brought up in Spain, and carefully educated for his destiny, but grew up distrustful and reserved; cold and austere, without being virtuous; haughty and bigoted, yet without real respect for honour or religion. In 1543 he married Mary of Portugal, who died three years later, after bearing a son, the ill-fated Don Carlos. In 1548 he went to join his father at Brussels, and made a decidedly unfavourable impression upon his future subjects. Three years later he returned to Spain, and in 1554 he made a marriage of policy with Mary Tudor, Queen of England. During his fourteen months' stay in England, he found little favour with the people, and the vexatious jealousy of a wife who was plain, spare, nearly forty, and likely to be childless, prompted him to return to Brussels (September 1555). In the next half-year he became by the abdication of his father the most powerful prince in Europe, having under his sway Spain, the Two Sicilies, the Milanese, the Low Countries, Franche Comté, Mexico, and Peru; with the best disciplined and officered army of the age. The treasury, however, was depleted by the enormous expenditure of his father's wars. Henry II. of France and the Neapolitan pope Paul IV. combined to deprive him of his Italian dominions, but Alva soon overran the pope's territories, while Philip's army under Philibert of Savoy defeated the French at St Quentin (1557) and Gravelines (1558). Henry II. agreed to terms of peace at Cateau Cambrésis (2d April 1559). In January 1568 the French had captured Calais, and Mary Tudor's death followed eleven months later. Philip thereupon married Elizabeth of France (1559) and returned to Spain, where he lived the rest of his life.

The main object of his domestic policy was to concentrate all power in himself, and to this end he laboured to destroy everything resembling free institutions in any of his dominions. He ostentatiously put himself at the head of the Catholic party in Europe, but the interests of the Church in his eyes were ever identical with his own. He found the Inquisition the best engine of his tyranny in Spain, but its effect in the Low Countries was a formidable revolt, which ended in 1579 with the northern part, the Seven United Provinces, achieving independence. To replenish his exhausted treasury Philip exacted enormous contributions from his subjects, abolishing all the ancient special communal or provincial privileges of Spain, and

suppressing all insurrection and discontent by force of arms or the Inquisition. The tragic death of William the Silent (1584) and the relentless persecution of Antonio Perez show how pitiless and how persistent was his hatred of an enemy. His wife Elizabeth having died in 1568, he married in 1570 as his fourth wife his niece, Anne of Austria, whose sole surviving son afterwards became Philip III. The one great triumph of his reign was the famous naval victory of Lepanto (7th October 1571), won by his half-brother, Don John of Austria, over the Turks. In 1580, the direct male line of Portugal having become extinct, Philip claimed the throne, and despatched Alva to occupy the kingdom. But his attempt to conquer England recoiled upon himself in the hopeless disaster of the Armada. His intrigues against Henry of Navarre were foiled by his antagonist's courage, aided by the death (1592) of his own general Alexander Farnese and Henry's politic change of religion. The stubborn heroism of the Netherlands and the exasperating ravages of the English cruisers on the Spanish Main, added to financial distress at home, embittered the last years of Philip, and he died of a lingering and peculiarly loathsome disease, in the Escorial at Madrid, on 13th September 1598, under the shadow of that failure which had followed all his greatest undertakings. Philip II. possessed great abilities, but too little political wisdom to manage successfully the vast dominions which he inherited. A fanatical and gloomy bigot in religion, alien and jealous in temper, he persecuted all heretics through the Inquisition with relentless cruelty, and at the same time dealt a fatal blow to Spain by crushing that ancient, proud, and chivalrous spirit which had been the secret of its strength, as well as by cutting off the commerce of the country by oppressive exactions and by a bitter persecution of the industrious Moriscos. On the other hand he was not always received justice from historians. He can, at least, be said that his ultra-religiousness proceeded from the conviction that he was a divine agent. He was cruel and crafty, but his enemies also were not lacking in these respects. The perception of Perez seems to have had some justification, while the light shed by more recent historians upon his dealings with his lunatic son, Don Carlos, must temper with pity the accusations of callousness hurled at him by earlier writers. See CARLOS.

Philip V., king of Spain, founder of the Bourbon dynasty in that country, was the second son of the Dauphin Louis (son of Louis XIV. and Maria Theresa of Spain) of France, and was born at Versailles, 19th December 1683. In 1700 Philip, then Duke of Anjou, was bequeathed the crown of Spain by Charles II. His grandfather, Louis XIV., as he left him to take possession of the throne, uttered the famous phrase, *Mon fils, il n'y a plus de Pyrénées.* He entered Madrid in 1701, and after a long struggle against his rival, the Archduke Charles, was left in possession of his throne by the peace of Utrecht in 1713. Next year died the queen, Maria Luisa, daughter of Victor Amadeus, Duke of Savoy, whom Philip had married in 1702; and soon after he married Elizabeth Farnese of Parma, 'the termagant,' in Carlyle's phrase, who embroiled the peace of Europe for thirty years. By her influence the aims of government were committed by the amiable and weak-minded king to Alberoni. Philip was

obliged by the Quadruple Alliance to dismiss his daring and ambitious minister at the close of 1719. He abdicated in favour of his son Don Louis in 1724, but resumed the crown on his death eight months later. The ambitious queen's dearest wish was to drive the Hapsburgs out of Italy in the interests of her sons by a former marriage, but all her efforts succeeded only in securing the Two Sicilies for Don Carlos. Spain joined the coalition against Maria Theresa, and her younger son Don Philip was at first successful in conquering the Milanese; but as soon as the Silesian war was closed by the treaty of Dresden the Austrian empress poured her troops into Italy and drove out the Spaniards. At the crisis Philip, who had been for years sunk in a state of mental stupor, died at Madrid, 9th July 1746. See ALBERONI, SUCCESSION WARS, and SPAIN; and Baudrillart's *Philippe V. et la Cour de France, 1700-15* (2 vols. 1890-91).

Philip, sachem of the Wampanoag Indians, and second son of Massasoit, the ally of the Pilgrim settlers of Plymouth, succeeded his brother in 1661, and continued the friendly relations for some years. In 1675, however, goaded by the encroachments of the whites, he led a confederation of tribes against them in what is known as King Philip's War. It was a war of surprises, massacres, and destruction on both sides, but the Indian confederation steadily weakened. In the early summer of 1676 Philip's squaw and little son were captured, and sold as slaves for the West Indies; and on 12th August, at midnight, he and his remaining followers were surprised by Captain Benjamin Church. Philip was slain, his head was cut off and exposed on a gibbet at Plymouth for twenty years. Church wrote an *Entertaining History of King Philip's War* (1716; new ed., 1865); see also Washington Irving's *Sketch-book*.

Philip the Bold (*J Philippe le Hardi*), the founder of the second and last ducal House of Burgundy, was the fourth son of John the Good, king of France, and his wife Bonne of Luxembourg, and was born 15th January 1342. He was present at the battle of Poitiers (1356), where, by his heroic courage, venturing his own life to save his father's, he earned the epithet of *le Hardi*, or 'the Bold.' He shared his father's captivity in England, and on returning to France in 1360 received in reward of his bravery the duchy of Touraine, and on the death, without heirs, of Philippe de Rouvre, also that of Burgundy (1363), being created at the same time the premier peer of France. On the accession of his brother, Charles V., to the throne of France Philip had to resign Touraine, but, as a compensation, obtained in marriage Margaret, the heiress of Flanders, in 1369. In 1372 he commanded with success against the English, and in 1380 he helped to suppress the sedition of the Flemish towns against their count, his father-in-law. But the citizens of some of the populous places, especially Ghent, were only brought back to their allegiance after the bloody defeat of Rosbeek (27th November 1382), where 26,000 Flemings were left on the field. Flanders, the county of Burgundy, Artois, Rethel, and Nevers fell to him by the death of the count in 1384, and his firm and wise government quickly won the affection and esteem of his new subjects. He encouraged judiciously arts, manufactures, and commerce, and his territory—a kingdom in extent—was one of the best governed in Europe. During the minority and subsequent imbecility of his nephew, Charles VI. of France, he was obliged to take the helm of affairs, and preserve the state from insurrection and sedition within and the attacks of the English without. He died 27th April 1404.

Philip the Good (*Philippe le Bon*), Duke of Burgundy, the son of Jean 'Sans-peur' by Margaret

of Bavaria, and grandson of Philip the Bold, was born at Dijon, the capital of the duchy, 13th June 1396, and, on the assassination of his father at the instigation of the dauphin (afterwards Charles VII.), succeeded to the duchy of Burgundy. To avenge the murder of his father, he entered into an alliance with Henry V. of England at Arras in 1419, recognising him as regent of France, and heir to the throne after Charles VI.'s death. This agreement was sanctioned in the treaty of Troyes (1420). The dauphin took to arms but was defeated at Crevant (1423) and Verneuil (1424), and driven beyond the Loire. Some disputes with the English prompted Philip to conclude a treaty with the king of France in 1429. However, the English, by giving him the province of Champagne, and a large sum of money, gained him back to their side. Falling heir to Brabant, Holland, Zealand, and the rest of the Low Countries, Philip became much more powerful than his superior, the king of France, though he preferred to continue in nominal subjection. He made a final peace (1435) with Charles, who gladly accepted it even on the hard conditions which Philip prescribed. The English, in revenge, committed such havoc among the merchant navies of Flanders that Philip declared war against them, and, in conjunction with the king of France, gradually expelled them from their French possessions. The imposition of heavy taxes excited a rebellion, headed, as usual, by the citizens of Ghent, but the duke inflicted upon them a terrible defeat at Gavre (1453), though he wept over a victory bought with the blood of 20,000 of his subjects. The later part of his reign was filled with trouble caused by the quarrels between Charles VII. and his son, the Dauphin Louis (afterwards Louis XI.), who had fled from his father's court, and sought shelter with Philip, although, after ascending the throne, far from showing gratitude, he tried in the most dishonourable manner to injure his benefactor. Philip died at Bruges, 15th July 1467, deeply lamented by his subjects. Under him Burgundy was the most wealthy, prosperous, and tranquil state in Europe; its ruler was the most feared and admired sovereign of his time, and his court far surpassed in brilliancy those of his contemporaries. See Baudante's *Histoire des Ducs de Bourgogne de la Maison de Valois*.

Philliphugh, on Yarow Water, 3 miles W.S.W. of Selkirk, the property from 1461 till 1889 of the line of the 'Outlaw Murray' of the ballad. Here, on 13th September 1645, Montrose (q.v.) was defeated by David Leslie, who butchered more than a hundred Irish prisoners.

Philip Neri, ST. See NERI.

Philippeville, a seaport of Algeria, the harbour of Constantine, from which it lies 54 miles N.N.E. by rail. The town, built since 1832, occupies the site of the Roman *Buscada*, and has a magnificent harbour (1892). There are distilleries, tanneries, and a trade in wool, hides, fruit, and cattle. Pop. (1891) 15,788; (1921) 33,808.

Philippi, earlier KRENIDES, a city of Macedonia. It was named after Philip II. (q.v.) of Macedonia, who enlarged it because of the gold-mines in its neighbourhood. It is famous on account of the two battles fought in 42 B.C. between Antony and Octavianus on the one side and the republicans under Brutus and Cassius on the other, in the second of which the republic finally perished. The apostle Paul founded a Christian church here. See PHILIPPIANS. The city has been excavated by the French School.

Philippians, THE EPISTLE TO, is generally regarded as having been written by Paul during his imprisonment at Rome about the year 62 A.D. Another theory, however, with much less proba-

bility maintains that it was composed during the imprisonment at Caesarea, and Kirsopp Lake has recently propounded a third view, that Ephesus was the place of its origin. The epistle is closely related to Colossians and Ephesians, which belong to the same group and were written under the same circumstances. There has been considerable difference of opinion as to whether Philippians was written at the commencement of the imprisonment in Rome or towards its close. Lightfoot maintained the former position, and held that Philippians was a 'transitional epistle,' standing between the second group (Galatians, Romans, &c.), and the third. His main arguments were: (1) from the point of view of style the epistle has more affinities with the earlier group; (2) in Philippians iii. we have the last echoes of the old controversy with Judaism which was finished before Colossians and Ephesians were written. The majority of modern scholars, however, think that these arguments are inconclusive, and feel that there is much more ground for supposing that the epistle was the last rather than the first of the third group. The fate of the apostle was evidently nearing its crisis. The judgment of the court was about to be pronounced, and Paul is evidently anxiously awaiting the verdict. 'I am in a strait betwixt the two, having the desire to depart and be with Christ . . . yet to abide in the flesh is more needful for your sake' (i. 23-24). It is probable, therefore, if the Pastoral Epistles in their present form are not genuine (see TIMOTHY and TITUS), that this epistle was the last which came from the pen of the apostle, and constitutes his final message to the Church.

The epistle is well attested; and though its authenticity was questioned by Baur and Holsten, there is scarcely a dissentient voice among modern scholars in regarding it as a genuine work of the Apostle Paul (except, of course, in the extreme Dutch school of criticism which questions the Pauline authorship of all the epistles assigned to him).

The epistle is one of the most personal letters that Paul ever wrote. It was written to express Paul's gratitude to the Philippians for a gift which they had sent at the hands of Epaphroditus (iv. 18). Epaphroditus was taken dangerously ill in Rome, and the desire to allay the anxiety of his fellow-Christians at Philippi was an additional motive for the letter (ii. 25-30). The apostle gives an encouraging description of his work in Rome, pointing out how the 'things that had happened to him had fallen out unto the progress of the gospel' (i. 12), writes a noble plea for the spirit of humility, based upon the illustration of the incarnation (ii. 1-12), tells in a great autobiographical passage the story of his own conversion and spiritual development in order to prove that 'the righteousness which is through faith in Christ,' transcends 'the righteousness which is of the law' (iii. 1-15), and finally pours out his soul in gratitude for the liberality of the Church at Philippi (iv.).

The best modern commentaries are by Lightfoot, Jones (*Westminster Commentary*), Kennedy (*Expositor's Greek Testament*), Vincent (*International Critical*), B. Weiss, Lipsius, Haupt, P. Ewald, and Dibelius.

Philippics, originally the three orations of Demosthenes against Philip of Macedon. The name was afterwards applied to Cicero's fourteen orations against the ambitious and dangerous designs of Mark Antony. It is now commonly employed to designate any severe and violent invective, whether oral or written.

Philippine Islands, a large insular group forming a northern section of the Malay Archipelago, separated from the rest, by the Sulu

(Mindoro) and Celebes Seas, 2000 to 3000 fathoms deep. These seas are enclosed by the three insular chains of Palawan, with Balabac in the north, Sulu in the centre, and Sangir with Sias in the south, all of which lie in shallow waters, and form a geological connection between the Philippines and Borneo in the south-west and the Philippines and Celebes in the south. The archipelago is washed on the east side by the Pacific Ocean, which in the Philippine trough off Mindanao attains a depth of 5384 fathoms (the greatest depth known), and in the north-west by the China Sea (2000 fathoms). It lies in 5°-21° N. lat. and 117°-127° E. long., and comprises a vast aggregate of over 7000 islands of all sizes, ranging from mere rocks and reefs to the great lands of Luzón (41,000 sq. m.), and Mindanao (37,000 sq. m.). The other chief members of the group, collectively called Visayas, are Mindoro, 3800 sq. m.; Palawan (Paragan), 4500; Samar, 5000; Panay, 4500; Negros, 4900; Leyte, 2800; Cebu and Bohol, each 1500; Masbate, 1200. The census of 1918 gave the population as 10,350,640.

The archipelago is disposed nearly due north and south, and is essentially mountainous and volcanic, lying in the direct line of the vast igneous chain which sweeps round from Sumatra and Java through the Lesser Sunda groups and the Moluccas northwards to Formosa and Japan. In the Philippines the first link in this system going southwards is the volcanic islet of Babuyan off the north coast of Luzón; but beyond the remarkable volcano of Taal, near Manila Bay, the chain ramifies into an eastern and a western branch, which traverse the whole of the archipelago, and are continued seawards by the insular chains of Sulu and Sangir. The eastern branch develops the lofty cones of Mayon (7943 feet) and Bulusan at the south-eastern extremity of Luzón, while the western branch gives rise to those of Canlaon and Baco in Negros and Camiguin near the north-east of Mindanao; in this island the two chains converge at the head of the Gulf of Davao, where they culminate in Apo (9610 feet), highest point in the Philippines. These various ranges, which cover nearly the whole surface of the archipelago, leaving room for scarcely any plains except about the lower courses of the rivers, consist mainly of very old eruptive rocks, in many places covered by later Tertiary, Quaternary, and modern scoriae and lavas. The underground forces are still active, and reveal themselves by tremendous eruptions, such as those of Mayon in 1766 and 1900, and Taal, 39 miles from Manila, in 1911, and especially by earthquake shocks. Violent earthquakes are fortunately of infrequent occurrence, although Manila itself was nearly destroyed by earthquakes in 1600 and 1863, and there have been disastrous convulsions in many parts since then. The navigation of the inland waters is endangered not only by seismic disturbances, but also by the conflicting currents caused by opposing tidal waves, and by the typhoons, which range as far south as about 10° N. lat (see Map at ASIA).

Owing to the parallel disposition of the mountain-ranges, space is afforded for the development of several large rivers, such as the Cagayan (Rio Grande), which drains more than one-third of Luzón, flowing for 220 miles northwards between the Sierra Madre and the North Cordillera east and west; the Agno and Pampanga on the west side of the same island; and in Mindanao the Agusan and the Rio Grande de Mindanao, which flows from the centre of the island first south-west then north-west to Illana Bay in the Celebes Sea. This river is joined by the emissaries of several other lakes, and a characteristic feature of the landscape in most of the islands is the large number

of lacustrine basins, which send their overflow through short coast-streams to all the surrounding waters. The most important and best known of these in Luzón are the Pampit, which drains Lake Bombón, and the Pásig, which flows from the Laguna de Bay to Manila. Several of the basins appear to be flooded craters, while others are of marine origin, bays and inlets cut off from the sea by the eruptive matter ejected from the neighbouring volcanoes in former geological epochs.

Thanks to the general elevation of the land, and the prevailing sea-breezes, the climate, although moist and hot, is less insalubrious than that of most tropical lands. As elsewhere in the Malay Archipelago, there are two seasons, a wet and a dry, which are determined by the trade-winds, but which, owing to the peculiar configuration of the land, may be said to go on simultaneously. Thus, for all the southern and western slopes, the south-west monsoon is the wet, the north-east the dry season, the recurrence of these periods being reversed on the opposite slopes of the same ranges. At Manila, which is exposed to the south-west winds, the rains last from June to November, dry weather for the rest of the year; but this succession is elsewhere constantly modified, especially by the trend and altitude of the mountain-chains. On the other hand, the temperature varies little throughout the year, ranging from about 77° F. in December (the coldest month) to 84° F. in May (the hottest month), while the greatest extremes recorded at Manila Observatory are seldom more than 25 degrees (66°—91°). But the rainfall varies enormously, from $\frac{1}{2}$ inch in March to 20 inches in August, with a yearly average of 68 to 70 inches. Typhoons occur during the rainy season, and sometimes cause great damage. The Weather Bureau at Manila which issues timely forecasts is important.

The indigenous flora, which is nowhere surpassed in variety and exuberance, indicates a long connection of the Philippines with Indo-Malaysia, and more transitory relations with Austro-Malaysia, through Celebes. Though most of the local genera are represented in the Great Sunda Islands and Malay Peninsula, there are endemic genera too—*Alerhia* (Flacourtiaceæ), *Adelmeria*, and *Monophrymum* (Scitamineæ), *Cleistolanthus* (Loranthaceæ), *Everettiodendron* (Euphorbiaceæ), *Greeniopsis* (Rubiaceæ). Vast spaces are still covered with magnificent primeval forests containing a great number of useful plants, such as coconut, and many other palms, ebony, banyan, pandanus, bamboo, tree-ferns. The nipa palm grows in brackish estuaries. Specially numerous are the fibrous plants, such as the gigantic bejuno (a Calamus), the buri, and abaca (Manila hemp). On the plantations are grown many varieties of rice, also maize, sugar-cane, cotton, coffee, cacao, tobacco, and camote (sweet potato). Bananas, oranges, mangoes, and papayas are the most important fruits. Rubber plantations have been established in the south and give promise of a successful industry.

The fauna is much less varied. The carabao or water-buffalo, which in a domesticated state is the principal beast of burden, is found wild in some of the more remote districts. Other wild mammals are the tamarao (a buffalo), wild hog, deer, and monkeys. Bats and squirrels abound, and there are several species of civet. Crocodiles and lizards are plentiful, as are snakes, of which the python is the largest, though not the most deadly. Bird life is varied and presents some species of great beauty. The jungle-fowl is very abundant. An endless variety of forms is also offered by the insect world. Locusts breed freely in the *cogonales*, or grass wastes, and inflict much damage on crops. The fresh and marine waters abound in fishes,

turtles, molluscs, (including pearl and mother-of-pearl oysters), sponges (*Euplectella* and other exquisite kinds).

Of minerals the most widely diffused are gold and coal. There also await exploitation deposits of copper, petroleum, manganese, lead, zinc, asbestos, lime, limestone, alum, besides jasper, marble, and fine building stones. Thermal waters, chiefly sulphurous and ferruginous, occur in many places, especially in Luzón. But the mineral resources of the archipelago are little developed.

Agriculture is the principal occupation, but numerous industries have developed especially during and since the Great War. The most important are sugar-refining, cigar and cigarette manufacture, oil and timber milling, hat-making, while the live-stock industry and fishing are already important. The exports are chiefly abaca, maguey and other fibres, sugar, cigars, cigarettes, tobacco, coconut oil, copra, and hats; and imports, rice, flour, cotton-goods, iron, steel, and machinery. The bulk of trade is with the United States. There are some 800 miles of rail-road, mostly in Luzón, and over 6000 miles of public roads. Besides nearly 8000 public schools there are many technical institutions, a normal school, a state-supported university, and some smaller universities. The chief towns with their populations (1918) are as follows: Manila (the capital, Luzón), 283,306; Cebu (Cebu) 56,502; Albay (Luzón), 52,756; Iloilo (Panay), 49,114; and Iloilo (Luzón), 38,469. About 160 miles from Manila is Baguio, the summer capital.

The original inhabitants of the Philippines were undoubtedly the Negritos (*Aetas*, *Atas*, *Itas*), who at one time occupied the whole of the archipelago, but are now reduced to a few isolated groups scattered over the remoter parts of Luzón, Negros, Mindanao, and several other islands. The Indonesians and Malays at present constitute the great bulk of the population. The Indonesians (see MALAYS) are mostly pagans, whereas nearly all the Malays are either Roman Catholics or 'Moros' (i.e. Mohammedans). Like the allied races of Sumatra and Borneo, the Indonesians are distinguished by their tall stature, muscular frames, light-brown complexion, and regular features. Their chief tribes are the Tinguianes, Kalinkas, Igorrotes, Ifugaos, and Ilongotes of Luzón; the Cinarrones, Samnans, and others of the Visayas; the Subanans, Manobos, Mandayas, Bilans, Bukidnons, and Bagobos of Mindanao. They probably number about 300,000. The Moros or Mohammedan Malays, chiefly confined to Palawan and the west of Mindanao, were estimated in 1919 at 400,000 in number. All the rest of the Malays are at least nominal Catholics, and comprise two main divisions, the northern Tagalogs of Luzón and the central Visayas (Bisayas) of the Visayas Islands and parts of Palawan and Mindanao. There are about six smaller divisions, mostly in Luzón. All the different tribes and divisions have separate languages and dialects. English is superseding Spanish as the common tongue. Of foreigners, the Chinese, Japanese, Americans, and Spaniards are the most important.

The Philippines (named after Philip II. of Spain) were discovered in 1521 by Magellan (q.v.) during his circumnavigation of the globe. Legaspi, who came from Mexico in 1565 established a Spanish colony in the islands and with him came the first friars. In the succeeding centuries the colonists had to defend themselves against the Portuguese, Chinese, Dutch, English, and Moros. The English sacked Manila in 1762. Spanish rule was oppressive and taxation heavy, civil and ecclesiastical authorities strove with each other, and the tyranny of the friars was resented by the natives. The 19th century brought education and liberal ideas,

and several revolts took place, the first of importance being in 1872. In 1896 Dr José Rizal, a native patriot, suffered martyrdom. Meanwhile the country was again in revolt, when, the Spanish-American War having broken out, an American squadron under Admiral Dewey destroyed the Spanish fleet in Manila Bay (1898). The Philip-pines were thereupon ceded to the United States (1899), although a guerilla warfare was carried on by Aguinaldo, a native insurgent, till 1901. Under American rule the islands have undergone great administrative and economic advancement. At present the governor-general, appointed by the President of the United States, is the head of the executive, while legislation is in the hands of the Senate (24 members) and the House of Representatives (93), the Philippine Commission being abolished by the Jones Act of 1916. Very many of the governmental posts are held by natives.

Philippopolis (Bulg. *Plodiv*), city of southern Bulgaria, on the navigable Maritza, 110 miles by rail W. by N. of Adrianople. It manufactures silk, cotton, tobacco, leather, &c., and prepares and exports otto of roses. It has a Greek and a Bulgarian archbishop. Pop. 63,400. An outpost of the Macedonian kingdom, it was ruined by the Goths, captured by the Turks (1363), destroyed by an earthquake (1818), burned (1840), and occupied by the Russians (1878).

Philippsburg, a town of Baden on the Rhine's right bank, 16 miles N. of Carlsruhe. Fortified till 1800, it was often besieged.

Philips, AMBROSE, minor poet, was descended from a Leicestershire family, and born about 1675. He was educated at St John's College, Cambridge, and contributed to the university memorial verses on the death of Queen Mary. Coming up to London he became intimate with Addison and Steele, did hack work for Tonson, and first gained a reputation by the 'Winter-piece' in the *Tatler* (No. 12) and the six Pastorals which opened the sixth volume of Tonson's *Miscellany* (1709), of which the first four volumes had been edited by Dryden. Strangely enough the same volume closed with the Pastorals of the young Pope, whose jealousy was aroused by Tickell's praising Philips and passing over himself, in his paper in the *Guardian* on Pastoral Poetry from Theocritus downwards. Pope took a characteristic revenge by a paper in the *Guardian* (No. 40), in which the worst of the verses of Philips were ironically exalted above the best of his own. His design he dismised with such dexterity that, though Addison discovered it, as Dr Johnson tells us, Steele was deceived, and was afraid of displeasing Pope by publishing his paper. Philips is said to have hung up a rod in Button's Coffee-house with which he threatened to chastise Pope on the first occasion. Pope nourished his anger against him, and all the more, after his own

quarrel with Addison to whose circle Philips belonged, and did not forget him in the *Dunciad*. Philips supported the government in the columns of the *Free-thinker*, and was rewarded by being made secretary to Archbishop Boulter in Ireland. Later he sat for Armagh, acted as secretary to the Lord Chancellor and judge of the Prerogative Court, and after his patron Boulter's death returned to London, and died in 1749. Of his plays, *The Distress'd Mother* (1712)—an adaptation from Racine's *Andromaque*—was warmly praised in the *Spectator*; *The Briton* and *Humphrey, Duke of Gloucester* lived only long enough to be damned. His *Pastorals* are vigorous and easy yet graceful verse, but lack the charm that belongs to Gay, whose *Shepherd's Week* was really written at Pope's instigation to take Philips off. Some of his odes, addressed to children, and written with simplicity of diction, earned him from Henry Carey the nickname of 'Naumby-Famby,' and thus brought a new word into the English language.

See Johnson's *Lives* and Pope's Correspondence in Elwin and Courthope's edition.

Philips, or PHILLIPS, EDWARD, the elder of the two nephews brought up and educated by Milton, the sons of his sister Anne, whose husband Edward Phillips held a government office in Chancery and died in 1631, leaving two sons to Milton's care. Edward Philips was born in 1630, and became a student of Magdalen College, Oxford, but left in 1651 without taking a degree. In 1663 he was tutor to the son of John Evelyn at Say Court in Essex. He is mentioned in Evelyn's Diary as 'not at all infected by Milton's principles,' yet certainly he entertained a great respect and admiration for his uncle, and not only extolled Milton in his *Theatrum Poetarum* as 'the exacter of heroic poets,' 'who hath revived the majesty and true decorum of Heroic Poesy and Tragedy,' but has left us a valuable though short and fragmentary *Life* of the poet. This was originally prefixed (1694) to a translation of Milton's *Letters of State*, but is now most accessible in Godwin's *Lives of E. and J. Philips* (1815, pp. 350-383), and is, as Johnson says, 'the only authentic account of Milton's domestic manners.' Of his numerous works may be mentioned a complete edition (the first) of the *Poems of Drummmond* of Hawthornden (1656); *New World of English Words* (1658), a kind of dictionary, which went through several editions; the *Continuation of Baker's Chronicle of the Kings of England* (1665); *Theatrum Poetarum, or a Complete Collection of the Poets* (1675); the *Tractatus de Carmine Dramatico Poetarum* in the 18th edition of Buchler's *Thesaurus* (1679); and *Tractatus de Lingua Latina* (1682). Milton, says Aubrey, made his nephews songsters, and sing from the time they were with him; verses by both are found in *Ayres and Dialogues for One, Two, and Three Voices*, by Henry Lawes (1653). Edward is thought to have died not long after the publication of the *Letters of State*, perhaps in 1696.

Philips, JOHN, Milton's younger nephew and more peculiar charge, born in 1631, was, like his brother Edward, educated by his uncle, and frequently acted as his amanuensis. It may be supposed that Milton had formed a high opinion of his literary capability, since he entrusted to John rather than Edward the writing of the *Responsio ad Apologiam pro Rege et Populo Anglicano* (1652), himself correcting it with the utmost care. But if John was Edward's superior in ability, he was greatly his inferior in character, and persistently displayed an unnatural animosity to his uncle and benefactor. His next work was *A Satyr against Hypocrites* (1655), a bitter anti-Puritan poem and attack on Cronwell, written with considerable

talent, but in a strain of coarse buffoonery. Some-what in the style of Chancer, he describes a Sunday in Cromwell's time, a christening, and a Wednesday fast with the extravagant supper at night. This production was frequently reprinted, and must have caused Milton no small disappointment and annoyance. In 1660 John amused himself and the world with his *Monticlon* or the *Prophetical Almanac*, a low, scurrilous work, which was, however, extremely successful; he was also a most industrious translator, and in little more than a year (1677) published three large folio translations, *Almahide*, from the French of Madame de Scudéry, on which was founded Dryden's tragedy, *The Conquest of Granula*; Calprenède's *Pharamond*; and Tavernier's *Voyages*. Philips wrote many scurrilous pamphlets, and died in 1706. See Godwin, *Lives of Edward and John Phillips* (1815).

Philips, JOHN, described on the monument in Westminster Abbey erected by Sir Simon Harcourt to his memory as a second Milton. He was the author of three very popular poems, *The Splendid Shilling*, a burlesque of Milton's manner; *Cider*, an imitation of Virgil; and *Blenheim*, a Tory celebration of Marlborough's great victory. He was born in 1676, but, curiously enough, was registered at Winchester as five years, and at Christ Church, Oxford, as six years younger than he really was. He died in 1709, and was buried in the cathedral at Hereford.

Philips, KATHERINE, 'the matchless Orinda,' was born the daughter of a respectable Presbyterian London merchant, on New-year's Day 1631. A precocious child, she early became strongly royalist in feeling, and in her seventeenth year she married a worthy Welsh gentleman, James Philips of Cardigan Priory. Her earliest poem was an address to Henry Vaughan the Silurist, on the appearance of his *Olur Iserenus* (1651). About the same time she seems to have assumed her melodious *nom-de-plume* of Orinda, having formed among her neighbours of either sex a Society of Friendship, the members of which must needs be re-baptised—the Ladies as Lucenia, Rosania, Regina, Valeria, Polyerite; the gentlemen as Palamon (Jeremy Taylor), Silvander, Antenor (her own husband), and Poliarchus (Sir Charles Cottelet, her greatest friend, her forty-eight *Letters* to whom were published in 1705). Our earliest sentimental writer, Orinda, has tears at will even for the marriages of the lady-members, which she resents as outrages on the sufficiency of friendship. Yet she was a worthy woman and a good wife, and deserved the honour of a dedication from Jeremy Taylor (*Discourse on the Nature, Offices, and Measures of Friendship*, 1659). She went to Dublin in 1662, and here Roger, Earl of Orery, and the rest gave her a flattering reception. On a visit to London she caught smallpox, and died at thirty-three, 22d June 1664. At Dublin she translated Corneille's *Pompeé*, and in her last year the greater part of his *Horace*. Her poems were surreptitiously printed at London in 1663, but an authoritative edition was issued in 1667. Her poetry has long since been forgotten despite the eulogiums of contemporary praise from Cowley and others. Keats found her poems in 1817 while writing *Eudymion*, and in a letter to Reynolds speaks of them as showing 'a most delicate fancy of the Fletcher kind.'

See Gosse, *Seventeenth Century Studies*, and text in Saintsbury, *Caroline Minor Poets* (vol. i. 1905).

Philips, STEPHEN, poet and dramatist, son of the Precentor of Peterborough Cathedral, was born in 1864 at Somerton, near Oxford. After studying at Cambridge, he did some acting and army tutoring, but then turned to literature, drawing critical notice by his striking *Christ in Hades* (1896) and

collection of *Poems* (1897). His best plays, in classical style, were *Paolo and Francesca* (1899), *Herod*, *Ulysses*, *The Sin of David*, *Nero* (1906). His *New Inferno*, a blank verse allegory, appeared in 1910. He died at Deal in 1915.

Phillipstown, a market-town of King's County, Ireland, 8 miles E. of Tullamore and 38 miles W. of Dublin, takes its name from Queen Mary's consort, Philip of Spain. Pop. 660.

Philistines (Heb. *Pelishtim*; Gr. *allophuloi*, 'strangers'), a people mentioned in the Bible as being in frequent contact with the Jews, who gave their name to the country called Palestine, and who belonged to a group of maritime tribes inhabiting the Mediterranean coast-lands, including the islands of Cyprus and Crete, possibly also Sardinia and Sicily, the fringes of Asia Minor and the Aegean countries. Until quite recent times very little was known of the Philistines, and although much indeed still remains to be learnt about them, nevertheless the reader is cautioned against books written on this subject prior to the archaeological discoveries of the present century. It is particularly by the latest results of Egyptian and Hittite research that the problem of the Philistines must be approached. It would appear probable that the first Philistine settlement in Palestine is to be dated about 1190 B.C., during the reign of Ramesses III., about the time of the Trojan War, just after the accession of Agamemnon at Mycenae and the conclusion of the second war of Argos against Thebes. The exodus of the Israelites from Egypt is generally placed at 1240, or about half a century before the Philistine settlement, and in consequence of the martial reputation which the Philistines bore, the circuitous route through the wilderness was taken by Moses (Exodus, xiii. 17). Yet the circumstance presents certain difficulties which yet await solution.

It is a noteworthy fact that the Old Testament narrative invariably represents the Philistines as totally distinct from the Semitic inhabitants of Palestine, not only because they were uncircumcised, but generally because of their social, religious, and political organisation. The famous genealogical table in Genesis (x. 14) counts them among the Egyptian colonies (the 'Cushim, out of whom came the Philistines'); according to Amos, ix. 7, Jeremiah, xlvii. 4, and Deuteronomy, ii. 23, they came from Caphtor—formerly, from mere resemblance of the word, identified with Cappadocia. Others have, no less groundlessly, derived them from the Pelasgians. The tendency is to believe that the Philistines, who were undoubtedly immigrants, came from Crete, the collocation of Cherethites (Cretans) and Pelethites (2 Sam. viii. and xv.) favouring this view. Moreover, if the equation of Caphtor with Keftiu is somewhat doubtful on account of the final *r*, it is strengthened collaterally by the mention, in a hieratic school exercise-tablet (Brit. Mus. 5647) dating from the end of the 18th dynasty, of Akason as a Keftian name; this at once recalls the Philistine name Achish. All that is known of the Philistines points to a Cretan origin. In their civilisation there were Carian elements, and thus Minoan influence may have made its appearance in Palestine.

It is doubtful if Abimelech, king of Gerar (Gen. xxi., xxvi.), was king of this people or merely of the country afterwards Philistine; more probably the expulsion of the Danites (Judges, v. xviii.), presumably before the new invaders, marks their first appearance as aggressive enemies. They were subject to five princes, who ruled over the provinces of Gaza, Ashdod, Ascalon, Gath, and Ekron. They were so powerful at the time of Eli that they carried away the ark itself. Under Samuel their

rule was terminated by the battle of Mizpah. Saul was constantly engaged in warding off his new encroachments, and at Gilboa he and his sons fell in a disastrous battle against them. David succeeded in routing them repeatedly; and under Solomon their whole country seems to have been all but incorporated in the Jewish empire. The internal troubles of Judæa emboldened the Philistines once more to open resistance; but Hezekiah subdued their country with the aid of the Egyptians. The Assyrians afterwards took Ashdod; and in the time of the Maccabees the Philistines were Syrian subjects; by the time of Herod the name of the country had long been lost in that of Palestine. A civilised, agricultural, commercial, and warlike nation, they traded largely, and their wares seem to have been much sought after.

The power of the Philistines at the beginning of their history in Palestine is well illustrated by the Golénischef papyrus, which gives the account of an Egyptian envoy, Wen Amon, in the reign of Ramesses XII., his adventures at the court of Zakai Baul, Prince of Byblos, and his treatment by Philistine sailors. The narrative brings out clearly not only the decay which had overtaken Egyptian authority but the strength of the Philistines and other 'sea tribes.'

The Philistine language is non-Semitic. Until the Phœstos disk is deciphered, little can be stated with certainty, save that the word *seren*, o 'lord' (1 Kings, vii. 30; Jud. iii. 3), is definitely Philistine, and may be connected with the Greek *tyrannos*: Renan's list of Philistine words in the Hebrew Bible (*parbat*, submb, cf. *peribolus mekhonah*, *machina*; *mekkereth*, sword (?), *αδχαπα επιπτορ*, crown, capital; and *pilgresh*, concubine, *pillex*) is doubtful. The problems connected with the Philistine head-dress and the god Dagon are brilliantly discussed by R. A. S. Macalister (*vide infra*).

Finally, it should be observed that R. N. Salaman (*vide infra*) maintains a partial racial fusion between Philistines and Jews, resulting in the 'Pseudo-Gentile' type which is so common to-day among Jews.

The latest information and bibliographies may be found in R. A. S. Macalister, *The Philistines, their History and Civilisation*, Schweich Lectures for 1911 (Oxford, 1913); see also articles in *Encyc. Brit.* and *Jew. Encyc.*; *Camb. Anc. Hist.*, vol. ii. (Camb. 1924); the Golénischef papyrus appeared in *Recueil de Travaux relatifs à la phil. et à l'arch. égypt. et assyri.*, xxi. 74; R. N. Salaman, 'Racial Origins of Jewish Types', *Trans. Jew. Hist. Soc.* (London, 1922), and 'The Philistines', *Pal. Expl. Fund.*, *Quart. Statement* (Jan. and Apr. 1925).—German students call those who have ceased to be students, as well as non-students, tradesmen, &c., *Philister* or Philistines; hence the further sense of 'uncultured,' 'narrow-minded,' in which application the term has come to be used in Britain, especially through Matthew Arnold's influence.

Phillimore, SIR ROBERT JOSEPH, born 5th November 1810, studied at Oxford, and, after serving in the Board of Control, had a brilliant career at the bar. He sat in Parliament as a Whig from 1853 to 1857; and held in succession the offices of Advocate-general (1862, when he was knighted), Judge Advocate-general (1871), judge of the Archæes Court (1867-75) and of the High Court of Admiralty (1867-83). Made a baronet in 1881, he died 4th February 1885. His most important works are his *Commentaries upon International Law* (4 vols. 1854-61; 3d ed. 1879), and his *Ecclesiastical Law of the Church of England* (2 vols. 1873; suppl. 1876). His eldest son WALTER GEORGE FRANK PHILLIMORE, 1st Baron Phillimore (born 1845) issued a second ed. of *Ecclesiastical Law* (1895), a third ed. of vol. iv. of *International Law*, and wrote *Three Centuries of Treaties of Peace and*

their Teaching (1917). He was raised to the peerage in 1918.

Phillip, JOHN, R.A., was born, an old soldier's son, at Aberdeen on 19th April 1817. He was apprenticed to a painter and glazier, but in 1836 was sent by Lord Panmure to London, where he was ere long admitted to the schools of the Royal Academy. In 1838 he began to exhibit in the Academy Exhibition. Most of his early subjects were of Scottish character, such as a 'Scotch Fair' and 'Baptism in Scotland.' In 1851 he went to Spain in search of health. On his return he became noted as a painter of the habits and customs of the Spanish people, and was known as 'Spanish Phillip.' In 1857 he became A.R.A., in 1859 R.A. His main triumphs were in Spanish subjects, such as 'La gloria' (1864), and 'El Cigarillo' (1864). He twice again visited Spain, was in Italy in 1866, and died in London, 27th February 1867. He was a great colourist, and his light effects were broad and strong.

Phillipps, JAMES ORCHARD. See HALLIWELL-PHILLIPPS.

Phillipps, SIR THOMAS, antiquary and manuscript-collector, was born in 1792 at Manchester of an old Worcestershire family, and succeeded to the Middle Hill estates on his father's death in 1818. He was made baronet in 1821 and high-sheriff of Worcestershire in 1825. His famous collection of some sixty thousand manuscripts, largely mediæval, embraced specimens from all over Europe. He died at Cheltenham in 1872.

Phillips, WENDELL, abolitionist, was born 29th November 1811, at Boston, Massachusetts, the son of the first mayor of the city (1822). He graduated at Harvard with Motley in 1831, studied law there, and was called to the bar in 1834. But before clients came he had been drawn away from his profession to the real work of his life. A timely and important speech in Faneuil Hall in 1837 made him at once the principal orator of the anti-slavery party; and henceforth, until the president's proclamation of 1st January 1863, he was Garrison's loyal and valued ally, his lectures and addresses doing more for the cause than can well be estimated. He also championed the cause of temperance, and that of women, and advocated the rights of the Indians. In 1870 he was nominated for governor by the Prohibitionists and the labour party. He died 2d February 1884. His speeches and letters were collected in 1863 (new ed. 1884); and there are Lives by Austin (Boston, 1888) and Sears (New York, 1900).

Phillipsburg, a city of New Jersey, on the Delaware River (crossed by two railroad bridges), opposite Earton, at the western terminus of the Morris Canal, and 73 miles W. of New York by rail. It contains foundries and manufactures mining-machinery, pumps, &c. Pop. 17,000.

Phillpotts, EDEN, born in India in 1862, was educated in Plymouth, and was for ten years a clerk. Turning to literature, he made his name by *Children of the Mist* (1898), and other realistic novels, the favourite scene of his books being Dartmoor. His more important publications are *The Human Boy* (1899), *Sons of the Morning* (1900), *Widcombe Fair* (1913), *The Secret Woman* (dramatised 1912), *St George and the Dragons* (a play, 1919), and some collections of verse.

Phillpotts, or PHILPOTTS, HENRY, was born at Bridgwater, 6th May 1778, studied at Corpus Christi College, Oxford, and was elected Fellow of Magdalen in 1795. He became prebendary of Durham in 1809, Dean of Chester in 1828, and Bishop of Exeter in 1831. A zealous Tory, an extreme High Churchman, and combative by disposition, he

was ever the foremost in opposition to measures of reform, and his name would survive if only for his prolonged but unsuccessful refusal to institute George Gorham (q.v.) for not believing in baptismal regeneration. Yet if he was narrow he was devoted and sincere, his standard of a bishop's duties was an unusually high one, and he was much beloved throughout his diocese. He died near Torquay, 18th September 1869.

Philo Byblius. See PHENICIA.

Philoctetes, a famous archer, the friend and armour-bearer of Hercules, who bequeathed him his bow and poisoned arrows. As one of the suitors of Helen, he led seven ships against Troy; but being bitten in the foot by a snake (or, according to one story, wounded by his own arrows), he fell ill. As his wound gave forth an unendurable stench, the Greeks left him on the island of Lemnos, where for ten years he spent a miserable life. But an oracle declared that Troy could not be taken without the arrows of Hercules, so Odysseus and Neoptolemus were despatched to bring Philoctetes to the Greek camp; where, healed by Asclepius or his sons, the restored hero slew Paris, and helped powerfully in the taking of Troy. After the war he settled in Italy. A play of Sophocles is named from him.

Philodendron, a genus of Araceæ, comprising over 200 species mostly of climbing plants (hence the name) in tropical and subtropical America. Many of them play a great part in the local pharmacopœia. *P. bipinnatifidum*, in Brazil called *banana de macico* (monkey banana), has berries which are liked by man too. *P. Sonderianum*, var. *Missionum*, an epiphyte of Misiones province, Argentina, has aerial roots several yards long, from whose bark are made ropes that will not rot in water. Fibre from the petioles is also made into ropes.

Philo Judæus, the Philosopher, was born at Alexandria, most probably about 20-10 B.C. Belonging to a wealthy family—his brother, according to Josephus, was the alabarch or arabarch Alexander—he received the most liberal education; and such was his zeal for learning that at a very early age he had passed through the ordinary course of Greek studies. Although every one of the different free sciences and arts included in the *Ennechika*, he says, attracted him like so many beautiful slaves, he yet aimed higher, to embrace the mistress of them all—Philosophy. Metaphysical investigation was the only thing which, he tells us, could give him anything like satisfaction or pleasure. He was intimately acquainted with Plato, the Greek tragedians, and Homer, and he speaks with the warmest praises of the Stoics and the Pythagoreans. With these and especially with Plato his affinities are closest—an old proverb runs: ἡ Ἰλλυριανὸν φιλοσοφία ἢ Φίλων παρὰ τω Πλάτῳ. Yet with all his Greek culture he remained a Jew, holding Jewish philosophy as the highest wisdom, the divine revelation given to Moses as the source of all true knowledge in religion. He had completely mastered the literature of his nation, but, strange to say, was by no means a profound Hebrew scholar. When over fifty years of age he went to Rome as the advocate of his Alexandrian brethren, who had refused to worship Caligula in obedience to the imperial edict. His *De Legatione ad Cæsarem* gives a vivid account of this embassy. Of his life we know little except what is recorded above, and that he once went to Jerusalem. His second mission to Rome, to the Emperor Claudius, on which occasion Eusebius reports that he made the acquaintance of the apostle Peter, is doubtful.

The religious and philosophical system of Philo, however, is most minutely known, and deserves the

most careful study on account of the vast influence which it has exercised both on the Jewish and Christian world. To understand his system aright it will be necessary to recall to memory the strange mental atmosphere of his day. The Alexandrines had endeavoured to make Judaism palatable to the refined Greeks, by proving it to be identical with the grandest conceptions of their philosophers and poets, and had quite allegorised away its distinctive characteristics. Philo was the first man who, although himself to a great extent imbued with allegorising tendencies, made a bold and successful stand against a like evaporation of the revealed religion of his fathers; which, indeed, in many cases had led people to throw off its yoke also outwardly. Himself a most zealous champion of Judaism, his bitterness knows no bounds in rebuke of those co-religionists who tried to defend their secret or overt apostasy by scoffing at the Law itself, who were 'impatient of their religious institutions, ever on the lookout for matter of censure and complaint against the laws of religion, who, in excuse of their ungoverned, thoughtlessly argue all manner of objections.' He cannot understand how Jews, 'destined by divine authority to be the priests and prophets for all mankind,' could be found so utterly blind to the fact that that which is the position only of a few disciples of a truly genuine philosophy—viz. the knowledge of the Highest—had by law and custom become the inheritance of every individual of their own people; whose real calling, in fact, it was to invoke the blessing of God on mankind, and who, when they offered up sacrifices 'for the people,' offered them up in reality for all men.

To Philo the divinity of the Jewish Law is the basis and test of all true philosophy. Although, like his contemporaries, he holds that the greater part of the Pentateuch, both in its historical and legal portions, may be explained allegorically—nay, goes so far even as to call only the Ten Commandments, the fundamental rules of the Jewish theocracy, direct and immediate revelations, while the other parts of the Book are owing to Moses—he yet holds the latter to be the interpreter specially selected by God, to whose dicta in so far also divine veneration and strict obedience are due; and again, while admitting that many explanations of a metaphysical nature may be given to single passages, yet demands in general that their literal meaning shall not be tampered with. This literal meaning, according to him, is the essential part, the other explanations are mere speculation—exactly as the Midrash and some Church Fathers hold. At the same time it is true that, without denying the literal meaning, again and again he puts forward the allegorical meaning as the one really divine, and indeed sometimes he treats the literal meaning as absurd. Only the allegorical method in his hands differed in so far from that of his contemporaries that to him these interpretations—for which he did not disdain sometimes even to use the numbers symbolically, or to derive Hebrew words from Greek roots, and the like—were not a mere play of fancy, in which he could exercise his powers of imagination, but, to a certain extent, a reality, an inner necessity. He clung to philosophy, as combined with the Law. If the former could be shown, somehow or other, to be hinted at in the latter, then only he could be that which all his soul yearned to be—viz. the disciple of both: a Greek, with all the refinement of Greek culture, and a Jew—a faithful, pious, religious Jew. Nay, he even urged the necessity of allegory from the twofold reason of the anthropomorphism current in Scripture and from certain apparent superfluities, repetitions, and the like, which, in a record that emanated from the Deity, must needs have a special meaning of their own which

required investigation and a peculiar interpretation. Yet this fanciful method never for one moment interfered with his real object of pointing out how Judaism most plainly and unmistakably was based upon the highest ethical principles.

His writings develop his ideas and his system in the two directions indicated. In that division of his writings principally which treats of the Creation (*ἀσμοπόρετα*) he allows allegory to take the reins out of his hands; in that on the Laws (*νόμοι*), on the other hand, he remains remarkably sober and clear, extolling the Mosaic legislation throughout at the expense of every other known to him. In a very few instances only is he induced to find fault, or to alter slightly, by way of allegory, the existing ordinances.

His idea of God is intended to be in the highest degree philosophical, though its religious significance is never lost sight of. God alone is the real Good, the Perfect, the final cause of all things, which ceaselessly flow outwards from Himself. God is only to be imagined as the primeval light, which cannot be seen by itself, but which may be known from its rays that fill the whole world. Being infinite and uncreated, He is not to be compared with any created thing. He has, therefore, no name, and reveals Himself only in designations expressive of this 'inexpressibility,' such as 'the Place' (the Tabernical *Μακὼν*), because He comprises all space, and there is nothing anywhere besides Him. He is better than Virtue and Knowledge, better than the Beautiful and the Good (*καλοκἀγαθία*), simpler than the One, more blissful than Bliss. Thus He has properly speaking no quality, or only negative ones. He is the existing Unity or Existence itself (*ὁ ὢν*), comprised in the unpronounceable Tetragrammaton. As Creator, God manifests Himself to man, and in this phase of active revelation of God, which is as natural to Him as burning is to the heat, and cold to the snow, may be distinguished two distinct sides or essential properties, the Power and the Grace, to which correspond the two Scripture names of Elohim and Adonai. The Power also gives the laws and punishes the offender; while the Grace is the beneficent, forgiving, merciful quality. Yet, since there is not to be assumed an immediate influence of God upon the world, their respective natures being so different that a point of contact cannot be found, an intermediate class of beings had to be created to stand between both, through whom He could act in and upon creation—viz. the spiritual world of ideas, which are not only 'Ideals,' or types, in the Platonic sense, but real, active powers (*δυνάμεις*), surrounding God like a number of attendant Beings. They are His messengers, who work His will, and by the Greeks are called good *daimons*, by Moses *angels*. There are very many different degrees of perfection among them. Some are immediate 'serving angels'; others are the souls of the pious, of the prophets, and the people of Israel, who rise higher up to the Deity; others, again, are the heads and chief representatives of the different nations, such as Israel does not need, since they conceive and acknowledge the Everlasting Head of all Beings Himself. Collectively the Powers are used as equivalent to the nature or essence of God—his ideas or thoughts dominating and informing the universe; yet they are far from being substitutes for God. Zeller maintains that in Philo's doctrine of the Powers two representations cross each other—the religious notion of person, and the philosophical of impersonal, mediators. Edersheim also asserts that here Philo's philosophy and theology are hopelessly at issue, the *δυνάμεις* being undoubtedly represented as *hypostases*, while yet they have no true personal subsistence. Dr Drummond refuses to admit that

Philo imputed personality to the Powers, or that he identified them with the angels. Schürer maintains that we cannot deny definitely the personification of the *λόγοι* or *δυνάμεις*, since Philo conceived of them both as independent hypostases and as immanent determinations of the Divine existence.

The *Logos*, or Divine Reason, comprises all these intermediate spiritual powers in His own essence. It is the universal idea, the one supreme and all-embracing thought which unifies everything into a real cosmos—a property of God, and the representative of God in His relation to the created world. As such the *Logos* is the highest of the angels, the Beginning, the Name, the Word, the Primeval Angel, the first-born son of God, the second God (*δεύτερος θεός*, in opposition to *ὁ θεός*). As the expressed Thought of God it has a twofold aspect regarded as the *uttered* and the *unuttered* *Logos*, although this is not formally expressed by Philo. It becomes objective in the harmonies of the created world, and stands distinct from the same Thought when hidden in the silent depths of God, and known only to His omniscience. The *Logos* formed the world out of chaotic matter, regarded as a mass occupying space, and now considered as the *μή ὄν* of Plato, again as the *oekia* of the Stoics. Man is a microcosm, a little world in himself, a creation of the archetypal *Logos*, through whom he participates in the Deity, or, as Scripture has it, 'he is created in the image of God.' He stands between the higher and lower beings—in the middle of creation. The ethical principles of Stoicism Philo identified with the Mosaic ethics, in which the ideal is most exalted moral perfectibility or sanctity, and man's duties consist in veneration of God, and love and righteousness towards fellow-men. Philo holds firmly the belief in immortality. Eternity is the motionless duration of unalterable being; time but the moving succession of ever-shifting phenomena. Man is immortal by his heavenly nature; but as there are degrees in his divine nature, so there are degrees in his immortality, which only then deserves this name when it has been acquired by an eminence of virtue. There is a vast difference between the mere living after death, which is common to all mankind, and the future existence of the perfect ones. Future recompense and punishment are not taken by him in the ordinary sense of the word. Virtue and sin both have all their rewards within themselves; but the soul, which is 'pre-existing,' having finished its course in the sublunar world, carries this consciousness with it in a more intense and exalted manner. Paradise is Oneness with God; there is no hell with bodily punishments for souls without a body, and no Devil in the Philonic system. Dr Drummond has succeeded in proving against Dalme and others that matter, though eternal, is purely passive, and not itself necessarily evil in Philo's teaching. The source of the imperfection is not in the material as opposed to the spiritual, but in the phenomenal as opposed to the eternal. The human *πνεῦμα* is itself an emanation from Deity, subject meantime to the bondage of sense, and the loftiest principle of ethics is the utmost possible renunciation of sensuousness. The direct vision of God is possible only for those souls which have been lifted out of themselves and illumined by renunciation and severe purity. And transcending this ecstasy is the complete deliverance from the body beyond the gates of death, when the soul that has freed itself in life from the bondage of sense returns again to its original condition as pure spirit.

Philo's Messianic notions are vague in the extreme, and he partly even interprets certain scriptural passages alluding to some future Re-

deemer as referring to the soul. Yet he indicates his belief in a distant time when some hero will arise out of the midst of the nation who will gather all the dispersed together; and these, purified by long punishments, will henceforth form a happy, sinless, most prosperous community, to which all the other nations will be eager to belong. Still the Messianic hope is very obscure, and Dähme's identification of the Logos with the Messiah is indefensible.

We have only been able to indicate, in the slightest of outlines, the principal features of Philo's theology and philosophy, without endeavouring to follow any one of the manifold systematic schemes into which his scattered half-obscure dicta have been pressed. His method of exegesis and the main elements of his religious philosophy passed into the Christian church, and exercised a powerful influence over its thinkers. Nor can Philo ever lose his importance in the history of thought as the earliest eclectic religious philosopher, the first to construct a real philosophy of religion, in which were harmonised the rational and the irrational—the results of speculative thought with the suppositions of a supernatural revelation.

Philo's writings are numerous, and their arrangement presents no small difficulty to the student. Many of his writings in the list given by Eusebius (*H. E.* ii. 18) are lost, but the bulk even of these have been preserved in the Fathers and early Christian writers, like Eusebius, who quote Philo to an enormous extent. Many detached portions have also been preserved in the *Florilegia* and similar compilations of the earlier Christian Paraphrasts. The first and very imperfect edition of the Greek text was that published by Turnebus (Paris, 1552), containing only thirty-nine treatises. This was followed by those of Thomas Manger (2 vols. folio, Lond. 1742) and Holtz (Leipzig, 1851). The *Libellus de Opificio Mundi* was edited by Leop. Colln in 1889 as a specimen of a projected edition; Colln and P. Wendland's critical edition of Philo (Berl. 1896-1902) is now the standard one. Some writings of Philo preserved only in Armenian have been published in Latin translations by J. Bapt. Achier (Venice, 1822, 1826); and Greek portions of greater or less extent have been given by Mai, Grossmann, Tischendorf, Cardinal Pitra, and Professor J. Rendel Harris (Cambridge Press, 1886). The more recently collected materials are contained in the hand edition of C. E. Richter (8 vols. Leip. 1828-30) and the Tachnütz stereotype edition (8 vols. Leip. 1851-53). See the brief account of each book in Schurer's *Hist. of the Jewish People* (di. 2, vol. iii. 1886) in Clark's translation. An important contribution to Philo bibliography is that by L. Maassabian (Paris, 1889). There is an Eng. trans. by C. D. Yonge in Bohn's 'Eccles. Library' (4 vols. 1854-55).

More than three-fourths of what has come down to us from Philo consists of three chief works on the Pentateuch: (1) *Ἐξηγήματα καὶ διόριστοι* (*Questions et Solutions*)—in Armenian a short explanation of Genesis and Exodus in question and answer; (2) *Νόμων ἑρμηνεία*, a large allegorical commentary on Genesis, in which the history is interpreted as a system of psychology and ethics, itself filling almost the whole of Mangey's first volume, and consisting of a series of sixteen special treatises; (3) a group of compositions intended as an *Exposition of the Mosaic Legislation for non-Jews*, and falling naturally into three divisions—an Account of the Creation (*κοσμοποιία*, *De Opificio Mundi*), the Biographies of Virtuous Men, and the Legislation proper. Besides these have been preserved, either entire or in fragments, the following works: *Ἐπεὶ βλοῦ Μωυσέως* (*Vita Moses*), *Ἐπεὶ τοῦ πάντα σπουδαῖον εἶναι ἐκείθεν* (*Quod omnis probus liber*), *Εἰς Φάλακρον* (*Adversus Flaccum*) and *Ἐπεὶ ἀπερὶ τῶν καὶ προσέλας πρὸς τὸν Ἰάβιν* (*De legatione ad Cuium*), *Ἐπεὶ πορτοίας* (*De Providentia*), *Ἀλέξανδρος ἡ περὶ τοῦ λόγου ἔχων τὰ λόγια ἴδω* (only in Armenian), *Ἐρωτητικά* (known only from Eusebius), and *Ἐπεὶ ἰουδαίων*.

Other works now generally regarded as spurious are *De Incorruptibilitate mundi*, *De Mundo*, and *Interpre-*

tatio Hebraicorum nominum. The Philonic authorship of the *De Vita contemplativa* was attacked by Lucius (*Die Therapeuten*, 1879), but defended by Edersheim in Smith's *Dict. of Christ. Biography*, and with great ingenuity by F. G. Conybeare in his admirable edition of the text (1895).

See H. C. Kyle, *Philo and Holy Scriptures* (1895); Herriot, *Philon le Juif* (Paris, 1898); Gfroer, *Philo und die Alexandrinische Theosophie* (Stuttgart, 1831); Dähme, *Die Jüdisch-Alexandrinische Religions-Philosophie* (Hall, 1834); Keferstein, *Philo's Lehre von den göttlichen Mitteln* (Leip. 1846); Siegfried, *Philo von Alexandria als Ausleger des Alten Testaments an sich selbst und nach seinem geschichtlichen Einfluss betrachtet* (Jena, 1875); Zeller, in part iii. div. 2 of *Die Philosophie der Griechen* (3d ed. 1881); Edersheim's *Life and Times of Jesus the Messiah* (2 vols. 1883); Principal Drummond's admirable *Philo-Judæus, or the Jewish-Alexandrian Philosophy in its Development and Completion* (2 vols. 1888); L. Colln in *Hermes*, xxxviii. (1903) and xliii. (1908); C. G. Montefiore, 'Florilegium Philonis', *Jew. Quart. Rev.*, vii.; the following articles in *Jew. Quart. Rev.*, F. C. Conybeare ('Philo concerning the Contemplative Life'), vii.; 'The Philon. Text of the LXX.', v. viii; L. Colln, v. x.; S. Krauss, x.; J. H. A. Hart, xvii., xx.; an admirable study (and bibliography) is that of N. Bentwich, *Philo-Judæus of Alexandria* (Philad. 1910). See also H. I. Bell, *Jews and Christians in Egypt* (Brit. Mus. 1924). I. Abrahams on the permanent value of Philo in *Permanent Values* (Oxford, 1921). On Philo and the Jewish *Halakha* see B. Rittor, *Philo* (Leipzig, 1879). The admirable essay on *Hellenistic Contributions by C. G. Montefiore*, in his *Old Testament and After* (Lond. 1923), should be carefully studied. The Oxford Lectures (1925) on Philo by E. R. Bevan are summarised in his essay on 'Hellenistic Judaism,' in the *Legacy of Judaism* (Oxford, 1926), and should be consulted as the most recent contribution to the subject and the best treatment of existing information. See also articles in *Jew. Encyc.*, Hastings's *E. R. E.*, and *Encyc. Brit.*

Philology. The meaning of this term has varied enormously. As we find it first employed by Plato, it meant the love of discussion, limited practically to the moral and social questions in which Plato delighted; and the method of such discussion was the Socratic one. At Alexandria the 'philologist' was busied with all the knowledge of his day brought together for the first time in the great library of the Ptolemies. Thus, Eratosthenes, who applied this term to himself, was specially famous as a writer on astronomy. But the great scholars of Alexandria devoted themselves with especial eagerness to the study of the older Greek literature. Men like Zenodotus and Aristarchus compared the numerous MSS. of Homer, selected the best texts, made lists of difficult words, called *glossæ*—the earliest dictionaries—and were the founders of the science of criticism by establishing canons on which they rejected what they deemed spurious in the copies before them. Two centuries later at Rome Cicero, who uses the word not infrequently in his letters, applies it to study in general. But ever after the Alexandrian time 'philology' was essentially the intelligent critical study of the traditional learning of the past. It widened again at the revival of learning to include the study of grammar, rhetoric, poetry, archæology—in a word, all the 'humane' studies. And this wider sense clung to the word. Johnson in the 18th century defines a philologist as 'one whose chief study is language, a grammarian, a critic.' Yet Watts, whom he quotes as one of his authorities for the use of the word, says that 'studies called philological are history, language, grammar, rhetoric, poesy, and criticism.' In fact philology was the study which interpreted the best writings; and these writings were Greek and Latin; and in these languages were to be found the most noteworthy speculations on all matters of human interest. So philology had its special and its wider sense.

The work of the critical scholar of the present day has been widened to a degree which could not have been realised before the 19th century. First, the art of interpretation has been developed; the old storehouses of MSS. have been more fully searched; the principles of paleography are more widely known, so that we have many more scholars capable of dealing at first hand with MSS., of deciding upon their age, origin, and relative value. The sister-art of epigraphy, which deals with inscriptions, has ever-increasing material to work upon. Secondly, the science of archaeology has been almost re-created. Explorations in all parts of the Hellenic world—Attica (especially the Acropolis at Athens), Delphi, the Peloponnese, Cyprus, Crete, and Asia Minor—have profoundly affected our ideas of Greek art, both plastic and constructive. The long-continued excavations at Pompeii have shown us the domestic life of the 1st century in the most minute detail. There can be no doubt that we have yet much to learn, and that the zeal of modern students will be equal to the task. Again, historical inscriptions and coins have corrected and supplemented the statements of ancient writers, and have often given us unexpected and perfectly trustworthy information as to periods unrepresented in any literature. These and other auxiliary sciences have given new life and meaning to the scholar's work. They make it at once more satisfying and more difficult: there is so much more to be known. Formerly a really great scholar could master the whole domain of knowledge; now every man must depend for something on the labours of others.

The study of philology, especially the study of grammar, after it was transplanted from Alexandria, flourished at Rome in the imperial time. It lingered on at Constantinople till the line of great grammarians ended in Priscian; while lexicography culminated later in the work of Photius and of Suidas. But it was in Italy that the study of antiquity became again a living thing: Italians in the 14th and 15th centuries discovered in Italy, Germany, and France works of the greatest Roman writers, such as Cicero and Lucretius, which had remained for generations buried in convents; it was to Italy that learned Greeks, especially after the sack of Constantinople, came to teach the Greek language at Florence and at Venice, and brought with them the MSS. of Thucydides and of Plato, to be translated by Valla and by Ficinus; and it was in Italy that the results of their labours were first published to the world at large by the great houses of the Manucci and the Giunta. But with the exception of Faerno Italy had no great scholar. Yet by its connection with France it produced scholars in northern Europe. Budé was secretary to Louis XII., whose main interests were in Italy; Laubain visited Rome and Venice before he became the editor of Horace, of Lucretius, and of Cicero; while Muret, though born near Limoges, lived and worked at Rome from 1559 to his death in 1585, and at Rome he lodged for two years the young Joseph Scaliger, destined to become the foremost of European scholars. Italian by descent, but born in France, where he edited his Manilius and wrote his *De Emendatione Temporum*, the first great work in historical criticism, he was led by his conversion to Protestantism eventually to retire from France to Leyden, where he ended his days, the dictator of the world of letters. Isaac Casaubon, a leader in exegesis, as Scaliger was in criticism, though born at Geneva, was the son of a French Huguenot refugee, and in France he lived during the greater part of his life, till like Scaliger he found a securer home elsewhere—in Protestant England. Justus Lipsius, the third great scholar of the day, was a Belgian, professor successively at

Jena, at Leyden, and at Louvain; he also had travelled in Italy.

Of the members of the older German school the most famous was Erasmus, by birth a Hollander but the centre of a band of able scholars at Basel where he spent the last sixteen years of his life well known in England, and for a short time professor at Cambridge, a man of vast learning, but not a master in criticism, 'the man of letters, the first who had appeared in Europe since the fall of the Roman empire' (Mark Pattison). He lived some three years in Italy, but gained, as he thought nothing from it. Able scholars were Camerarius professor at Leipzig, and Gruter of Antwerp, the first great collector of Greek and Latin inscriptions. For different reasons France and Germany ceased to be the nurse of scholarship in the 17th century. The reign of Louis XIV. fostered modern rather than ancient literature; and Germany was the scene of furious war. But Scaliger's influence lived on in Holland. At Leyden, where he died, lived Daniel Heinsius and his son Nicolas, Gronovius (Gronovius), conspicuous for his skill in appreciating MSS., and Cluver (Cluverius), the first great writer on geography. At the same time Graef (Graevius) was editing Cicero at Utrecht. Some what later in England lived the first of English scholars, Richard Bentley, in frequent correspondence with Dutch scholars, but owing nothing to them, a man whose astounding critical power could not always save him from errors due to his self-confidence. The only other Englishman whose fame, like Bentley's, has steadily grown with time was Richard Porson, professor of Greek at Cambridge at the end of the 18th century. Distinguished names in the school of Holland in the 18th century are Heinsius and his pupils Ruhnken and Valckenaeer. In Germany we find Ernesti at Leipzig, the editor of Cicero; his scholar, Heyne, the founder of the school of Göttingen; Reiske of Leipzig, skilled not only in Greek and Latin, but also in Arabic, whose edition of the Greek orators is still in use; Winckelmann, the first great writer on ancient art; Wolf, professor at Halle, who is best known as the great Homerist critic, but whose general power and method almost entitle him to a place by the side of Scaliger and Bentley. Scholars of a later date are Immanuel Bekker, professor at Berlin, editor of Plato, Thucydides, the orators, and Aristophanes; Godfrey Hermann, a scholar of unusual breadth, whose fame rests securely upon his work on Æschylus; Boeckh, the editor of Pindar and of the *Corpus* of Greek inscriptions; Welcker, professor at Bonn, the first who combined the study of Greek art, literature, and mythology; K. O. Müller, whose services to the study of ancient history were cut short by his premature death; F. Ritschl, professor at Bonn, the restorer of the text of Plautus, as Lachmann at Berlin was the restorer of Lucretius; H. A. J. Munro of Cambridge, the inheritor of Lachmann's labour on Lucretius; Madvig the Dane, a Latin scholar of eminent acuteness; and Cobet, in whom the critical power of Holland seemed to be renewed again. To the end of the century belong Böhler of Bonn, editor of Petronius; R. C. Jebb of Glasgow and Cambridge, editor of Sophocles and Bacchylides; Ingram Bywater of Oxford, the Aristotelian scholar. (The fullest and best account of the history of classical philology is to be found in Sir J. Sandys' *History of Classical Scholarship*, 3 vols. 1903-8.)

In the 19th century, however, the term 'philology' came to be more frequently applied to *Comparative Philology*, which is a subdivision of the more general term, and grew out of the older sense of the word 'philology.'

Comparative philology has taken the place of such terms as 'linguistics' or the 'science of lan-

guage.' Either of these terms would have been more precise, but 'linguistics' has never been popular, and 'the science of language' has for some reason been regarded as cumbersome, although it was employed in Max Müller's famous lectures at the Royal Institution in 1861 and 1864. The origin of the term was the observation that groups of languages can be compared together in detail. In this way their structure and history could, to a large extent, be illustrated, and the discovery of the value of comparison laid the foundation of the whole modern structure of the science of language. In earlier centuries, when scholars went further in the investigation of their own language, or of Latin and its relation to Greek, which was a favourite theme of research, they did not think of comparing a number of languages together and ascertaining what relations existed between them.

In the Middle Ages it was generally assumed that the dispersion of peoples at the Tower of Babel was the origin of the difference between the known languages of the world, and consequently it was taken for granted that Hebrew was the original language from which all others had, in different degrees, become corrupted. There are several stories handed down, for example in ancient times by Herodotus of Psammethichus, King of Egypt, and in later times of Akbar in India, and of James IV in Scotland, who are reported to have made experiments in order to ascertain what the original language was. According to Herodotus (ii. 2) King Psammethichus entrusted two newly-born infants to a shepherd, with instructions that nobody was to be allowed to talk to them. They were to be kept entirely isolated, with no living creatures in the neighbourhood but the goat that supplied them with milk. After a time the children were reported to have uttered the word *bekos*, which, after much research by Egyptian scholars, was pronounced to be the Phrygian word for 'bread.' It is curious that it did not occur to Herodotus that if the Greek ending *-os* were left off, the word *bekos* was simply the cry of the goats, *bek*. King James IV. of Scotland in the same way isolated children with a dumb nurse upon the island of Inchkeith in the Firth of Forth. Lindsay of Pit-scottie, who relates the story, says that after a time the children pronounced sounds which were declared by the learned to be good Hebrew, but the historian himself pointedly remarks that he has no personal knowledge of the facts, and relates them only by 'the author's rehearse.'

Jesuit missionaries in India had observed similarities between Sanskrit, the sacred language of the Hindus, and Greek and Latin; but the first statement on the subject which attracted public attention was that made by Sir William Jones, the Chief Justice of Bengal, in addressing the recently founded Asiatic Society of Bengal in the year 1786. In that discussion he pointed out that future investigations would no doubt show that Sanskrit, Greek, Latin, Celtic, and the Teutonic languages were all of one origin, thereby defining, with tolerable exactness, the bounds of the family of languages now known as Indo-European or Indo-Germanic. It was, however, difficult for Europeans to obtain knowledge of Sanskrit. The natives were jealous of Europeans mastering their sacred language, and even when the pundits taught them the classical Sanskrit of the epics, they carefully kept from them knowledge of the earlier forms of language found in the Vedic hymns.* Till this earlier language was known, the similarities between Sanskrit and the languages mentioned of Europe were less conspicuous both in forms and in syntax. The knowledge of Sanskrit was obtained in Europe first from Alexander Hamilton, who had lived for a

long time in India, and who on his return home was captured by Napoleon and kept a prisoner in Paris in the year 1803. There he taught some distinguished scholars, amongst others Friedrich Schlegel and C. Fauriel, who at once realised the importance of the language. Schlegel carried with him the knowledge of Sanskrit to his native Germany, where the study of it soon became popular. He did, however, one serious injury to the study. Schlegel insisted that Sanskrit was the mother tongue from which the other languages mentioned by Sir William Jones were descended, whereas he ought to have regarded it as only the elder sister of these other languages. This mistake proved a serious detriment to the scientific development of the study for at least two generations.

The effect of the discovery of Sanskrit is well elucidated by the writings of Alexander Murray (1776-1813), for a short period in 1812-13 Professor of Oriental Languages in the University of Edinburgh. He had prepared a work comparing the languages of Europe, which, ten years after his untimely death, was published without correction in 1823. But his correspondence with Constable, the publisher, shows that he realised how imperfect his work was, when once he had the opportunity of learning something of Sanskrit. If he had lived his book would no doubt have been the first attempt at a scientific study of the languages which are known as Indo-European or Indo-Germanic. This task ultimately fell to Franz Bopp (1791-1867), who studied in London in 1816 and familiarised himself with the newly discovered language. It was necessary to find a term for the family of languages whose relations had thus been established, and in 1813 Thomas Young, who was both philologist and physicist as well as doctor of medicine by profession, first published, it appears, the word 'Indo-European' in an article in the *Quarterly Review*. It is obvious that he extended the bounds of the family much beyond what is accurate, including amongst other peoples who spoke an Indo-European language, Arabs and Finns.

In 1823 a well-known German philologist, Klaproth, made use of the term 'Indo-Germanic,' but did not claim that it was a new invention, and it is not certainly known whether this was the first use of it. This term has in Britain been used as well as Indo-European. Indo-European has always been used in France but avoided in Germany, where, owing to the pronunciation of the diphthong *eu* as *oi* the word is much more difficult to pronounce than Indo-Germanic. It has been objected that some of the languages, e.g. Armenian and Persian, are neither Indian nor European, and that all European languages do not belong to the family, e.g. Finnish, Hungarian, Turkish, Basque. Indo-Germanic was rather an attempt to define the group by expressing the two ends of the chain, India being the most easterly point and Germany, or rather the lands inhabited by the peoples of Germanic origin, the furthest west. At the time the origin of Celtic was not certainly known. The influence of accent upon this group of languages has changed the form of the words so much that it required very elaborate investigation to discover if they were really of the same stock. But the term Indo-Germanic, even when Celtic was identified as belonging to the same family, was not wrong, because Iceland has been inhabited since 874 A.D. by people speaking a Germanic or Teutonic language, and a language of the same stock has in recent centuries spread over the continent of North America.

In the first stages of the investigation, philologists were content with a general resemblance between words in order to establish, as they thought, a connection between them. But as

investigation continued, it soon became clear that stricter rules were required in order to establish identity of origin between words. Various sound laws were formulated for this purpose. The use of the word 'law' is incorrect because, strictly speaking, a law is issued by some authority, and has attached to it some penalty for its violation. Neither of these features characterises the laws of language. They are, in fact, only observed changes from an earlier state of the language to a later, and clearly if they are to have any scientific value they must be shown to follow definite principles. If in the same circumstances, at the same period and in the same dialect, a sound changed in half-a-dozen different ways, clearly any scientific knowledge would be impossible. On the other hand, the laws of language cannot be compared with the natural laws established for physics or chemistry, because in physics and chemistry, given certain antecedents, the results follow without fail. From two atoms of hydrogen and one of oxygen nothing else can be produced but water, and no such invariable sequence can be postulated for the laws of language. The main reason for the difference is that the action of natural law in the case of sciences such as physics or chemistry cannot in any way be influenced by the human mind; given the antecedents, the result is inevitable. In language, however, the human mind plays a great part in the changes that take place. Through its action, sounds and forms, syntax and meaning all take new and erroneous directions, because the human mind has jumped to the conclusion that things which have some apparent connection are really related when they are not. In English the forms of the noun and the verb have been altered to a very great extent owing to this influence, which at one time was called false analogy and is now generally known by the name analogy without qualification. It is owing to this fallacious play of reason upon the facts of language that the vast majority of substantives in English make their plurals in -s, this suffix being originally only one of several which formed the plural in English. In the same way in the verb the past tense is now in the great majority of verbs made by the suffix -ed. We still preserve in some verbs the old strong conjugation represented by *sing, sang, sung; tear, tore, torn*, and various others, but we have lost all trace of this conjugation in a great number of verbs which once possessed it, though in various dialects traces of the old state of things still survive. Thus the verb *bake* makes its past tense and its past-participle *baked*; but in Scotland the past tense *bek* still survives to this verb, and there are scores of other examples of the same phenomenon.

The first investigators of the Indo-European or Indo-Germanic family of languages contented themselves with discovering the general resemblances between the languages. Bopp, the greatest of them, carried the bounds of the family a good deal beyond what was justified, bringing into it, for example, the languages of the South Sea Islanders, which in some respects have a superficial resemblance, though investigation has shown that they are not really related to the Indo-European family. The first of the etymologists who established relations between the words of the different languages was August F. Pott (1802-87). One of the most striking generalisations made in the early days of the study was that known in Britain as Grimm's Law, but in Germany as the 'sound-shifting.' The main part of this generalisation was discovered by the Dane, Rasmus Kristian Rask (1787-1832), and was elaborated further by the famous German scholar, Jacob Grimm (1785-1863), who published the elaborated form in the

second edition of his German Grammar (*Deutsche Grammatik*) in 1822.

It was observed that many Latin and Greek words had forms akin to them in the Germanic or Teutonic languages, but with a difference in the stopped consonants—*p* being represented by *f*, *b* by *p*, and the original *bh* (surviving as such only in Sanskrit, and represented by *ph* in Greek and by *f* and other sounds in Latin) by *b*. In the same way *t* was represented by the Germanic *th*, *d* by *t*, and *dh* (surviving like *bh* only in Sanskrit while represented in Greek by *th* and in Latin by *f* and other sounds in certain combinations) by *d*. In the same way *k* was represented by *h*, *g* by *k* (*c*), and the original *gh* (surviving only in Sanskrit as before and represented in Greek by *kh* and in Latin by *h* and sometimes other sounds) by *g*. Grimm

This was the 'sound-shifting,' which differentiates modern High German from German of the Platt-Deutsch type, to which English belongs.

There were a number of exceptions to this law which remained for half a century inexplicable. In 1875 the clue to their explanation was discovered in the influence of accent by Karl Verner (1846-96). At this time an attempt was made to formulate the influence of phonetic laws more carefully. This movement began with the works of Professor W. D. Whitney (1827-94), and was propagated by his translator August Leskien (1840-1916), and after him by his friends and former pupils, Karl Brugmann (1849-1919) and Hermann Osthoff (1846-1909). Their views were definitely formulated in the work of Hermann Paul (1846-1921), in his book, published in 1880, *Prinzipien der Sprachgeschichte*, which has gone through five editions. The investigation of dead languages, on which most of the observations (though not Paul's) were founded, led these scholars to regard the working of phonetic laws as a more regular and precise thing than the careful study of living languages has shown it to be; not that the principles are wrong, but that the interchange between dialects is much more extensive than had been supposed.

In 1900 E. Wechssler argued that the changes of sounds were effected in one or other of two ways: (1) there was a gradual and sometimes almost imperceptible change in sounds without external influence in languages remaining on the same area for a long period undisturbed, and (2) the immediate sound change where two languages came in contact as by conquest. In such a case the pronunciation of both parties was likely to change because each would attempt to pronounce the language of the other. It is observed that when grown persons attempt to pronounce foreign languages, as the cartilages of the larynx which have the main work of sound production to carry out are much less movable than in children, they always attempt to produce the effect of the foreign sounds by the nearest sounds in their own language. Thus if they are compelled to adopt a new language, they will have the words of the new language but the sounds will be the nearest sounds they can produce out of their native language. This change is instantaneous and it may be permanent. Thus in most parts of Spanish America the Spaniards were a very small minority in the early days of the Spanish conquest, and as a result kept themselves to themselves, and in this way perpetuated a comparatively pure but ultimately archaic form of Spanish. In Chile, however, they were numerous enough not to be afraid of the natives, and the consequence of greater intermixture is shown by the fact that the native dialect consists of Spanish words, but,

with the sounds not of the 16th century Spanish but of the language of the Araucanian Indians who held the country before the Spanish conquest.

Between 1840 and 1875 the work that was done in Comparative Philology was mainly in the organising of the material already accumulated. The foremost scholar in this direction was August Schleicher (1821-68), whose compendium of comparative grammar was the standard text-book from 1861; the 4th edition appeared after his death in 1876. Another important work of this period was the *Principles of Greek Etymology* of Georg Curtius (1820-85), which appeared first in 1858 (5th ed. 1879). This book, treating of Greek, comprehended a comparison of Greek with Sanskrit, Zend, Latin, Germanic, Letto-Slavonic, and Celtic. It is noticeable in this book what a large number of forms are given which are regarded as being irregular. Another independent thinker of that period was Theodor Benfey (1809-81), and Max Müller's lectures on *The Science of Language* in 1861 and 1864 added very much to the popular interest in the study. The philosophical treatment of language generally was helped greatly by Wilhelm von Humboldt (1767-1835) and his editor, Heymann Steinthal (1823-99). The words that were common to the whole Indo-European family or to its different members were systematically collected by August Fick (1833-1916) in his comparative dictionary of the Indo-Germanic languages (1st ed. 1868, 4th ed., left incomplete, 1890-94). In 1870 the Italian scholar, G. I. Ascoli (1829-1907), showed that the investigation of the sounds of the Indo-European original language was not yet complete, and established that besides *k*, *g*, and *gh*, which are pronounced against the hard palate, there must have been another series produced against the soft palate (velum), and therefore called velar sounds. This last series often had along with them a *w* sound, the combination being represented by the Latin *qu* and the English *wh* which stands for an older *hw*.

In 1876 Karl Brugmann showed that Sanskrit and Greek represented by a vowel alone a sound that in other languages was represented by a vowel and a nasal. Thus Sanskrit *tatás*, Greek *tatós*, Latin *teutus* were the same word made from the same root, and Brugmann was able to show that the explanation of this was that, owing to the stress accent having fallen upon the last syllable, the first syllable was reduced, so that *a* alone made the syllable, all nasals being continuous sounds like vowels, which could be prolonged as long as the breath would hold out. The discoveries of Ascoli, of Verner, and of Brugmann explained a very large number of the forms which had been regarded as irregular, and others were explained by the distinguished mathematician G. Grassmann (1809-77), who in middle life had taken up with great enthusiasm the study of Sanskrit and of Comparative Philology. A law which is generally known by his name as 'Grassmann's Law' showed that in Greek and in Sanskrit aspirated sounds like *dh* or *bh* in Sanskrit, or *th* and *ph* in Greek were avoided in successive syllables, thus removing one of the remaining difficulties about Grimm's Law.

The investigation of all these points was greatly helped by the more accurate representation of the sounds in Sanskrit by its alphabet, the study of Sanskrit having been pursued, from very early times, in India by pundits who were themselves expert phoneticians. The revision of the vowel sounds of these languages began with these discoveries and was systematised first by Ferdinand de Saussure (1857-1913) in his *Mémoire sur le Système Primitif des Voyelles dans les langues indo-européennes* (1879), and the whole of the

sounds of the Indo-European languages were treated with much detail by Brugmann in his *Grundriss*, the first volume of the first edition of which appeared in 1886, the second edition of volume I. in 1897. The second edition is a work of great size and was not entirely complete when the author died in 1919. Besides the sounds, this work treats also of the forms and the syntax of the Indo-European languages.

The investigation of these languages was the first, but it has been succeeded by investigation of the Semitic languages, for which also there is now a comparative grammar by Carl Brockelmann in two volumes, 1908 and 1913. The languages of Africa have also produced grammars of various groups, and the same principles have been found to work equally effectively in all. This is clearly shown by the following remarks of an expert writer upon African languages:

'As we carried our investigations deeper and deeper we were surprised to note how far-reaching and absolute are all the principles and rules. We are able to state and explain them definitely and find them working without exception. Indeed, when an irregularity is found, at once the suspicion is raised that the real principle has not been discovered, and our grammar stands without the usual lists of exceptions. In this respect it figures as an ideal, impossible to our European languages, which have been subject to such interaction and reaction until Celtic, Saxon, and Latin rules have brought about results and changes, so arbitrary and strange as to be almost inexplicable, and we have to state facts as facts and leave them so.'—Benfey, *Dictionary and Grammar of the Kongo Language*, Preface, p. xxi. (1887).

The most effective cause in the complications which this writer notes is analogy, which has already been mentioned. The working of this principle has been carefully examined by B. L. Wheeler in a little treatise entitled *Analogy and the scope of its application in Language* (Ithaca, New York, 1887). Its influence extends throughout the whole field of language to sounds, to forms, to syntax, and to meaning. It is impossible in a short article to enumerate all the forms in which analogy makes its appearance. Its working may be classified under three headings: (1) logical analogy; (2) formal analogy; (3) a combination of 1 and 2. When particular forms of a word influence other forms of the same word we have an example of logical analogy. In the original language from which the various Indo-European languages have descended the paradigm of many nouns showed different forms in the different cases. Thus the word for 'father' was in the nominative *patr*, but its locative case was *pateri*, and its genitive was *patris* or *patris*. The effect of analogy is to reduce this variety so that in Latin we get the shortest form throughout, thus the genitive *patris* and the accusative (which would have been originally *patrem*) *patrem*. It is, however, difficult to say how analogy will work in any particular instance, because in Latin the nouns like *dator*, 'giver', had originally a long *o* in the last syllable, while there was a short vowel in the accusative, and in the middle syllable the vowel altogether disappeared, as in the genitive originally *datus*. These short forms, however, have disappeared and the long *o* has been carried throughout *dātorem*, *dātōris*, &c. And curiously enough through another law of the Latin language whereby a long vowel is shortened after a short vowel, the long vowel of *dātōr* has become short in the classical period, and remains the only short vowel in the paradigm which elsewhere has a long vowel throughout. (In both *pater* and *dator* the *a* of the root syllable in the original paradigm is a reduced

vowel owing to the influence of the strong stress accent falling on the final syllable.)

In formal analogy forms of one word influence forms of another word which does not belong to the same series. Thus the word 'hoe' makes its plural 'hoes,' and as a result of this the word 'hose' has been treated in dialect as a plural making its singular 'ho.' Thus in Allan Ramsay's *Christ's Kirk on the Green* the form *ho*, 'stocking,' occurs as the singular of 'hose.' In a similar way in American dialect *shay* is regarded as the singular of 'chaise.' It is by analogy that the great majority of new words are made, sometimes with curious results. In English we have a form 'worm-eaten,' a properly made compound meaning 'eaten by worms,' but there is a class of workmen who are known as 'worm-eaters.' Their business is not to eat worms but to make holes in furniture to represent the ravages of worms, in order to give the impression of antiquity. In the east end of London some years ago a popular name for a police-man was 'swede-eater,' which was intended to imply that he was a rustic and fed on Swedish turnips. It is through analogy that in Elizabethan English a confusion arose between the verb 'leren' (to teach) and 'learn,' which has led in various dialects to the use of 'learn' in both senses, a use which also can be found in the Prayer-book version of the Psalms and in the Elizabethan writers not infrequently (cf. Ps. xxv. 4, Lead me forth in Thy truth, and *learn* me (Prayer-book); *teach* me (Authorised Version).

A further appearance of irregularity arises from the mixture of dialects. Within a language dialects arise mainly from isolation or bilingualism. Strictly speaking, dialect differences may be seen between members of the same family, but they are much more conspicuous in groups of persons isolated from their nearest neighbours by living, for example, on an island or in a mountain valley. Such isolation tends to greater homogeneity within the small area in constant communication, and greater differentiation from the large area outside, this differentiation arising from new developments within the separate areas. Districts where such dialect differences arise plentifully are in the islands of the Ægean or in the Orkney and Shetland Islands. Bilingualism arises where the speakers of two different languages come to be mixed. The result is a mongrel dialect which is neither language but contains features of both in vocabulary, sounds, morphology, and syntax. A good example of the kind is the Pennsylvania Dutch spoken in America. Less conspicuous but not less common is the mixture in Britain between local dialect and book English. The effect of a language may survive long after the language has ceased to be spoken in the district or even to be understood. Thus in Aberdeenshire, except in the mountainous parts, Gaelic has not been spoken since 1308, when the greater part of the county was ravaged by Robert the Bruce and the Gaelic speakers suppressed and in part at least exterminated. Their places were taken by English speakers who had been established long before in the city of Aberdeen, but to this day Gaelic words survive in the dialect like 'oy' for grandchild, 'caird', 'tinker', 'pluke', 'pimple', &c. In the sounds, the use of *f* in this dialect where English would use *wh* is characteristic of areas where Celtic and Saxon border upon one another. The same change is observed in parts of Ireland, and is given by Elizabethan writers as an Irish characteristic.

It is supposed that the origin of sound-shifting known as 'Grimm's Law' was of the same character. When the two languages are not spoken in the same area, dialect infection may arise from several causes. Geographical proximity is not very

effective because rivers and mountain ranges are both sufficient to reduce the influence very much. Trade is more effective and facility of communication. Political unity attracting the inhabitants to a centre, and conscription, have both much influence in introducing new dialect words. Still more, perhaps, have literature and systematic education. Uniformity over a large area, unless it is free from geographical difficulties, is rarely attainable. The commonest form of infection is by the borrowing of words for implements, wares, and the like. Of these we can see many examples in English. For example, the word 'damsons' includes the name of the city of *Damascus*; 'shalot,' the name of *Askalon*, a city of the Philistines; 'coach,' the name of the town of *Kocs* in Hungary; 'cravat' is a form of the borrowed from the *Cravats*. When [Shakespeare] says: 'You freeze capacities, ye Jane judgments' (*Two Noble Kinsmen*, iii. 5, 9), he is thinking of two fabrics of a rough and inferior character, one named from *Friesland* in the north of Holland, and the other from the city of *Genoa* in Italy, through *Gènes*, the French form of the name.

In all languages there are to a greater or less extent two accents: (1) pitch, which consists in raising or lowering the voice from one note to another, and (2) stress, which consists in emphasising and pronouncing one syllable at the expense of the syllable preceding or succeeding it. Pitch accent has little influence upon modifying the forms of words, but stress accent is very powerful in this respect. If we take a word like the Latin *latrocinium*, there were in this word two stress accents, a subordinate stress accent upon the first syllable and a main stress accent upon the third syllable from the end, it being a rule in Latin that if the second syllable from the end is short the stress is upon the third syllable from the end, and if the second syllable is long, the stress is upon that syllable. The effect of stress accent upon this long word is to cut out the syllable containing *o* and the final syllable, and to reduce the word to the form which we know as *larceny*. The effect of stress accent is to reduce the number of syllables in a word by destroying unaccented short syllables together, and this is the main reason for the great difference in appearance of words in ancient Greek and ancient Latin. The main accent of ancient Greek was pitch, and thus its short syllables remain unimpaired, with the result that it is very easy in Greek to write in dactylic measures (-oo, oo, . . .) owing to the preservation of the short syllables. In Latin and in English, as the short syllables have been very largely destroyed, such metre is very difficult, and in English has never been successful. A great artist like Virgil was able to accomplish it in Latin with success, and its influence was sufficient to perpetuate it till ages came in Roman civilisation, when language reverted to the old trochaic measures (-oo, oo, . . .) which were more suitable to it just as they are to English.

Of the formation of words, very little, as a rule, known for the older period of the languages, like the Indo-European, which have long records, the bulk of the vocabulary being in existence long before the production of any existing documents. At one time Western philologists, following the example of the Indian grammarians of an earlier age, regarded words as consisting of monosyllabic roots to which formative suffixes were added, and the noun, pronoun, and verb were completed by the addition of endings which, in the noun, were supposed to be of the nature (in the majority of cases) of postpositions, expressing local relations, while in the verb there were formative elements for different tense and mood formations, and endings

which represented 1st, 2d, and 3d persons in the singular and plural, with a corresponding set of forms if the language recognised a dual. A dual number was really a luxury, and most of the languages discarded it at an early period. Its use is strictly limited to pairs of things—the two eyes, the two hands, the two horses in the chariot, &c.—but it could not be used for any casual combination of two, like ‘a man and a dog.’ The explanations offered of these formative suffixes and terminations are plausible, but can be no more, because the word is complete before history begins. We can, however, see the same processes going on in later times. In English there was a masculine form *singer*, and a feminine form *songster*. A number of the words ending in *ster* ceased to have a feminine sense, mainly because the work concerned passed from women to men. Thus the word *tapster*, which in Chaucer is feminine, has long ceased to be so, and many of the other words have ceased to live except as proper names—e.g. *Baxter*, which is the feminine of *baker*, and *Webster*, which is the feminine of *weaver*. The result of the feminine value disappearing is that in the case of *songster* a further suffix is added to it belonging to another section of the Indo-European family. The newly-coined word *songstress* contains a second suffix indicating the feminine, which has had a very long history. One of the earliest words to contain it which we know is the Greek *basilissa*, ‘queen.’ Here the ending might arise by analogy from *anassa*, the feminine to *anax*, ‘king.’ In all probability, however, the ending was not Greek, but came into Greek from the population that inhabited Greek lands before the Greeks. But it maintained itself in Greek, and spread from Greek to Latin, particularly after the incoming of Christianity. Thus the feminine of *abbas*, ‘abbot,’ is *abbatissa*, whence *abbess*, and from words of this type the ending has been added by analogy to *songster*.

In many Germanic words there was the ending ‘-ing,’ implying membership of a family or stock, and a large number of place-names in England are derived from such formations. Thus Nottingham (O.E. *Snotung-a-hām*) is the home of the Snotungas, the family of Snot (‘the wise’). The ending was added to one or two words which ended in *l*: thus *æthel*, ‘noble,’ had appended to it the ending *ing*, whence the name of Edgar Ætheling. As not infrequently in language the ending was misunderstood as being *-ling* and not merely *-ing*, and a large number of new words have been made in English with this mistaken ending—nestling, darling, yongling, &c.

Though we cannot trace in the Indo-European languages the development of the verb, it is in all probability a later formation than the substantive. In other languages where the history of the formation is clearer, it seems to be generally true that the verb is of the nature of a participle followed by a personal pronoun, and, as the endings in the Indo-European languages also have a pronominal value, it is very possible, though we cannot trace the process of development, that such is also the origin of the Indo-European verb.

The subject of Comparative Syntax is too long and involved to be treated here, but it may be said in brief that throughout their whole history the Indo-European languages are tending away from synthesis—the making of compound forms such as have been just discussed—towards analysis, the use of separate prepositions with the substantive and auxiliary verbs instead of tense and mood suffixes, and substantives or pronouns as subjects instead of personal endings.

The most recently investigated subject in connection with the development of language is Mean-

ing. How do the meanings of words develop? The subject is complicated, and not yet by any means fully worked out. It is clear that words change their meaning by confusion with some related idea. The relation may be purely accidental, as in the confusion of meaning in English between *pert* and *impertinent*. *Impertinent* is properly a legal word meaning ‘irrelevant’—not bearing on the subject in hand—and it has been established in English since the 14th century at least, its positive form, *pertinent*, being found a century earlier, descended from Norman French and legal Latin. The word *pert* is of the same age, and also of Norman French origin; it represents two Old French and Latin words in its early usages: Latin *apertus*, meaning open, frank, handsome, smart; the other usage representing Latin *expertus*, Old French *asparte* or *esparte*, meaning skilled, ready, clever, and hence ‘saucy’—bordering upon cheeky’ (*Oxford English Dictionary*). This meaning does not properly belong to *impertinent* at all, but it is at this point that the two words get confused, *impertinent* being apparently looked upon as a more dignified and impressive form of *pert*. This confusion was no doubt helped by the existence of *malapert*, which, in spite of its spelling, is not derived from Latin *male* and *apertus*, but from *male* and *expertus*.

In Latin there was an early derivative *captivus* from the root of Latin *capio*, ‘catch.’ The common meaning of the word was ‘prisoner of war,’ or, more generally, a ‘captive.’ The miserable position of such persons in the wars of the Middle Ages led to the further development shown by the form *cutiff*, in Old French *chaitif*, meaning ‘miserable wretch,’ where *miserable* also shows the development from the unhappy condition of a prisoner of war to the mean-spirited character which no doubt was very often connected with it. The word *wretch*, ‘outcast’ or ‘exile,’ has had a similar development of meaning.

When metaphor comes into the meaning it may be difficult to identify the relationship between the words. Thus *cabbage* to the ordinary reader does not suggest the idea of ‘head,’ but the word is really connected with the Latin *caput*. From the same Latin word we get the English word *cattle*, which meant originally ‘property,’ Latin *capitale*, because property in early times consisted mainly of live stock. The same word is disguised in the form *chatel*, now confined in ordinary usage to the plural. The word has been borrowed again by economists in the form of *capital*, which in this sense, according to the *O.E.D.*, is later than 1600. The original notion of ‘head’ survives better in *capital*, ‘the top of a pillar.’ The difference of pronunciation between ‘cattle’ and ‘chatel’ depends upon the French dialects from which the two were drawn. The word *case*, ‘an event,’ and the similarly spelt *case*, ‘receptacle,’ come from two distinct Latin words, the first from the Latin *casus*, the second from the Latin *capsa*, ‘box.’ From the second word also comes *cash*, arising naturally from the connected ideas of the container and the thing contained; but much further removed is the word *sash*, the meaning and pronunciation of which are affected by the Old French *chasse*.

It is curious to observe how the metaphor attached to particular kinds of seats has established itself for many different offices and professions. Thus we find the throne, the bishop’s see, the judge’s bench, the professor’s chair, the prebend’s stall, and the orator’s stump. In Ashanti, the golden stool was an extremely important symbol. So the Persian divan was first a sofa, and then a tribunal, and in barons’ halls and English colleges, the dais, where the distinguished members of the household or the visitors sat, was first the table itself, Latin *discus* (borrowed from Greek), and

afterwards 'canopy' over a seat of state or the seat itself. Some words which have come by metonymy have ousted the words which they represented: thus the 'bar' has come to be the generic word for 'advocates in court' in English, Barristers, because historically they were called to the bar, the division between the benchers and the students of law whom they were invited to take a prominent part in legal discussions (*O.E.D.*). Similar developments are the bench for the body of judges, the Front Bench for Cabinet Members of Parliament, the word *Cabinet* itself, in its political signification, the Treasury, the War Office, the Board of Green Cloth. Sometimes the meaning of the word or part of the word might be entirely obscured, and we can use a combination which is a contradiction in terms. Thus in English we can talk of *brass fire-irons* and in French of a *bonnet de coton de soie* 'cotton bonnet of silk,' the first part of the combination having come to represent a particular shape without regard to the material. A more remarkable application of a word is in *tirk* as the cover of bedding, which came to us from the Latin *theca*, 'receptacle' or 'case,' which itself was borrowed from the Greek *thēkē*.

With a change of meaning a word may long survive when its original value is forgotten and a new word for that value has had to be coined or borrowed. Thus the Latin *culina* has been specialised in English in the sense of 'kitchen,' and the Latin word *coquina* of the same origin but not found in classical authors at all, but frequently in other sources, has taken its place in the English word 'kitchen' (Anglo-Saxon *cyecne*, from the late Latin form *cucina*). Sometimes words arose by mistake. Hence all ghost words, of which examples may be found in English in *gravy*, which ought to be *gravy*, as a soup with grains in it; or *celt*, a stone axe, or *terragant*, which ought to be *terragant*. It is suggested that *taper*, a wax candle, has developed out of the Latin *peppyrus*, the meaning having passed from the wick to the candle made round it. The word *jackanapes*, applied to a monkey, meant originally 'Jack of Naples,' and occurs first as a 'nickname of William de la Pole, Duke of Suffolk, murdered in 1450, whose badge was a dog and chain such as was usually attached to a tame ape' (Skeat). But it is possible that this usage first started by a transference of the name from the master of the monkey to the monkey.

In all this investigation it has carefully to be borne in mind that the speaking of a particular language is not necessarily connected with race in any way. There are at the present day, besides people of English birth and breeding who talk English, many other races, negroes, Chinamen, Maoris, and others who speak English as acquired by themselves or their forefathers from English speakers. Throughout the whole history of the study there have been continual mistakes made through confusion between language and race, a confusion increased by the use of the same word for the language and for the people who speak it. The language, for example, may be Indo-European, but in the earlier stages of those languages it is safer not to commit ourselves as to the racial character of the speakers, and if we use the word *Viros* for the speakers (Latin *vir*, Sanskrit *viras*, Lithuanian *vyras*, 'man'), we are able to distinguish between the speakers, whatever they may be, and the origin of the language. It is often very difficult or impossible to tell where a language was first spoken: the peoples of the earth are continually in movement; sometimes it has happened that a whole people has left its original habitat and moved elsewhere, and at all times there have been accretions to the population by commerce, by conquest, or by the incorporation into the com-

munity of slaves thus acquired. Changes of method in farming, coupled with other economic changes, may lead to entire change in the population of a district. Thus we know that in Italy at the end of the second Punic war the country was left entirely ruined by Hannibal. The great bulk of the able-bodied male population had been embodied in Roman armies, and those who were not killed in the course of the war found themselves without capital to restore their farms, and no doubt in many cases without inclination to resume an agricultural life. The result was that the wealthy citizens of Rome acquired large areas of land in Italy which were no longer worked by free men with very few slaves, but tilled mainly by slaves working in great gangs, herded together in workhouses (*ergastula*), and when employed in the fields loaded with chains to prevent their escape. There can be no doubt that in Southern Italy there is a large amount of alien blood imported into the country during this period, when farming on a great scale (*latifundia*) prevailed.

Small communities have frequently migrated, but it is not very often that we can trace migration of tribes of great size from one place to another far distant. One of the most famous migrations of this kind is that of the Kalnucks from the Volga into China in 1771 A.D., a migration which caused them a great deal of loss in lives, but which was ultimately effective. Most migrations begin with pioneers who, driven by need of greater supplies of food for themselves and for their flocks and herds, sally forth in hope that they may find a better country. Other causes may be disease (plague and the like) or great floods. It has been suggested that floods were the origin of the great movement of the Cimbric and Teutonic in the 1st century B.C. from Northern Europe into Gaul. If the country is thinly peopled, it is possible for the newcomers to settle in small numbers without disturbance, or if there is hostility at the outset it presently passes over. Thus in Asia Minor, till after 1920, villages existed within a few miles of one another inhabited by different populations, Turk, Armenian, Greek, with here and there also a little colony of Circassians. The contact of peoples like these, speaking very different languages, leads in time to alteration in speech. In some parts of Asia Minor before the war of 1914-18 the Greek population was gradually losing its language under the pressure of Turkish. The population was poor, and the women had to go out as servants to Turkish mistresses. They had thus to become bilingual, and, as Turkish was the language of the ruling authority, Greek was steadily giving way more and more to Turkish. When the women learnt a foreign language, as in this case, the children also naturally learn it more easily than if the men alone learn a foreign language. The same thing has been observed nearer home. About 1890, in some villages on the east coast of Ross-shire, the establishment of School Board education, with the teaching at that time entirely in English, had led to a break of communication even within families, the grandparents speaking Gaelic only, the parents speaking both English and Gaelic, and the children English only, so that grandparents and grandchildren had no means of language communication in the absence of the parents.

It is impossible to say how many languages have perished from Europe altogether. Basque is reputed to be the remains, surviving in a small area in the Pyrenees, of a language which at one time extended over a great part of Western Europe, including the British Isles. Etruscan, which was the language of a powerful people who disputed for centuries the dominion of Italy with the Romans

prior to the 5th century B.C., as a living tongue entirely disappeared many centuries ago. Mes-sapian, the language spoken in the heel of Italy, is represented only by a few inscriptions from times preceding the Christian era. The original speakers of Welsh and Irish and Gaelic (which is only a dialect of Irish) were invaders of the British Isles. Other invaders of the same area, whose language has entirely disappeared, were the Norsemen and Norman French. But though these languages have disappeared there are traces of them still remaining. Norman French exercised a very great influence upon the history of the language, ingrafting into it many new words and helping to modify its inflections which were already decadent before Norman French came in. Some elements in the vocabulary like *egg* for the Middle English *ei*, the pronoun *them*, and the verb form *are* show survivals from the language of the invading Norsemen.

It remains to classify briefly the languages of the world.

I. *Indo-European Languages*.—These, because of the energy of their speakers, have become the most important in the world, as being the languages of the most important ruling and commercial nations. The languages extend from India to Iceland.

(1) *The Aryan group*.—This name, which has been sometimes wrongly applied to the whole Indo-European family of languages, properly belongs only to the languages spoken in ancient times in Persia and in Northern India. The oldest language of India belonging to this type is Sanskrit, which, without doubt, was brought into India by invaders at some period before 1000 B.C. Closely related to it are the ancient languages of Persia, which are known to us from the Avesta (East Persian), the inscriptions of Darius the Great and his successors from 520 to 323 B.C. (Western Persian), the remains of Sogdian (North-eastern Persian), which have been recently discovered, and records found in recent years in Khotan, the language of which is considered to represent that of the ancient Saccæ. There are many sound changes which disguise the relationship between the Avesta and the old Persian inscriptions on the one side, and Sanskrit on the other, but the vocabulary is to a large extent the same, and it is sometimes possible to transliterate whole sentences from Sanskrit to Persian, or *vice versa*. The date of the Avesta is uncertain, the great prophet of Iran, its reputed author, being dated variously between 1000 B.C. and 600 B.C. From Sanskrit, with greater or less admixture of other elements, come the modern languages of this stock in Northern India, like Hindi and Bengali and many others; to an intermediate stage belongs Pāli, the sacred language of Buddhism, with sound changes from Sanskrit, which are curiously parallel to those between Vulgar Latin and Italian.

(2) Further to the west comes *Armenian*, which is known to us only from Christian times. The language has undergone a serious change, so that the sounds *b*, *d*, and *g* have changed like those sounds in the Germanic languages to *p*, *t*, and *k*, although the Armenians continued to write them with the old symbols much as if we were still to write in English *pater* and pronounce it *father*.

(3) Next to Armenian come the *Slavonic* languages, which occupy a vast area in Eastern Europe and in Northern Asia. The oldest Slavonic literature is in a lost dialect known as Old Ecclesiastical Slavonic, which was probably the language of Bulgaria before the invasion of the Mongols seriously altered the language, reducing its seven cases to two, and making many other changes. In Russian there are three dialects or sub-languages: (a) Great Russian, the centre of

which is Moscow, has become the literary language; (b) the language of the Ukraine is Little Russian; and (c) the language of Western Russia is White Russian. Closely related are the languages of Serbia and Croatia, the dialectic differences between which have been produced largely through religious separation, the Serbs belonging to the Greek Church and the Croats to the Roman Church. To the north of these are spoken the languages of Czecho-Slovakia. Bohemian, with a great literature, and the language of the Slovaks to the south-east in the Moravian area and part of what was Hungary. West of Russia comes Polish, also with a great literature. The Baltic languages, Lithuanian, Lettish and Old Prussian (extinct since the 17th century), probably separated early from the Slavonic stock, and preserve some very archaic features. For centuries subject to Germans and Russians the Lithuanians and Letts, as one of the results of the war of 1914-1919, have become independent, so that their languages have now a better chance of survival.

(4) With these languages spoken over great areas, may come one of very limited territory—*Albanian*, spoken in the mountains on the east side of the Adriatic and overflowing into Greece.

All the languages mentioned have one characteristic which separates them from those to follow, in that they convert original guttural sounds, *k*, *g*, *gh* into some sort of a sibilant, represented in Sanskrit by *ç*, *j*, and *jh* (*h*), and in Russian by *s* and *z*, the aspirated guttural *gh* being confused with *g*, and both being represented by the same sound *z*.

(5) West of all of these, except Albanian, comes ancient *Greek*, which was spoken over roughly the same area as modern Greek till modern Greek was, in 1922, ousted from Asia Minor. Owing to the mountainous character of the country it was divided into a great number of dialects, which are generally classified under three heads: (i.) *Æolic*, spoken in the North of Greece and in North-West Asia Minor; (ii.) *Attic-Ionic*, spoken in Attica (but in prehistoric times also in parts of the Peloponnese), in some of the islands of the *Ægean* and on the central part of the coast of Asia Minor, Ephesus and Miletus being two of its greatest cities; (iii.) *Doric*, which came into Greece later than the other dialects and with great differences in detail, extended from Epirus to the south of the Peloponnese, to the islands of Thera and Melos, to Crete, to Rhodes, to the adjacent islands and coasts of Asia Minor, and west and south in Sicily and Cyrene. The oldest form of Greek is found in the central Peloponnese, in Arcadia, which the Dorians were never able to conquer owing to its mountainous character. Closely akin to this dialect is the far-distant dialect of the island of Cyprus, which must have been colonised at a time when the speakers of Arcadian still lived upon the seacoast.

(6) *The Languages of Italy*.—In ancient times Latin occupied only a very small part of Italy on the south side of the river Tiber, although by conquest at later times it gradually extended its power first over Italy and then over the countries bordering on the Mediterranean, and still later to northern countries like Gaul and Britain, and to the far east till it reached Mesopotamia. The languages of Italy which are akin to Latin, and of which considerable remains survive, are Umbrian, Oscan, and Pæligian. These languages differ in many respects from Latin, but the most characteristic feature is the use of *p* and *b* where Latin has *qu* and *v*. Thus, corresponding to the Latin *quis*, 'who,' they have *pis*, and equivalent in meaning to the Latin *venerit*, 'he shall have come,' is the Oscan *venust*. There were many other dialects, whose speakers figure in history like Sabine and Volscian, but of them we know very little. In Italy, besides these lan-

guages which are of the same stock, there was Messapian, already mentioned, in the heel of Italy, and Venetic, which was spoken by a tribe extending from the Po to Venice. On the western side, north of the Tiber, were the Etruscans, whose language was entirely different, the speakers of which were most probably migrants from the coast of Asia Minor. On the Gulf of Genoa there were the Ligurians, whose language has disappeared. When the Romans had conquered most of western Europe, Latin was adopted as the language of government and trade. The sounds of this adopted Latin varied according to the languages previously spoken in the different areas. It also varied to some extent according to the time when Latin was introduced, Latin itself having changed greatly in the period between 235 B.C., when it was introduced into Sardinia, and the early 2d century A.D. when Trajan established soldier-colonies, from which it is believed Rumanian is descended. Spanish began before 200 B.C., Provençal about 100 B.C., French with the conquests of Julius Caesar, 58-49 B.C., Rumanian with the conquests of Tiberius in the Alps, 15 B.C. Italian is the continuation of the old Vulgar Latin. Naturally, all the languages springing from Latin have modifications, produced by borrowing and by mixture with other peoples.

(7) The ancient area corresponding roughly to modern France was named Gallia, and was occupied by people speaking a Celtic tongue. From Gaul and what is now Belgium no doubt migrated the Celts, who occupied under the name of Britons the greater part of Britain before the invasion of the Romans and the later conquest by the Saxons. The dialect which is still represented by Welsh, and which has left some remains also in Cornwall, and in a slightly different form in Brittany, is differentiated from the kindred language spoken in Ireland and in the Scottish Highlands and the Isle of Man by the same differences that we saw in Italy between Latin and the other dialects. In Welsh and its cognates *p* appears where the other dialects have a representation of *qu*: thus the word corresponding to the Latin *quattuor*, 'four,' appeared in Gaulish as *petora*, in Welsh as *pedwar*, in Irish as *ceithir*.

(8) To the north-east of Gaul lay the country of the German-speaking peoples, whose languages fall into three groups: (a) Gothic, spoken in the 4th century A.D. on the Danube; (b) Norse, one language to about 1000 A.D., and then splitting up into Danish, Swedish, Norwegian, and Icelandic; (c) Western Germanic, including the language of Germany proper, the literary language representing High German, while the language of Northern Germany, Low German, is represented only by Platt-Deutsch. Closely related to it are the languages of Holland and Belgium (Flemish) and English, though modern English has had a huge influx of words from Norman French, and at an earlier period a smaller influx of words from Norse.

Besides these eight groups, in recent times Indo-European speakers have appeared in very early records (about 1300 B.C.), discovered in 1906 by the Germans at Boghaz-Keni in eastern Asia Minor, on the site of the ancient Pteria. One of eight languages found in those tablets curiously enough bears a very close resemblance to Latin, making its passive as Latin does by an *r* suffix, a peculiarity known before only in Italic and Celtic languages. The further relations of this language have still to be investigated.

In recent years also a new Indo-European language has appeared in Chinese Turkestan, in two dialects, one of which was apparently literary and the other used for colloquial and business purposes. This also makes its passive in the same way as

Italian and Celtic. It has, too, some curious points of resemblance to the newly-discovered language in Asia Minor, which has been called provisionally 'Kanisian' instead of Hittite, as it was at first wrongly designated, while that in Chinese Turkestan has been named 'Tocharish,' from an ancient tribe which is supposed to have lived in those parts.

II. Next in intellectual importance to the human race is the group of languages known since the 18th century as the Semitic. (1) The earliest known of its branches is that which was settled in lower Mesopotamia at least 3000 years B.C. First from Babylon, and at a later time from Nineveh the capital of Assyria, this branch of the stock exercised great political and intellectual influence. Its cuneiform script, adopted from the older Sumerian settlers in the same area, of whom little as yet is known, was learnt and used by other races in Asia Minor. (2) From a very early time the civilisation of Babylon was in touch with that of Egypt. The ancient Egyptian language was apparently a branch of the same stock, which had been early separated from the other branches and had a large foreign element incorporated in it. (3) (a) As early as the 14th century B.C. records exist of another branch which had established itself in Palestine and was in communication with Ikhmaton, the heretic king of Egypt, at Tell el Amarna. (b) In a dialect of this branch was written in the early part of the 6th century B.C. the famous inscription of Meshah, king of Moab, the fragments of which are now reserved in the Louvre. (c) But far the most important of its dialects is the Hebrew in which the Old Testament is written, some part of it reaching back to at least 1000 B.C. (d) Closely kin was Phœnician, the language of the great commercial cities Tyre and Sidon. These towns had trading centres established round all the shores of the Mediterranean; the most famous was Carthage. More of the early inscriptions of this dialect, reaching back to the 9th or 10th century B.C., are found in Cyprus than in Phœnicia itself. (4) From 1400 B.C. we hear of the Aramaeans as a nomad robber stock of the desert in the west of Mesopotamia. They ultimately settled eastward of Palestine in Syria, and became the great commercial people of Western Asia. In Turkestan many documents have been found written in a dialect of northern India, but docketed by a Syrian clerk in his own language, Aramaic. This language was finally crushed by (5) Arabic, which from the time of Mohammed spread far and wide. Though as early known, this language has preserved better than others many of the most primitive features of the Semitic. In modern times there are wide differences between Arabic as spoken in Arabia and in Egypt, Mesopotamia, Syria, and North-west Africa. (6) In the south of Arabia a dialect was developed, the inscriptions of which are written in a fine bold phœnician of the same origin as the Phœnician. (7) An offshoot from this dialect is the language strongly mixed with other elements which was established by emigrants to Abyssinia, and of which Geez and Amharic represent the languages which in old and modern days were spoken at the King's Court. More distantly related are the Berber dialects and the extinct Guanche, the language of the Canary Islands. Still more remote are the languages of Cush, the Somali, Galla, and other tongues spoken between the Nile south of Egypt and the Red Sea and Indian Ocean.

III. A large group in close touch with the Indo-European languages from the beginning of our records is the Finno-Ugric. Its home was probably the central Urals. It divided into two sections, the Ugric consisting of Hungarian, which established itself in the ancient Pannonia, Vogul about

Perm and Tobolsk, and Ostyak on the river Obi and its tributaries. The Syriian is spoken by a large population in the districts of Perm, Viatka, Archangel, and Vologda, who are active agriculturists and traders. Still more numerous are the Viatiks in Viatka and Ufa, next to whom are the Cheremissians. On the middle Volga the Mordvinian language is widely spoken. The other section consists of Finnish spoken in Finland by the bulk of the population, and by some settlers in Sweden and Norway. Finnish has a literature from the middle of the 16th century. Estonian is spoken in Estonia and Livonia, and there are other dialects of less importance. The Lapps are not of the same racial stock, but speak a language akin to Finnish. The language of the Samoyedes is akin, and all the languages mentioned are included by some scholars in an Ural-Altai group, which would also comprise the Turko-Tataric languages, the Mongolian, Manchu, Tungus, and possibly the Japanese and the Korean. With this group the Dravidian languages of India, Tamil, Telugu, Canarese, and in Baluchistan Brahui, are said to have many similarities.

IV. The languages of the Caucasus are numerous, many of them confined to small mountain valleys and but little known. They fall into two groups with an elaborate consonant system. Some show many combinations of consonants difficult for a European to pronounce. The most important on the south side are the Georgian and the Mingrelian, on the north side the Circassian and the Lezghian, the former now much reduced by the migration of most of its Mohammedan speakers from Russian territory into Turkish Asia Minor. Possibly connected with the Caucasian group was the language of the ancient Hittites resident in Asia Minor eastwards of the river Halys; Lydian and Etruscan were probably also related. Some see in Basque, spoken on both sides of the western Pyrenees, a language isolated from this group, but this is still very uncertain.

V. In Eastern Asia very different from all the foregoing languages is Chinese spoken by some four hundred million persons. It has no grammar in the European sense, and no inflection of any kind, so that the sense has to depend on the order of the words in the sentence. Its writing is developed out of picture-writing, and is intelligible all over China, though speakers in distant parts may not understand each other. Once Chinese was regarded as the type of the most primitive language with no noun cases and no parts of the verb. Now, however, Chinese is considered to have gone through something of the same changes as English, which has nearly discarded its inflections also. Other languages like Chinese but with some attempt at compound forms, as when a lantern is called a 'light cage,' are Burmese and Siamese. Another branch of this family is represented by Tibetan, where the forms are not so broken down as in the other languages.

VI. For the group called Munda, or Mon-Khmer, extending sporadically from the plateau of Chota Nagpur to Annam, see vol. iii. part i. and vol. iv. of *The Linguistic Survey of India*, edited by Sir G. A. Grierson, a work in which much valuable material regarding all Indian languages is collected.

VII. The Malayo-Polynesian languages are found from Madagascar to Easter Island, and include a vast variety of tongues which are classified as Indonesian (spoken in the Philippines, Celebes, Madagascar, Sumatra, Java), Melanesian (in Fiji and a great number of other islands), Micronesian (spoken in the Gilbert, Marshall, Caroline and Marianne groups, and Yap island), and Polynesian (including the languages of Samoa, the Society Islands, Tonga, Easter Island, and the Maori of New Zealand).

VIII. The Papuan of New Guinea and adjacent small islands.

IX. The native tongues of Australia, in which some see relations of the Mon-Khmer languages of India.

X. The languages of the Sudan and of Guinea. Of these the most important is Hausa, the language of the negroes of northern tropical Africa.

XI. The Bantu family of languages extending from Southern Nigeria to the Cape of Good Hope. Sir Harry Johnston finds that there are 366 Bantu languages and other 87 closely akin. Of many of these only lists of words are known.

XII. The languages of the Bushmen and Hottentots. The Bushmen appear to be the last remains of a Palaeolithic age. They have gradually been driven southwards by the Bantu-speaking peoples, and will soon be extinct.

XIII. The native languages of America. Of many of these little is yet known. They are often described as 'incorporating' languages, because subject, object, predication, and qualifying circumstances may be all joined together in one huge word. It is now, however, certain that there are considerable variations in the type. None of the languages were the vehicle of a high civilisation but the Nahuatl of Mexico, the Maya of Central America, and the Quichua of Peru. These languages are classified geographically as Arctic (languages of Greenland, &c.), North American, Central American, and South American.

Philomela, according to the Greek legend, was changed into either a swallow or a nightingale. Poets are (or rather were) fond of calling the nightingale by its classic name.

Philopomen, a patriot of Greece, was born at Megalopolis about 252 B.C. In 232 he was one of the defenders of Megalopolis against Cleomenes, king of Sparta, and next year he fought with the Macedonians against the Spartans. He then served in Crete with such distinction that in 210 he was appointed general of the Achaean horse. In 208 he was raised to the highest military dignity in Greece, being elected *stratigos* or commander-in-chief of the Achaean League. The battle of Mantinea (208), in which the Spartans were again utterly routed, raised him to the pinnacle of fame, and at the Nemean festival which followed he was proclaimed liberator of Greece. So great was his influence that the Macedonian monarch, Philip V., began to fear that Greece would regain its independence, and tried, vainly, to have him secretly assassinated. During the next few years he was absent in Crete, and returned to the Peloponnese in 194 to find the Romans in Greece. On the departure of the consul Flamininus, Nabis of Sparta recommenced hostilities against the

Achæans; Philopœmen was once more appointed strategos (192), and in a pitched battle nearly annihilated the troops of Nabis. He now exerted all his power to heal the divisions among the Achæans, and to prevent them from affording the Romans a pretext for taking away their independence. In 188 he took a fierce revenge on Sparta for having put a number of his friends to death, and was in consequence strenuously censured by the Roman senate, and by Q. Cæcilius Metellus, who was sent out as a commissioner to Greece in 185. Two years later Philopœmen (now an old man of seventy) was elected strategos for the eighth time. When lying ill of a fever at Argos he rose from his sick-bed to quell the revolt of the Messenians, but was overpowered by numbers, and fell into the hands of Democrates, the leader of the Messenians, who two nights after sent him a cup of poison. Philopœmen drank it and died.

Philosopher's Stone. See ALCHEMY.

Philosophy. In a subject where opinion has been and is still so much divided, as is the case in philosophy, the historical method is our only safe guide in arriving at a definition. 'The objects of the inquiry, its methods, nay, its very possibility, are still matter of debate between divergent schools. But by a review of the history of the term and the more important changes in usage, it is possible to reach a fairly accurate idea of what philosophy has meant in the past.'

Tradition assigns the first employment of the word to Pythagoras, and makes him use it to signify merely the disinterested pursuit of knowledge. Socrates plays upon the etymology of the word when he contrasts the modesty of the truth-seeker with the more arrogant pretensions of the Sophists. But, so far, the nature of the truth or knowledge which the philosopher seeks is not specified; the term is still vague and general. Aristotle still uses the term to cover the whole field of scientific activity as well as those more strictly philosophical investigations to which he gives the name of 'First Philosophy,' or, as a modern might say, first principles of knowing and being. In fact, no kind of knowledge was at first alien to the philosopher. Philosophy has been truly called 'the mother of the sciences,' and it was only by slow degrees that the separate sciences attained an independent life. As specialisation proceeded, however, philosophy could no longer in a *literal sense* 'take all knowledge to be her province'; the details of one department after another of existence were surrendered to the scientific specialist. But the claim of philosophy to be the necessary complement of the special sciences—the only science of existence or of the universe as a whole—was not thereby surrendered. The specialist, so far as he is a mere specialist, is like the man who cannot see the wood for the trees; he loses sight of the proportions of the whole in the details of his own province. The co-ordination of the sciences, the unification of knowledge, is a task which remains to be undertaken by the philosopher. Unity or harmony in our conception of the universe is the aim which philosophy always has in view. Whether this aim is attainable by man or not is a further question; but the idea of a system of things satisfactory to the reason and the moral sense remains the inexhaustible spring of philosophic effort. The philosopher, therefore, has always his eye upon the Whole; his true function is to correct the abstractions of the special sciences. Each science makes, and must make, its own working postulates or presuppositions, and the specialist is ever prone to make the working postulates of his own department the measuring-line of existence as such. But philosophy has to review

all these scientific postulates, and if possible to harmonise their conflicting claims by showing the relative and limited validity which belongs to each. Philosophy is in this connection the critic of the sciences—of the postulates which they make and the conceptions which they use; and she exercises this critical office in the interest of the Whole. Something like this was present to Plato's mind when he described the philosopher as *synoptikos*, a man who insists on seeing things together, who refuses to consider the parts out of their relation to the whole whose parts they are, and who is therefore the inexorable foe of crude and premature generalisations from this or the other department of investigation which happens for the time to be most in evidence.

The insistent demand of reason for unity or harmony is possibly better expressed as the demand for a system in which room may be found for all the elements or aspects of human experience, aspects sometimes at first sight contradictory. In modern times, and especially during the 19th century, the advance of physical science seemed to many to disclose such a contradiction between the strict mechanical determinism of the universe as physically conceived and the postulates of the ethical and religious consciousness; and the problem of philosophy assumed the special form of an attempt to mediate between these claims. So it is formulated by Lotze in his *Microcosmus* (1856), and Spencer's doctrine of the Unknowable was put in the forefront of his *First Principles* (1862) expressly as the reconciliation of religion and science. Similarly Sidgwick, at the close of the century, lays down as 'the final and most important task of philosophy the problem of connecting fact and ideal in some rational and satisfactory manner' (*Philosophy, its Scope and Relations*, 1902). The conception of 'worth' or 'value' has been very prominent in recent discussion, which has centred in the question of the relation of human values or ideals to the ultimate ground of the universe. Philosophy thus becomes, as it has been phrased, the struggle for a *Weltanschauung*, the effort, that is to say, to reach a coherent and ultimately satisfactory view of the world, satisfactory not in the sense of gratifying all our wishes, but as not doing despite to that which we recognise as best and greatest in ourselves. In the course of this conflict there emerges the sharp opposition of idealism and materialism or naturalism.

From the time of Socrates at least, but more especially in modern times, philosophy has also been occupied by the question of the nature and limits of knowledge and the criteria of certainty. Such critical reflections are the natural sequel of a difficult and dubious inquiry such as philosophy undertakes into the ultimate nature of things. Attempts at a theory of being (ontology or metaphysics) lead naturally to a review of the competence of the human mind for such an undertaking, and to a theory of knowledge generally (epistemology, *Erkenntnistheorie*). In the hands of the Sophists, who were the first to deal with this side of the philosophical problem, the inquiry led to a sceptical or purely subjectivist doctrine of the relativity of truth. In their doctrine of concepts or general notions, ascertainable by definition, Socrates and Plato sought to vindicate the possibility of a common or objective knowledge which would put us in touch with the reality of things. In this connection Plato defines the philosopher as the man who apprehends and follows after the essence or reality of things as opposed to the man who dwells in appearances and the shows of sense. Such a distinction between the phenomenon, the world as it first *appears* to sense and unreflective thought, and the *noumenon*, the world, as reason

ultimately recognises it to *be*, may be said to be implied in the demand for any explanation at all, and had, indeed, been explicitly formulated before Plato in the systems (otherwise diametrically opposed) of Heraclitus and Parmenides. But the formulation of it by Plato in his doctrine of Ideas led (probably through a misunderstanding of his real meaning) to a separation of the world of noumenal reality from the world of actual experience, which converts the former into a metempirical or transcendent entity completely inaccessible to human reason. Such may be said to be the sense attached to the distinction between phenomena and noumena in popular thought, and to it we owe the Positivism of Comte and the Kantian and other forms of Phenomenalism, which limit our knowledge to phenomena and their laws, and deny the possibility of the metaphysical inquiry. To Comte, metaphysics, or philosophy in the older sense of the term, appears as a disease of the human mind, from which, under the influence of science, it is happily recovering. For Kant, intellectual philosophy becomes a 'criticism' of the forms and categories of human thought, in order to fix the bounds of possible knowledge and of necessary ignorance. The same result is reached in the empirical scepticism of Hume, to whom philosophy appears as a preventive against itself, or at least against what has ordinarily been understood by the name. In his own words, 'we must submit to this fatigue, in order to live at ease ever after; and must cultivate true metaphysics with some care in order to destroy the false and adulterate.'

Positivism or phenomenalism, however, is chiefly the result of an unwarrantable separation of essence and appearance, of noumena and phenomena. If the noumenal reality is something transcendent, something apart from the world we know, and as it were hidden behind it, then it must inevitably drift into the position of an otiose and unknown thing-in-itself, which has no function to discharge in the universe of knowledge. Whether we then continue to assert its existence, as an Unknown and Unknowable, or take up a purely sceptical position in regard to it, is really of little moment. In both cases the limitation of knowledge to phenomena is justified only by the false definition of the essence or noumenon from which the theories in question start. But the noumenon is not truly conceived as a transcendent entity apart from the phenomenon: it is simply the phenomenon itself fully understood. To know only phenomena would be to rest content with the immediate appearances of sense. All science is an attempt to go beyond the immediate appearance, and to understand it by connecting it with something else. Ultimately no one thing can be fully understood except in the light of the whole; so to understand things is to see them as they really are, and to know the ultimate truth about the universe. The object of the philosopher is not to reach a second and more recondite *kind* of reality, but to give an ultimately coherent account of the reality we know. Following out this line of thought, the modern philosopher often gives his question a teleological than an ontological form. Instead of asking what is the ultimate essence, he asks what is the ultimate meaning, significance, or end of the universe. Has it a rational and satisfying end? Does it exist to express a meaning at all, or simply as a brute fact? But end, meaning, and ultimate reality are only different ways of formulating the same problem.

Apart from this general question just discussed, the theory of knowledge has been much concerned in modern philosophy with the issue between realism and subjective idealism, that is to say, with the question how the individual knower comes to know anything beyond his own mental

states. But this supposed difficulty may likewise be traced to an initial error in the statement of the problem. The question at issue between transcendentalism and empiricism, as to the presence of *a priori* necessities or categories and forms of reason in the constitution of experience, may be said to form a part of the theory of knowledge, as well as such general questions as the nature of certainty, the distinction between knowledge and belief, and the grounds of belief and disbelief. Theory of knowledge here passes into logic, and the two names are sometimes used interchangeably.

The term Philosophy, although generally identified with the two central inquiries described in the foregoing paragraphs—Metaphysics and Theory of Knowledge—has in common usage a wider application. Besides these central disciplines it embraces what may be called the philosophical sciences, such as Logic, Ethics, Aesthetics, Psychology, Sociology, the Philosophy of Law, the Philosophy of Religion, and the Philosophy of History. Some of these, however, have two sides, and may be treated either as positive sciences or as parts of philosophy. Psychology, by which is understood what was formerly called Empirical Psychology, may be said to have established its claim to be an independent science of observation and experiment. But although its standpoint, so conceived, is different, its connection with philosophy must remain, seeing that the knowing mind is the object which the psychologist investigates. Similarly, Ethics is often treated as the natural history of moral ideas and institutions or of the moral sense, but so conceived it really forms a part of scientific psychology and sociology. The strictly philosophical part of Ethics is the theory of obligation, and this is sometimes spoken of as the Metaphysic of Ethics. The meaning assigned to duty and the explanation given of it must of necessity profoundly influence the general conception we may form of the universe. So, again, Aesthetics may be treated as a department of physiological psychology, as has mostly been the case in England; but by many continental writers the Philosophy of Art or the Philosophy of the Beautiful has been intimately connected with metaphysics. Jurisprudence on its philosophical side is closely connected with Ethics, and is sometimes spoken of as the Philosophy of Law. The Philosophy of History and the Philosophy of Religion exist only so far as there can be traced in the facts of history and in the different religions of man the evolution of an idea or purpose. Logic, as an analysis of the nature of inference or the general theory of proof, occupies a propaedeutic or introductory position in relation to philosophy, and indeed in relation to scientific thought generally.

The History of Philosophy forms not the least important philosophical discipline. Philosophy cannot, indeed, be profitably studied apart from the history of its own development. Speculative thought has flourished in India and elsewhere, but the history of European philosophy begins with Thales in Greece about 600 B.C. It is usual to distinguish three great periods of philosophic thought—Ancient or Greek Philosophy, from 600 B.C. to about 500 A.D.; Medieval Philosophy, lasting till 1600; and Modern Philosophy, since that date. Greek Philosophy is in turn divided into three periods—that of the pre-Socratic philosophers (say 600 to 425 B.C.), who devoted their attention mainly to the phenomena of external nature. Pythagoras, Parmenides, Heraclitus, Empedocles, Democritus, and Anaxagoras were the most eminent heads of mutually conflicting schools. The Sophists and Socrates raised the question of knowledge, turning man's attention upon himself; and in the idealistic systems of Plato and Aristotle

(say 400-322 B.C.) we have the great age of Greek philosophy. In Aristotle the theoretic impulse of the Greek mind seems to have exhausted itself, and the post-Aristotelian or third period of Greek philosophy was mainly inspired by ethical and religious needs, and is occupied in developing a theory of life and conduct. The Stoics, Epicureans, and Sceptics, and later the Neoplatonists with their religious mysticism, carry on the tradition of philosophy till the downfall of the Roman empire and the death of Boethius. After the so-called dark ages Mediæval Philosophy may be said to begin in the 9th century with John Scotus Erigena, who is really a Christian Neoplatonist. Mediæval philosophy is mainly the application of the Aristotelian logic to the doctrines of the church, and latterly (when the other treatises of Aristotle became known in western Europe) exhausted itself in an elaborate attempt to harmonise the philosophy of Aristotle with Christian theology. Anselm and Abelard in the earlier period, Albertus Magnus, Thomas Aquinas, Duns Scotus, and William of Ockham in the later, are probably the greatest and most representative names of the Scholastic philosophy. The Renaissance put an end to Scholasticism, and led, in the 15th and 16th centuries, to various attempts to revive the systems of the older philosophers and to strike out new paths; but the age was one of transition, and no effective beginning was made in Modern Philosophy till the commencement of the 17th century. Bacon's *Novum Organum* was published in 1620 and Descartes' *Discourse on Method* in 1637. Bacon's investigations were mainly logical and methodological, and Descartes was the real founder of modern philosophy. Cartesianism was developed on the Continent into the great monistic system of Spinoza, from which the monadistic or individualistic theory of Leibniz was a reaction. In England philosophy took an epistemological and even psychological direction with Locke, and this was continued by Berkeley and Hume, who developed Locke's dualism into subjective idealism and scepticism respectively. Hume's sceptical analysis of knowledge gave rise by revision to the Critical philosophy of Kant, which combines elements both from the Continental to the English line of thought. From it sprang the idealistic developments of German thought in Fichte, Schelling, and Hegel, and also the realistic systems of Schopenhauer and Hartmann. Herbert and Lotze represent a realism of a more individualistic cast, which represents the continued influence of Leibniz. Scottish philosophy has maintained the reality of knowledge and the dualism of experience in answer to the scepticism of Hume, but like English philosophy generally has been mainly psychological in character. It offers in this way no parallel to the great metaphysical systems which have succeeded one another in Germany. But Sir William Hamilton's doctrine of the relativity of knowledge, based on elements of Kantian thought, became in the hands of Herbert Spencer the foundation of modern Agnosticism. Spencer also continues the empiricist tradition of English philosophy, to which he gives a wider scope by grafting upon it a theory of cosmic evolution. Recent developments of philosophy have been strongly influenced by biological conceptions. They lay stress on action as the fundamental fact in human experience, and tend to treat the intellect as the practical instrument of the will in the service of life. This tendency is exemplified in the widely-branching movement known as Pragmatism, and in Bergson's *Creative Evolution*. The most prominent movements within the last few years have been the New Idealism of the Italian philosophers, Croce and Gentile, largely based on Kant and Hegel but with important

differences of emphasis, and the New Realism, represented in England by Professor Alexander and in America by Holt, Montague, Periy, and others.

The best general histories of philosophy are by Erdmann, Ueberweg, Schwiegler, and Wendelband, all accessible in English translations. The works of Zeller, Gomperz, Burnet, and Adamson are authoritative in ancient, and those of Höffding, Falkenberg, and Adamson in modern philosophy. Rogers's *Students' History of Philosophy* is a well-executed survey. See also the articles on the various philosophers and systems, &c.

Philostratus, the name of several Greek sophists and rhetoricians, of whom the most famous was born probably about 181 A.D., studied under Proclus at Athens, and became a member of the learned circle that gathered round the Empress Julia Domna at Rome. He was alive, according to Suidas, in the time of the Emperor Philip (244-249). He wrote an idealised life of Apollonius of Tyana; the *Lives of the Sophists*, a series of bright and interesting sketches; and amatory and somewhat strained *Epistles*, interesting as the source of Ben Jonson's 'Drink to me only.' To another Philostratus, his nephew, is ascribed *Imagines*, a description of real or imaginary pictures; and to a third further *Imagines*. For the *Apollonius* (q.v.) see Conybeare's text and translation (1912) and Phillimore's (1912), who holds that the author was not a Lennian.

Philpotts, HENRY. See PHILLPOTTS.

Philtre (Gr. *philtion*, 'love charm'). A superstitious belief in the efficacy of certain artificial means of inspiring and securing love seems to have prevailed from very early times; love-charms and potions were in continual use among the Greeks and Romans. Their composition is uncertain, but there is no doubt that certain deleterious herbs and drugs were among their chief ingredients, magic rites being employed. Thessaly produced the most potent herbs, and her people were said to be the most skilful practisers of magic arts, whence the well-known 'Thessala philtia' of Juvenal (vi. 610). These potions were violent and dangerous in operation, and often caused weakening of the mental powers, madness, and death. Lucretius is said to have been driven mad by a love-potion, and to have died by his own hand in consequence. In the corrupt days of the Roman empire a regular trade in love-charms of all kinds seems to have been carried on chiefly by women. Philtres seem to have been used during the middle ages; and in the East belief in their power lingers down to the present day.

Phips, or PHIPPS, SIR WILLIAM, governor of Massachusetts, was born at Woolwich, Maine, on 2d February 1651, one of the twenty-one boys in a family of twenty-six children. He was successively a shepherd, a carpenter, and a trader, and in 1687 recovered from a wrecked Spanish ship off the Bahamas bullion, plate, and treasure valued at £300,000; this gained him a knighthood and the appointment of sheriff of New England. In 1690 he captured Port Royal (now Annapolis) in Nova Scotia, but failed in the following year in a naval attack upon Quebec. In 1692, through the influence of Increase Mather (q.v.), he was appointed governor of Massachusetts. He changed the manner of the wretched persecutions by appointing a commission of seven magistrates to try all such cases. He died on 18th February 1695 in London, whither he had been summoned to answer certain charges of arbitrary conduct. See Life by B. Bowen in Sparks's *American Biography* (1856).

Phiz. See BROWNE (HABLOT K.).

Phlebitis (Gr. *phleps*, *phlebos*, 'a vein'), inflammation of the veins, although seldom an original disease, is a frequent sequence of wounds, and is not uncommon after delivery, or in varicose veins. The disease is indicated by great tenderness and pain along the course of the affected vessel, which feels like a hard knotted cord, and rolls under the fingers. See VEINS, WOUNDS.

Phlebolites, or **PHLEBOLITHS** (Gr. *phleps*, 'a vein,' and *lithos*, 'a stone'), are calcareous concretions formed by the degeneration of coagulations in veins, or occasionally originating in the coats of the vessel.

Phlebotomy, or **VENESECTION**, is, as applied to human beings, treated at BLEEDING. The abstraction of blood was at one time considered the best and only remedy for the various diseases of horses and cattle, but at the present time it is comparatively rarely performed, except by veterinarians of the older school; but it is useful in subduing acute congestions, such as of the brain, in parturient apoplexy, congestion of the lungs, acute inflammation of the bladder, &c. The vessel selected for the operation is usually the superficial jugular vein, which in cattle is large and loosely situated under the skin of the neck.

In consequence of the mobility of the tissues surrounding the vein it cannot in cattle, as in horses, be raised and made sufficiently tense without the use of a cord tied round the animal's neck below the seat of the intended operation. This cord should be from $\frac{1}{4}$ to $\frac{1}{2}$ inch thick, pulled tight enough to arrest the flow of blood and cause the vein to become distended and tense. It should then be opened with the fleam and 'blood stick,' so as to pierce the skin and vein at one blow.

When a sufficient quantity of blood has been abstracted, say from 3 to 6 or even 8 quarts, the cord is slowly slackened so as to prevent a vacuum and the ingress of air into the vein, the lips of the wound brought into opposition and maintained there by a pin pushed through them, and around it twine or tow is twisted in the form of a figure of 8. The pin should not be removed for at least thirty hours.

Phlegethon (i.e. 'the Flaming'), a river of the infernal regions, whose waves rolled torrents of fire. Nothing would grow on its scorched and desolate shores. After a course contrary to the Coeytus (q.v.), it discharged itself, like the latter stream, into the Lake of Acheron.

Phlegraean Fields. See AGNANO, AVERNUS, POZZUOLI.

Phleum. See TIMOTHY GRASS.

Phloem. See BAST.

Phlogiston (Gr. 'combustible') was the term employed by Stahl, professor at Halle, in his *Zymoterchia Fundamentalis* (1697), to designate a hypothetical element which, by combining with a body, rendered it combustible, and which occasioned combustion by its disengagement, there being left, after its evolution, either an acid or an earth. The phlogistic theory held undivided sway in chemistry until the time of Lavoisier, who substituted for it the theory of oxygenation (1775-81), and was maintained by a few chemists, especially Priestley, till the beginning of the 19th century. According to it, sulphur was composed of sulphuric acid and phlogiston; lead, of the calx or earth of lead and phlogiston; &c. In consequence of the general adoption of the phlogistic theory, when Priestley, in 1774, discovered oxygen, and when Scheele, a little later, discovered chlorine, the names these chemists gave to their discoveries were *dephlogisticated air* and *dephlogisticated marine acid*. See CHEMISTRY.

Phlox, a genus of plants of the family Polemoniaceæ distinguished by a prismatic calyx,

salver-shaped corolla, and unequal filaments. The species (30 or so) are mostly perennial plants with simple leaves, and mostly natives of Siberia, eastern United States, and North America. A number of species are common in British flower gardens. It is a favourite genus with florists, and many very fine varieties have been produced.

Phocæa, the most northerly of the Ionian cities in Asia Minor, originally a colony from Phocis, headed by two Athenians, stood on a peninsula between the gulfs of Elais and Smyrna, and had an excellent harbour. The Phocæans were distinguished among the Greeks for their nautical enterprise.

When the city was besieged by the Persians in the time of Cyrus, many of its inhabitants emigrated to Corsica; Massilia (Marseilles) was a Phocæan colony. The old city survived into the later empire; the Genoese had a colony there in the middle ages to exploit the alum mines. The modern town is Eski Focha.

Phocæna. See PORPOISE.

Phocas, a tyrannical emperor of Constantinople (602-610). He was deposed and executed. See BYZANTINE EMPIRE.

Phorida. See SEAL.

Phocidia. See PHOCIS.

Phocion (Gr. *Phokion*), an Athenian general, was born about the end of the 5th century B.C. He was of humble origin, but studied under Plato, Xenocrates, and perhaps Diogenes also. Phocion first attracted notice in the great sea fight at Naxos (376), where he commanded a division of the Athenian fleet. In 351, along with Evagoras, he undertook the conquest of Cyprus for the Persian monarch, Artaxerxes III., and was completely successful. In 341 he was successful in crushing the Macedonian party in Eubœa and in restoring the ascendancy of Athens. Two years before this he had achieved a similar result at Megara; and in 340, sent to the aid of the Byzantines against Philip, he forced Philip to abandon the siege, and even to evacuate the Chersonesus. Nevertheless, he advocated, even in the midst of his triumphs, the establishment of better relations with the enemy, for he had come under the influence of the philosophical reaction in favour of monarchy instead of a democracy of petty aims and degraded character. He had come to see that a voluntary acquiescence in the supremacy of an enlightened ruler was better for Athens and for Greece than a hopeless struggle in defence of a political system that had lost its virtue. His advice was not taken; but the fatal battle of Charonea, only two years afterwards, in which the independence of the Greek republics was lost for ever, proved its soundness. After the murder of Philip in 336 we see him struggling at Athens to repress what appeared to him the reckless desire for war on the part of the fanatical patriots, on account of which he was regarded as a traitor; but his personal honour is above

Phlox paniculata (var.).

suspicion. On the death of Alexander in 323 the aged Phocion endeavoured, but in vain, to hinder the Athenians from going to war with Antipater. After Antipater's death he was involved in the intrigues of Cassander, the rival of Polyperchon, and was forced to flee to Phocis, where Polyperchon delivered him up to the Athenians. He was condemned by 'a mixed mob of disfranchised citizens, foreigners, and slaves' to drink hemlock. His body, flung unburied over the borders of the state, was carried by some of his friends to Eleusis, and buried there. The Athenians soon began to raise monuments to his memory. His life was written by Plutarch and Cornelius Nepos. See Jacob Bernays, *Phocion und seine neueren Beurtheiler* (1881) and G. Coleridge in *Nineteenth Century* (March 1923).

Phocis, PHOCIDIA, a province of ancient Greece, west of Boeotia, and bounded S. by the Gulf of Corinth. The greater part of the country is occupied by the mountain-range of Parnassus (q.v.). The state derives its chief historical importance from possessing the famous oracle of Delphi (q.v.). During the Peloponnesian war the Phocians were close allies of the Athenians. In the time of Philip of Macedonia they were involved in a ten years' war, on account of their opposition to a decree of the Amphictyonic Council, concerning the use of a piece of land belonging to the temple of Delphi. This war, commonly known as the Sacred or Phocian War, ended disastrously for the Phocians, the whole of whose cities (twenty-two in number) were destroyed, with one exception, and the inhabitants parcellled out among the hamlets. Phocis and Phthiotis form a province of modern Greece.

Phœbus (i.e. 'the Bright'), an epithet, and subsequently a name, of Apollo. It had reference both to the youthful beauty of the god and to the radiance of the sun, when, latterly, Apollo became identified with Helios, the sun-god. See APOLLO, HELIOS. Artemis (q.v.) was called *Phæbe*.

Phœnicia, the *Phœnice* of the Greeks, the *Phœnicie*, or (in rare cases) *Phœnicia*, of the Romans, was a tract of country lying to the north of Palestine, along the coast of the Mediterranean Sea, bounded by that sea westwards, and eastwards extending to the mountain crests of Bargylus and Lebanon. The limits of the tract northward and southward are variously stated by ancient authorities, and no doubt varied at different periods; but modern researches seem to indicate that the actual Phœnician occupation did not extend beyond Laodicea (Latakia) on the north and Acre, or at the furthest Carmel, on the south. This would give the coast line a length of about 200, or, counting main indentations, of 230 miles—a fair mean between the 120-300 miles of different writers. The width between the coast and the mountain-ridges of Bargylus and Lebanon varies from 8 or 10 to 25 or 30 miles, perhaps averaging 15 miles. The area of Phœnicia proper may thus be reckoned at about 3000 sq. m. The tract included within these limits is one of a remarkably diversified character. Lofty mountain, steep wooded hill, chalky slope, rich alluvial plain, and sandy shore succeed each other, each having its own charm, which is enhanced by contrast. The sand is confined to a comparatively narrow strip along the seacoast, and to the sites of ancient harbours now filled up. It is exceedingly fine and of excellent siliceous quality, especially in the vicinity of Sidon and at the foot of Mount Carmel. The most remarkable plains are those of Acre, Tyre, Sidon, Beirut, and Marathus—none of them very extensive, but richly fertile, and capable of producing, under any tolerable system of cultivation, luxuriant crops. The hilly region forms generally an intermediate tract

between the high mountains and the plains; but not unfrequently it commences at the water's edge, and fills with its undulations the entire space, leaving not even a strip of lowland. This is especially the case in the central region between Beirut and Arka, opposite the highest portion of the Lebanon; and again in the north, between Cape Posidimm and Jebel, opposite the more northern part of Bargylus. The hilly region in these places is a broad tract of alternate wooded heights and deep romantic valleys, with streams murmuring amid their shades. Sometimes the hills are cultivated in terraces, on which grow vines and olives, but more often they remain in their pristine condition, clothed with masses of tangled underwood.

From the hilly tract, which increases in elevation as it recedes from the shore, rise the two great mountain-regions, separated by a clearly-marked depression in 34° 35' lat. nearly, down which runs the river Eleutherns. The more northern of the two was known to the ancients as Bargylus (Jebel Nusairiyeh). But the glory of Phœnicia is Lebanon. Extended in a continuous line for a distance of 130 miles, with an average elevation of from 6000 to 8000 feet, and steepest on its eastern side, it formed a wall against which the waves of eastern invasion naturally broke. The flood of conquest swept along its eastern flank, down the broad vale of the Lik'a over Galilee, and the western lands were, in the early times at any rate, but rarely traversed by a hostile army. This western region it was which held those inexhaustible stores of forest trees that supplied Phœnicia with her warships and her immense commercial navy; here were the most productive valleys, the vineyards and the olive-groves; and here, too, were the streams and rills, the dashing cascades, the lovely dells, the deep gorges, and the magnificent cedar-trees which gave her the palm over all the surrounding countries for variety of picturesque scenery. The seacoast is but slightly indented, and possesses but few prominent headlands. The most important are Carmel, if that may be reckoned to Phœnicia, and Ras el Abiad, 10 miles south of Tyre, where a very ancient caravan route runs along a passage cut through the rock. Natural harbours were wanting, except where littoral islands offered a protection from the prevalent winds, as at Tyre and Aradus; elsewhere nature provided nothing better than open roadsteads; and the famous harbours of the Phœnicians were all of them the work of art.

The geology of Phœnicia is tolerably simple. Both Bargylus and Lebanon are longitudinal ranges of the early Cretaceous limestone, a limestone that is soft and pliable, very easily worked, but wanting the qualities needed for the imitative arts. This simple formation is, however, intruded upon by disturbances of igneous origin, especially in the lower ridges. On the whole, the predominant formation is a greasy or powdery limestone, and this is the sole material of the higher ranges. The softness of the general material facilitates the formation of a rapid vegetation and the accumulation of vegetable soil, which, washed down by the rivers, covers the more open valleys and the plains which fringe the coast with an alluvium of the most productive character. Its mountain-regions must always have furnished Phœnicia with an inexhaustible supply of excellent timber—fir, pine, and cedar: the lower slopes of its hills were admirably adapted for the cultivation of the olive and the vine, while its maritime plains were equally fitted for the growth of corn and of almost every kind of fruit and vegetable. In mineral products it may have been deficient; but the sandstone of the Lebanon is often largely impregnated with

iron, and some strata towards the southern end of the mountain are said to produce as much as 90 per cent. of pure iron ore. An ochreous earth is also found in the hills above Beirut, which gives from 50 to 60 per cent. of metal. Coal, too, has been found in the same locality. Finally, the geologist Fraas succeeded in finding innumerable traces of amber-digging on the Phœnician coast; whence it may be gathered that rare substances were also in the early times among Phœnician products.

It is now recognised that the Phœnicians are to be included among the Semites (q.v.). In Genesis x., however, they are not assigned to Shem, and Sidon is called the first-born of Canaan and a descendant of Ham (verses 6, 15). But the chapter is not framed on strict ethnographical lines, and it gives effect to the hostility to Canaan which reappears in the curse upon Canaan (chap. ix. 25 f.) and in the contemptuous references elsewhere to the Canaanites. Moreover, not only was there a very close relationship between Phœnicians and Canaanites, intercourse between Canaan, Phœnicia, and Egypt both by land and by sea goes back to a remote date. The genealogy of the 'sons' of Noah (Gen. x.) certainly expresses the feeling that the Phœnicians and Canaanites were no true kinsmen of the sons of Shem, and therefore of the Israelites, but from time to time the bond between Phœnicia, Samaria, and Jerusalem was particularly close, and the enmity of the Tyrians could be regarded as a rupture of the 'brotherly' covenant between Phœnicia and Israel (Amos, i. 9).

In point of fact two different traditions of the origin of the Phœnicians, though recorded by late writers, unmistakably associate them with the other Semites. According to Herodotus, Strabo, Pliny, and others, they dwelt anciently on the shores of the Persian Gulf (Erythraean Sea), whence they crossed by land to Syria, and settled on the coast of the Mediterranean. Herodotus (vii. 89) declares this to be their own account of themselves, and Strabo says that there was a similar tradition among the inhabitants of the gulf, who showed, in proof of it, Phœnician temples on some of the islands. Justin, on the contrary, in his epitome of Trogon Pompeius, declares that they were driven out of their country by an earthquake, and passed to the Mediterranean from the 'Syrian lake,' or Dead Sea. This latter version of the story has been connected by some with the destruction of the Cities of the Plain recorded in Genesis. Whichever account be preferred, it would seem that the Phœnicians regarded themselves as immigrants into their country, and not (like most ancient nations) as aboriginals.

The language of the Phœnicians belongs to the North Semitic branch, which includes Hebrew, Moabite, and an ancient dialect found in the extreme north of Syria. The same common language can be traced on cuneiform tablets from Phœnicia and Palestine of the 14th century B.C., in inscriptions at Byblus (dated to the 13th century); then, forming a distinct dialect, Phœnician is found on inscriptions of the 8th and later centuries, it undergoes various changes in the Punic and Neo-Punic inscriptions of Carthage, &c., and fragments survive in the *Pœnulus* of Plautus. It was still in popular use in St Augustine's day (5th century A.D.). Corresponding to this old common language, which in Palestine was gradually replaced by Aramaic, there was a common type of alphabet which, in time, broke up into Phœnician (Old Hebrew, &c.) and Aramaic branches. This is the alphabet which through the Phœnicians was spread among the Greeks, Etruscans, Romans, &c., and they have often been regarded as its inventors. However, the problem of the Alphabet (q.v.) is still under discussion. If an inscription found by

the French at Byblus is rightly ascribed to the 13th century B.C., the characters are far removed from any Egyptian or other suggested source, and a curious script found by Sir Flinders Petrie in Sinai (c. 1500 B.C., or perhaps c. 1800), which seems to be a link between the Egyptian hieroglyphs and the Phœnician linear alphabet, is no less removed from the oldest North Semitic characters. The main facts are that c. 1400 B.C. the cumbersome cuneiform (Babylonian) was the language of intercourse over Egypt and south-west Asia (including the Hittites), while the Cretans, the dominant people of the eastern Mediterranean, had pictographic and linear writing of their own. But in some way a simple alphabet of twenty-two characters arose, and in due course spread among Semites and Greeks, and the Phœnician traders in this, as in other respects, seem to have been the disseminators rather than the inventors.

Long before Phœnician history begins, the coastlands of Syria and Palestine had been in close touch with the rest of the Levant. But whatever part Phœnicians played as sailors or traders, it is very unlikely that the Phœnician ports were of any political significance prior to the fall of Crete and the decline of Egypt. From the 'Ammurru Letters' (found at el-Amarna, see vol. iv. p. 241, col. 2) it is seen how they were at the mercy, not only of sea-pirates, but also of the great powers with whose fortunes they were closely bound up. The period (c. 1400-1350 B.C.) was one of widespread unrest, and a powerful Amorite state (centring about the Lebanon) was actively intriguing against Egypt. Then, as repeatedly happened later, all the petty peoples were divided among themselves, and already Tyre and Sidon were rivals. Subsequent events show how the Hittites gradually extended their influence to the south; and then, as the greater powers weakened, sea-peoples broke over the coastlands, and the Philistines (q.v.) were not the only strangers to settle down along the coast. It is about the 12th century B.C. that conditions were favourable for the establishment of new states, and tradition (in Justin, xviii. 3) not unjustly recognises a landmark when Tyre is said to have been founded a year before the Fall of Troy (the tradition date of which is c. 1183). Undoubtedly there had been Semites (Semitic-speaking people) in the land called 'Phœnicia'—and even the foreign Philistines, further south, themselves became Semitised—and it is difficult to distinguish between Semitic Phœnicians and the people of Phœnicia, many of whom were invariably of foreign origin, but in any case the 12th century seems to mark a new stage in the history of Phœnicia, Syria, and Palestine.

About this time (c. 1115-1100 B.C.) an Egyptian account of the visit of an envoy to Byblus to procure cedar vividly depicts the haughty independence of the city-state, although the indebtedness to Egypt and Egypt's god Amun is clearly admitted. Mention is made also of a great Phœnician fleet; and since, in return for cedar, Egypt sends gold, silver, linen, hides, rope, and rolls of papyrus, there is little doubt that Phœnician trading-activity was in full swing. At one time or another several Semitic words made their way into Greek: names of products (byssus, libanos [incense], cane, cumin), also camel and sack, and the word for 'pledge' (*arrabon*, Fr. *arrhes*); and the trade in papyrus is of special interest, since the Greek name for it (*biblos*) was derived from Byblus (like 'parchment' from Pergamum), and from it, in turn, is ultimately derived the word 'Bible' (cf. vol. ii. p. 119, col. 2). For long the Phœnicians must have been content with trading-posts, settlements, and factories, so that 'the history of Phœnician trade and colonisation presents many analogies with those of Portugal and Holland' (Eduard Meyer). Hence

it was that in time the places were swallowed up, or, under favourable conditions, could assert political supremacy, as, notably, in Cyprus, and in Carthage and elsewhere in North Africa.

The Phœnicians appear as navigators in the earliest Greek (Homer, *Odyssey*, xv. 415-484), and in some of the earliest biblical (1 Kings, v. 9) sources. They were regarded as familiar with the sea in times anterior to the Trojan war (Herod. i. 1). Their ships, though small, according to our ideas, were well built, and admirably fitted up and arranged (Xen. *Econom.* sect. 8). For trading purposes they employed ships of a broad, round make (*γαλῆες*), but in war they used galleys of a considerable length, which were ordinarily impelled by oars, the rowers sitting on a level, or else in two ranks, one above the other, or sometimes in three. The earliest representations of Phœnician vessels which have come down to us are in the sculptures of Sargon and Sennacherib (c. 700 B.C.); those of the latter showing a double tier of rowers. The crews of these vessels do not appear to exceed the number of twenty-five; but the Phœnician war-galleys in the fleet of Xerxes (480 B.C.) carried a crew of 200 sailors, besides thirty men-at-arms (Herod. vii. 184). Phœnician trade was in part a land trade conducted by travelling companies of merchants, in part a traffic by sea. Of the land trade the best account which we possess is that given in the 27th chapter of Ezekiel (verses 3-24), by which it appears that this traffic extended over the greater part of western Asia, including northern Syria, Syria of Damascus, the land of Israel, Arabia, Mesopotamia, Assyria, Babylonia, parts of Armenia, and much of central Asia Minor. Northern Syria furnished the Phœnician merchants with linen, embroidery, and precious stones. Israel supplied food, oil, balsam, and honey, and agents collected the homespun cloth (Prov. xxxi. 24). Caravans travelling by way of Hamath or Damascus would feed the ports, though the more northerly road running east and west to India and Asia Minor would usually lie outside their reach. Arabia provided spices, ivory, and ebony, precious cloths, jewels, and gold; but the Arabian trade might otherwise pass through Gaza to the Levant. Accordingly, a powerful Phœnicia, when on friendly terms with Israel and with Edom, would seek to exploit the trade that reached the Gulf of Akabah from East Africa and India. Tarshish (Tartessus), in south-west Spain, was so regularly visited for its silver and other mines (of proverbial richness) that 'Tarshish-ships' became a name of wide application, like our 'East Indianer.' Copper was obtained from Cyprus (whence the name), and tin from the Scillies; despite late and fanciful tradition, there is no definite evidence that the Cornish mines were worked by Phœnicians. They collected the *marex* shell-fish in order to obtain the brilliant dyes for the textiles wherein they excelled. Glass (q.v.), said to have been discovered accidentally on the Phœnician coast, was known to the Egyptians centuries before the prominence of the Phœnicians; though the excavations of the siliceous sand near Sidon and in the Bay of Acre may have given rise to the tradition. In any case, the Phœnicians passed on the fine Egyptian glass.

Apart from early Egyptian representations of objects in precious metal, vases, and the like, brought by vassals from Phœnicia and Syria, most of the examples of Phœnician workmanship come from the 8th century and later, and reflect Egyptian and Mesopotamian influence. Phœnician art is clumsy, eclectic, with little originality. The Phœnicians were a money-making merchant-folk, and on this account disliked. In the Persian age and later, Greek influence became exceedingly strong, and it is this persistent indebtedness to

external influence which makes it improbable that they even invented the alphabet. Of their literature little is known. The 'Amarna Letters' from Byblus, Beirut, Sidon, and Tyre (about seventy in all) are, as regards style, not dissimilar from those of Palestinian origin; the way in which the writers address their divine overlord, the king of Egypt, points to a wealth of idea which sometimes reminds one of the Old Testament. No doubt the archives of Tyre, which Menander of Ephesus translated into Greek (Josephus, *c. Ap.* i. 17 sq.), would be mere chronicles; but the Greek fragment of a translation of the voyage of Hanno along the west coast of Africa (c. 500 B.C.), if authentic, would show that African Phœnicians could write interesting books of travels. Latin writers speak highly of Hiempsal, Mago, Hamilcar, and others, who composed works on history and geography. One, Mochus of Sidon, a reputed founder of Eastern philosophy, had a modified form of a Sidonian cosmogony which Damascius took over and gave a neo-Platonic interpretation, and another cosmogony from Philo of Byblus is preserved by Eusebius. Both represent a tendency to prove the superiority of Eastern lore; and Philo, in particular, is characterised by his effort, following Euhemerus, to explain mythology as misunderstood history by mingling the deities into men and women who had been deified after death ('Euhemerism'). Both, though differing in details, agree in substance, and when allowance is made for their strange philosophical dress, they are found to contain some valuable traces of the old Phœnician religion.

The Phœnicians, like the Semites, were a people in whose minds religion and religious ideas occupied a very prominent place. In all their cities the temple was the centre of attraction, and the piety of the citizens adorned every temple with abundant and costly offerings. The monarchs who were at the head of the various states showed the greatest zeal in continually maintaining the honour of the gods, repaired and beautified the sacred buildings, and the kings and queens were often the priests and priestesses of the deity. The coinage of the country bore religious emblems, and proclaimed the fact that the cities regarded themselves as under the protection of this or that deity. Both kings and their subjects commonly bore religious names—names which designated them as the worshippers, or placed them under the atonement, of some god or goddess. *Abd-alomni*, *Abd-astarte*, *Abd-asiris*, *Abdi-milkut*, *Abd-eschmun* are names of the former kind; *Abihani* ('Baal is father'), *Itho-bal* ('With him is Baal'), *Baleazar* ('Baal protects'), names of the latter.

The Phœnician ships carried images of the gods in the place of figureheads (Herod. iii. 37). Wherever the Phœnicians went they bore with them their religion and their worship; in each colony they planted a temple or temples, and everywhere throughout their wide dominion the same gods were worshipped with the same rites and with the same observances. The ordinary term for the god is *Baal* (fem. *Baalath*); other titles are *Adon* 'lord,' whence the famous *Adonis* (q.v.), whose actual name is unknown, and *Milk*, *Melek*, 'king' (cf. the Old Testament *Molech*). We hear of a *Baal* (of) Sidon, (of) Lebanon, &c.; the *Baal* of Tyre was called *Melkart*, which simply means 'king of the city'; he was identified with *Heracles*. *Baal Hammon*, common in North Africa, was the god of (i.e. inhabiting) the pillar, or he was the glowing, burning god (perhaps Saturn), and the name may also have been associated with Jupiter Ammon. Of special interest is the *Baal* of the Heavens (*Shamem*) or Sky-god, who became supreme, and was equated with the 'Most High Zens' of the Greeks. The *Baalath* of Byblus was known to the

Egyptians from an early date; she was no doubt an Astarte, whose name (in the Old Testament Ashtoreth) is the same as the Babylonian Ishtar. Of more distinctive names, Resheph (flame, lightning) was identified with Apollo, Anath (identified with Athene) was an ancient warrior-goddess, Tanith of Carthage (identified with Demeter and Artemis) is of perplexing origin. She is called 'the face of Baal,' i.e. a manifestation of the god, even as Astarte, who is represented as Isis, and identified with Aphrodite-Venus, is once called 'name of Baal.' Both usages find parallels in the Old Testament (Exod. xxxiii. 14, xxxiii. 21). The name of Sidon seems to preserve that of some 'hunting' god, and Dagon was probably some food-god (corn or fish as the case might be); Beirut, too, could be explained as 'food.' But while some names are entirely in accord with the intensely practical character of early and simple religion, tendencies to frame cosmic powers are to be recognised, especially in the Greek age, when, also, foreign deities take a more prominent place in the religion.

The gods were worshipped with perpetual sacrifice in their temples, with votive offerings and with festivals. A spring festival to Melkarth, 'The Baal of Tyre,' in the month Peritius (Joseph. *Ant. Jud.* viii. 9, sect. 3), and another to Ashtoreth called 'the braud feast' (Lucian, *De Dea Syria*, sect. 10), are especially noticed. Anciently it was not considered right to erect statues to the gods in their temples; but the practice was to represent them by conical pillars of stone or wood (Tacit. *Hist.* ii. 3). Two terrible rites particularly characterised the religion—human sacrifice and religious prostitution. A divine original was found for the former of these, El having in a time of great danger immolated his only son upon an altar to avert the evil wherewith the land was threatened. Henceforth such sacrifices were from time to time offered by the state when great disasters seemed impending, and individuals appeased the divine anger against themselves by the offering of their children. At Carthage, we are told (Diod. Sic. xx. 14), an image of El, made of metal, was heated to a glow by a fire kindled within it, and the victims, deposited by their parents in its arms, thence rolled into the fiery lap below. First born, and especially only sons, or virgin daughters, were deemed peculiarly acceptable to the divinities. The godhead, it was thought, demanded the holiest and most costly gifts possible; and this idea, which lay at the root of the child-sacrifice, may be regarded as also explaining the prostitution of virgins in the temples and groves of the 'Queen of Heaven,' which was certainly an established custom.

Phœnician history is very fragmentary. The friendship between Hiram of Tyre and the Israelite kings, David and Solomon (c. 1010-940), was marked by joint enterprise in trade, and the employment of Phœnician artisans to build Solomon's palace and temple testifies to the dependence of the inland state upon its more cosmopolitan neighbour. Close relations recur in the alliance between Ithobaal (or Ethibaal), priest-king of Tyre and Sidon, with Omri and Ahab of Samaria. Jezebel the daughter of the former, was married to Ahab, and their daughter Athaliah was married to Jehoram, son of the Judæan king Jehoshaphat, and for a short time reigned as queen-mother (c. 840). Both Ithobaal and Omri were usurpers and active monarchs, and once more there were joint trading-journeys. To the biblical writers the age of Ahab, and the alliance with Phœnicia and all it entailed, constitute a landmark; and it is a noteworthy fact that, while they record the drought broken after the famous scene on Mount Carmel and Elijah's prayer to the God of Israel, the native Phœnician historian Menander (cited by Josephus) knew of a

year's drought which, however, was broken by the supplication of the priest-king Ithobaal to his own god. It was the age of Assyrian aggression, and henceforth the Phœnician cities are often mentioned in the Assyrian records. Meanwhile the colonies were growing: first, Lixus in Mauretania, Gades (Cadiz), Utica—all ascribed by tradition to the 12th century. Some time later Botrys, north of Byblus, and Anza, in North Africa, are attributed to Ithobaal. Then a dispute between the young Pygmalion and his uncle Siharbas (Zacharbaal), who was married to his sister Elissa, or Dido (q.v.), led to the murder of the uncle, Dido's flight to North Africa, and the foundation of Carthage (q.v.). By the time of Tiglath-pileser III. (c. 732 B.C.) the wealth of Tyre can be gauged from the enormous tribute of 125 talents of gold imposed upon her. To this age belong the fragments of a bronze bowl dedicated to the Baal of Lebanon, which, until the recent discovery of the Byblus inscription, was regarded as the oldest specimen of Phœnician writing. In the next century Egypt, whose petty Delta-kings had been in regular intercourse with the Greek world, slowly waking up from her long sleep, began to entertain ambitions of recovering her influence over south-west Asia, and the history once more begins to be on a far-reaching international scale. In the new Egyptian-Assyrian rivalry Phœnicia remained generally faithful to its old Egyptian connections; but when, after the fall of Assyria (612 B.C.), Babylonia came to the front, and Nebuchadnezzar, at the battle of Carchemish (605 B.C.), defeated the hopes of Egypt, Phœnicia passed under a new master, though Tyre held out and endured a thirteen-year siege (from c. 586 B.C.), a crowning proof of her natural strength. Then, in due course, as the Persians overcame the new Babylonian empire, Phœnicia again changed masters, and her fleet was the chief mainstay of the Persian dynasty in its wars in the west. Her history thus becomes part of that of Carthage and of Greece, and her colonies were stronger than the mainland. Sidon now surpassed Tyre in importance, so that her king actually took precedence next to the great king of Persia himself. Not confined like Tyre geographically, Sidon was a more cosmopolitan city, the seat of the Persian satrap, and with strong partiality for Greek culture. This is most marked in the 4th century B.C., when we have a series of royal Sidonian inscriptions extending into the middle of the 3d century (an earlier date is improbable), invaluable for the light they throw upon the strength of native Phœnician belief and usage in spite of the influence of both Greece and Egypt. And a similar story is told by the coins, even of the Roman period.

Apart from the admirable though naturally now rather antiquated history of Phœnicia by George Rawlinson (1889), some of whose original article to this *Encyclopædia* is here retained, the subject is not usually treated by itself. Reference may be made for (1) geography, topography, &c. to Bader's *Palæstine*; (2) history, &c. to the usual larger histories; (3) religion, to Lagrange, *Études des Rel. Sém.* (Paris, 1905); Baudissin, *Adonis und Esman* (Leipzig, 1911); and J. G. Frazer, *Adonis, Attis, Osiris* (London, 1919); (4) inscriptions, G. A. Cooke, *North-Semitic Inscriptions* (Oxford, 1903); (5) coins, G. F. Hill [Coins of the British Museum]; see also E. Meyer's article 'Phœnicia' in *Ency. Biblica*, and below, article *SMIRNA*.

Phœnix, the name of a mythical Egyptian bird, supposed by some to be a kind of plover, by others to be the sacred *hennu*, or nycticorax, while some regarded it as a kind of eagle. The Phœnix legend presents great variations. According to some writers it visited Egypt after the death of its father, and buried its parent in the shrine particularly dedicated to it at Heliopolis, putting the body

into an egg or case made of myrrh. Another account is that the Phoenix, when about to die, made a nest for itself in Arabia, from which a new Phoenix sprang of itself. This bird proceeded to Heliopolis, and there burned and buried its father. But the more popularly-known version is that the Phoenix buried itself, and a new and young Phoenix sprang from the ashes. The Phoenix was, according to the most authentic accounts, supposed to visit Egypt every 500 years; the precise period, however, was not known at Heliopolis, and was a subject of contention till its appearance. Some chronologists uphold the connection of the Phoenix period with that of the Sothic cycle, as well as the statement that it designated the soul and the inundation of the Nile. A great difference of opinion has prevailed about the Phoenix period—a cycle generally of 500 years, but varying also from 250 to 7000 years. Lepsius makes it a cycle of 1500 years. The Phoenix was fabled to have appeared four times in Egypt. A fellow of an Oxford college argued in 1840 in favour of the existence of the phoenix (see *Notes and Queries*, 22d December 1882). He followed Clement, Tertullian, Epiphanius, and other church fathers.

Phoenix. See DATE PALM and PALM.

Phoenix, capital of Arizona, in the Salt River Valley, centre of a farming, grazing, and mining district. Pop. 30,000.

Phoenix Park. See DUBLIN.

Phoenixville, a town of Pennsylvania, on the Schuylkill River, 28 miles by rail N.W. of Philadelphia. Here are the extensive works of the Phoenix Iron Company, besides factories for under-clothing, silk, and much else. Pop. 10,500.

Pholas, a genus of marine boring bivalves, of the family Pholadidae. The shell is thin but hard, gapes at both ends, and has accessory valves. The two principal valves are beset with inequalities, producing a rasp-like structure. By twisting or rocking on the fulcrum of the sucker-like muscular

A piece of rock bored by *Pholas*.

foot and bringing the teeth or spines of the shell-valves against the substratum, these boring molluscs make cylindrical holes in the rocks or in wood. Over thirty living species are known—e.g. the common *Pholas dactylus*, popularly known as the *pidcock*. It is used both for food and bait. Some species are markedly luminescent. The allied genus *Pholadidea* is also represented on British coasts, and so is the wood-boring *Xylophaga*. To the family

Pholadidae also belongs the ship-worm, or *Teredo* (q.v.). See also BORING-ANIMALS.

Phonetics is that branch of the general science of Linguistics (q.v.) which is concerned with pronunciation in all its aspects. It is concerned notably with the manner in which speech-sounds are formed by the organs of speech, the ways in which speech-sounds are put into sequence so as to form words and sentences, their length (quantity) and stress (force accent) in connected speech, the rise and fall of the musical pitch of the voice, and the effects which speech sounds and sequences of speech-sounds produce on the ear.

The Applications of Phonetics.—It is at once evident that the science of phonetics has numerous practical applications. These include its application to (1) the learning and teaching of foreign languages; (2) the teaching of the mother-tongue; (3) the study of dialects; (4) the curing of individual speech defects; (5) the teaching of speech to the deaf; (6) the construction of alphabets for languages hitherto unwritten; (7) the construction of systems of writing for special purposes (e.g. systems of shorthand, alphabets for the blind, telegraphic codes); (8) philology.

It is not possible in this article to deal with all these applications of phonetics. The treatment of the subject will be confined mainly to its most important aspect—namely, the use of phonetics in the study of foreign languages.

Phonetics helps language learners both to pronounce and to understand foreign spoken languages better than is possible without phonetics. Ordinary language learners cannot hope to pronounce a foreign language perfectly unless the language has been subjected to 'phonetic analysis,' and the learner acquires the pronunciation by means of 'phonetic training.' By 'phonetic analysis' is meant the determination of the mechanism by which each sound of the language is uttered, and of the usage of the language in the matter of length, stress, and intonation; also the preparation of phonetic transcriptions (to show how the sounds are used in words and sentences). 'Phonetic training' includes (1) ear-training; (2) exercises for the organs of speech; (3) learning to use the right sound in the right place in connected speech; and (4) learning to pronounce the sounds and syllables of connected speech with the correct length, stress, and intonation.

Ear-Training.—The importance of ear-training for students of spoken languages cannot be over-estimated. There is only one satisfactory method of training the ear to recognise the speech sounds of a language. It is that a native teacher (or a teacher who pronounces as a native) should dictate meaningless words made up of sounds of the language. The learner writes these words by means of a phonetic transcription, and the teacher sees from what has been written whether the learner recognises accurately the various sounds of the language in different combinations. When the learner makes a mistake, the teacher repeats the word, firstly giving the pronunciation represented by the learner, and then with the pronunciation originally dictated. When the learner has heard the two pronunciations contrasted a number of times, he soon learns to distinguish the sounds with certainty. As the learner progresses, the teacher should (if possible) introduce sounds of the learner's mother-tongue, also cardinal vowels and sounds of other foreign languages. Those who contemplate undertaking phonetic analysis of languages not hitherto analysed should prepare themselves by thorough ear-training, comprising as many sounds as possible.

Training the Organs of Speech.—Those who wish to pronounce a foreign language properly must also learn to make all the speech-sounds of that lan-

guage. This is done by means of exercises for the organs of speech ('mouth gymnastics'). If a language has been phonetically analysed, the manner of forming every sound in it is known. This knowledge, supplemented when possible by a knowledge of the speech mechanism of the learner's mother-tongue, will suggest exercises which will enable him to produce accurately all the difficult foreign sounds both in isolation and in combination.

For example, the sound of French *u* in *lune* (phonetically [y])¹ is easily learnt by any one who knows that it is approximately the English sound of *ee* (phonetically [i]) said through rounded (pursed-up) lips. Control over this sound is facilitated by the exercise of alternating it with the English sound of *ee*, thus [iyiyiy . . .]. The Hindustani [ɪ] and [ʊ] are not difficult to those who know that the tip of the tongue must touch the edge of the upper teeth for the former, and must touch the hard palate for the latter. Control over these sounds may be acquired by practising rapidly tatātātā . . . and other combinations containing these sounds. The Japanese [ɸ] (as in *Fuji*) can be acquired by noticing that it is formed by the two lips, whereas the English [f] is formed by the lower lip against the upper teeth. Other foreign sounds are more difficult than those mentioned here, but a knowledge of the mechanism by which they are produced will always help the learner to improve his pronunciation, and will often make it perfect.

The Use of Phonetic Transcription.—Phonetic transcription is generally described as a system of writing which provides one symbol for every speech sound. A more accurate definition is given in the section on Theory of Phonetic Transcription (below). The following are the chief uses of phonetic transcription: (a) One of them has already been mentioned in connection with ear-training (see above). If the learner does not write the dictated words by means of a phonetic system, the teacher cannot tell whether he has recognised the sounds correctly, and cannot, therefore, give him the necessary ear-training practice. (b) Those who write about the theory of speech-sounds must necessarily have unambiguous phonetic symbols to represent the sounds with which they deal. (c) Phonetic transcription is the means of showing which of the sounds of a language are the appropriate ones to use in given words and sentences. Phonetic transcriptions, therefore, help the learner to use the right sound in the right place in connected speech. Thus foreign learners of English do not, as a rule, know when to use the 'strong' and 'weak' forms of such words as *and*, *from*, *have*. Phonetic transcription will, however, show them that *and* is reduced to [n] in *bread and milk* [brednmlk], *from* has its strong form [frʌm] in *Where does he come from?* but its weak form [frəm] in *He comes from London*, that *have* has its weak form [(h)əv] in *I should have thought so*, and so on. Phonetic transcription will likewise show in which cases the two values of French *eu* are used—e.g. the 'closer' vowel [ø] in *peu* [pø], *Meuse* [møːz], *feutre* [fɛːtr], and the 'open' vowel [œ] in *neuf* [nœf], *peur* [pœːr]. (d) Special phonetic signs may also be used to indicate length, stress, and pitch; such signs are essential for transcribing languages in which words are distinguished by any of these 'sound attributes,' though the utility of such signs is by no means confined to such languages.

The methods of teaching a normalised pronunciation of the mother-tongue to those who speak in a dialectal manner are similar to the methods used in teaching the pronunciation of a foreign language. So also are the methods of curing individual peculiarities of pronunciation (lispings, &c.).

¹ Letters enclosed in square brackets [] are phonetic symbols (International Phonetic System).

Phonetic Analysis of Languages.—The phonetic analysis of languages is carried out (a) by auditory methods, and (b) by experimental methods. Of these the auditory methods are the most important, and give by far the most useful practical results. Analysis by auditory methods can only be satisfactorily carried out by persons endowed with an exceptionally keen ear, who have been through a thorough course of general phonetics, and have thereby learnt to recognise and to make the sounds of numerous languages. Phonetic investigations into a language not hitherto analysed are carried out as follows: The investigator asks a native speaker to repeat, as many times as may be necessary, words and phrases containing the sounds to be analysed. Some of the sounds will prove to be already familiar to him; others may be closely related to sounds he already knows, while other sounds may be entirely new to him. To determine the mechanism of such sounds the investigator imitates them, and gradually adjusts his organs of speech until he produces the sounds to the satisfaction of the native. This, however, is not enough, since natives are only too often satisfied with approximations to the correct sounds, especially if the pronunciation is better than that usually heard from learners of their languages. The investigator must, therefore, test his native instructor by intentionally mispronouncing sounds in various ways. If the native is as well satisfied with any intentional mispronunciations as he is with the attempts at the real sound, the investigator will know that he cannot establish the formation of the sound with certainty with that native instructor. If, however, the native will not accept as correct the slightest deviation from a particular mode of production, then the investigator will be satisfied that the mode of production is the correct one. By similar procedure the investigator can establish the usage of the language in the matter of length, stress, and pitch.

By 'experimental methods' we mean analysis by means of specially designed apparatus, such as the phonetic kymograph, thin artificial palates, X-ray photography. These methods are useful as corroborating the results obtained by auditory methods, but they cannot supplant auditory methods. A short description of experimental methods will be found in Jones' *Outline of English Phonetics*, and in an article on 'Experimental Phonetics and its Utility to the Linguist,' by D. Jones in the *Proceedings of the Royal Institution*, 1919.

Sketch of Phonetic Theory.—In the following paragraphs we give a brief outline of the theory of phonetics. Speech, regarded from the point of view of the *hearer*, may for practical purposes be considered as being made up of sequences of sounds uttered by the speaker. Thus the words *san*, *thing* each strike the ear as being composed of three sound-qualities pronounced consecutively without any intervening silence; these sounds would be represented in phonetic transcription by [sən], [θɪŋ] respectively. In continuous speech the sequences of sounds are broken from time to time by silences. It is necessary for practical purposes to regard the silences of voiceless stop-consonants (see section on plosive consonants below) as particular cases of 'sounds.' The acoustic effects known as speech-sounds are also called *Phones*. Phones, then, are the effects produced on the ear by particular types of air vibration, namely vibrations which are set up when a person produces certain kinds of air currents by means of his organs of speech. (The term has also to be extended in the case of voiceless stops to the silence produced by causing air vibrations to cease.)

From the point of view of the *speaker*, speech may be regarded as successions of movements of

the organs of speech (larynx, vocal cords, soft palate, tongue, lips, &c.); these movements give rise to the acoustic effects known as phones. In continuous speech the sequences of movements are broken from time to time by rests. The complete movement or set of movements required to produce a phone is called a *speech-movement* or *Gest*. (This term has also to be extended so as to include the cessation of movement occurring in voiceless stops.) A phone may therefore be described as the acoustic effect of a *gest*.

A sequence of phones pronounced without pause may be termed a *speech-chain*. In other words phones may be regarded as the units of which a speech chain is composed. (It should be observed that the delimitation of these units is in some cases arbitrary and conventional, and that in consequence it is not possible to give a scientifically accurate delimitation of a phone.)

Phones and Phone-attributes.—It is convenient to restrict the meaning of the term phone to the 'tamber' or 'quality' of a sound emitted by the organs of speech. Every phone has, however, one or more of certain other characteristics known as *phone-attributes*. These characteristics are *length*, *stress*, and *voice-pitch* (see below). Our use of the term phone may be compared to the use of the terms 'tamber' or 'quality' as applied to musical instruments. We speak of the characteristic tamber of (say) a clarinet, though that tamber cannot exist apart from the length, force-accent, and pitch of every sound issuing from the instrument.

Phonetic Theory covers (1) the manner of production and the acoustic effect of every phone in any language or mode of speech; (2) the order in which phones are placed in uttering words and sentences; (3) the ways in which the various phones of any language may be grouped into what are called 'phonemes' (see below); (4) the usage of languages in the matter of phone-attributes. We will consider these matters in order.

The Organs of Speech.—The air-current required for producing phones is generally supplied by the lungs. Chiefly owing to the mobility of the lips, tongue, soft palate, and vocal chords, the passages through which the exhaled air may pass during speech are capable of taking a great variety of shapes. Different configurations or movements of the organs of phonation give rise to different phones or groups of phones. A section of the organs of phonation with the names of those parts which

Fig. 1.—The Organs of Speech.

are of particular importance in the study of speech is shown in fig. 1. It should be observed that the divisions marked on the tongue ('blade', 'front', and 'back') are arbitrarily chosen as being convenient for the purpose of the study of speech; they do not correspond to any physiological features of the tongue. The blade of the tongue is defined as that part which normally lies opposite the 'teeth-ridge' (the convex part of the roof of the mouth just behind the upper teeth); the 'front' and the 'back' are defined as the parts of the tongue which normally lie opposite the hard palate and soft palate respectively. The 'root' of the tongue is defined as that part of it which forms the front wall of the pharynx.

The vocal cords are like a pair of lips situated horizontally in the larynx. They can be (1) held wide apart so that when air is exhaled the sound known as 'breath' is produced; (2) brought close together so that when the air is expelled from the lungs they vibrate producing 'voice'; (3) closed completely, giving rise to the consonant known as the 'glottal stop'.

The false vocal cords (another pair of lips situated in the larynx just above the true vocal cords) can be brought together, though not throughout their entire length. Constriction of the false vocal cords gives rise to one type of 'whisper.'

Classification of Phones.—We distinguish two main classes of phones, Consonants and Vowels. Consonants are made by complete or partial closure at one or more parts of the air-passage with or without accompanying voice. Vowels are voiced sounds which require that the air should issue in a continuous stream through the centre of the mouth, there being no narrowing sufficient to give rise to audible friction. (See in greater detail Trofimov and Jones, *Pronunciation of Russian*, chap. iv.)

Classification of Consonants.—Some consonants are 'voiced'; others are 'breathed' (also called 'voiceless'). That is to say, in producing some consonants the vocal cords are made to vibrate and produce voice, while in the case of others the vocal cords are kept wide apart. To every voiced consonant there corresponds a breathed consonant; thus the breathed phone [f] corresponds in articulation to the voiced phone [v]; to the voiced consonant [l] there corresponds a breathed sound represented in phonetic transcription by [l̥]. There is one consonant which is neither voiced nor breathed, namely the glottal stop (see below).

Consonant-phones are further classified according to the nature of the *gests* by which they are made. They are classified (1) according to their places of articulation; and (2) according to their manner of articulation. The following are some of the most important classes of consonants where classification is made according to place of articulation.

Bi-labial: articulated by the two lips. Examples [p, m], Japanese *f*.

Labio-dental: articulated by lower lip against upper teeth. Examples [f, v].

Dental: articulated by tip of tongue against upper front teeth. Examples: the English sounds of *th*, Spanish [t], Hindustani [t̪].

Alveolar: articulated by tip or blade of tongue against teeth-ridge. Examples: English [t, s].

Retroflex: articulated by tip of tongue against hard palate. Example: Hindustani [ɭ].

Palato-alveolar: articulated by blade of tongue against teeth-ridge, there being in addition a certain raising of the main body of the tongue towards the palate. Examples: the English sounds of *sh, ch*.

Palatal: articulated by 'front' of tongue against hard palate. Examples: English sound of *y* in *yet*, German *ch* in *ich* (one variety), Hungarian *gy* in *Magyar*.

Velar: articulated by 'back' of tongue against soft palate. Examples: [k], [g] as in *get*, *ng* as in *sung*, German *ch* in *Buch*.

Uvular: articulated by back of tongue against extremity of soft palate, with or without vibration of the uvula. Examples: Parisian [ʁ], Arabic [q].

Pharyngeal: made by contraction of the pharynx. Example: Arabic *ħ* [ħ].

Glottal: made by the vocal cords. Example: the glottal stop (the sound which replaces [t] in dialectal pronunciation of *little*).

The formation of dental, alveolar, retroflex, palato-alveolar, palatal, velar, and uvular consonants are illustrated in figs. 2-8.

Other types of consonant exist which are made in positions intermediate between those mentioned above. Thus the Spanish sound of *s* is not the same as the English but is intermediate between

this and the dental [θ¹]. The [s] in Sinhalese is somewhat similar. There exist also varieties of alveolar consonants made with the blade of the tongue against the teeth-ridge, the tongue-tip being kept down near the lower teeth. Most

French people use a [s] of this type; some English people (apparently about 25 per cent.) do the same. In Polish, sounds exist which may be described as alveolo-palatals; they have simultaneous palatal and alveolar articulation, the palatal element

Fig. 2.—Formation of a Dental Consonant (dental [t]).

Fig. 7.—Formation of a Velar Consonant [k].

preponderating; they are written *ś, ź, ċ* in Polish orthography. (The Pekingese sound commonly written *hs* is similar to the Polish sound of *ś*.) Other important sub-classes of consonants are 'palatalised,' 'velarised,' and 'pharyngalised' consonants. A palatalised consonant is one which has

its primary articulation further forward than the palatal position, but which has as a secondary articulation a raising of the front of the tongue towards the hard palate; the effect is to make the consonant reminiscent of the vowel [i]. Thus there exist labial palatalised consonants, labio-dental palatalised, dental palatalised, and alveolar palatalised

Fig. 8.—Formation of a Uvular Consonant (Arabic [q]).

consonants. Such consonants occur in Russian. A velarised consonant is one which has its primary articulation further forward than the palatal position, but which has as a secondary articulation a raising of the back of the tongue towards the soft palate; the effect is to make the consonant reminiscent of [u]. The [l] of *people* as pronounced in the South of England is an alveolar velarised consonant. Pharyngalised consonants have a constriction of the pharynx in addition to the primary articulation. The Arabic so-called 'emphatic' *f, ḡ, ẓ*, etc., are really pharyngalised *f, d, z*, etc.

¹ The English sound of *th* in *thin*.

The sounds last mentioned may be said to have double articulation. Many other consonants can be made with double articulation. Notable among them are plosive consonants with simultaneous or almost simultaneous glottal stop (phonetically, p' t', &c.), which occur in Zulu and numerous other languages of Africa, and the sounds known as 'clicks.'

The following are some of the most important classes of consonants when classification is made according to manner of articulation:

Plosive: air-passage completely closed for an appreciable time, then opened; the sudden escape of air produces a plosion (see below). Examples: [p, d].

Affricate: a kind of plosive in which the closure is released more slowly than in a normal plosive; the result is that the ear perceives the corresponding fricative while the articulating organs are being separated. Examples: the English sounds of *ch* in *church*, *j* in *jug*, the German sound of *z* (as in *zehn*), the Italian sounds of *z* (as in *zio, mezzo*).

Nasal: mouth passage closed, but soft palate lowered so that air escapes through the nose (as shown in fig. 9). Examples: the sounds of *m, n, ŋ* (as in *sing*).

Lateral: air passage obstructed in the centre of the mouth, but air issues on one or both sides of the obstruction. Example [l].

Fig. 9.—Formation of a Nasal Consonant (alveolar [n]). Compare alveolar [t] (Fig. 3).

Rolled (also called *trilled*): when a part of the organs of speech is so held that the air current causes it to vibrate rapidly. Example: rolled [r] as in some varieties of English, and in Italian; Spanish initial r (as in *re*) and rr as in *perro*.

Flapped: formed as rolled consonants, but consisting of one single tap. Examples: Spanish single [r] as in *pero*, Hindustani r, Hindustani r.

Fricative: air passage narrowed so that when the air-current passes, a frictional sound is heard. Examples [f, z, 's].

Semi-vowel: a gliding sound formed by putting the organs of speech in position for a vowel and immediately proceeding to another vowel-position without remaining any appreciable time in the first vowel position. Examples: y (as in *you*), w (as in *well*).

It will be observed that plosive consonants consist of two parts, viz. the part where there is complete closure during an appreciable time, and the part known as the *plosion*, which may be regarded for all practical purposes as instantaneous.

The first part is known as the *stop*. When the *stop* of a plosive consonant is very short, it is sometimes difficult to distinguish the sound from a flapped consonant. It is possible to make a stop without plosion, but it is not possible to make a plosion without a preceding stop. Stops without perceptible plosion are a characteristic feature of languages of the Chinese type. They also occur in other languages in groups of consonants; thus the [k] of the English word *act* is generally pronounced without plosion.

The Classification of Vowels.—It is convenient to use as the basis for the primary classification of vowels the position taken up by the tongue in forming them. The approximate limit of height of the tongue for the production of a vowel is shown approximately by the dotted line in fig. 10. If the tongue were nearer to the palate a fricative consonant would be produced. If the tongue is at or near this limit the vowel is called *close*; such

Fig. 10.—Formation of Vowels. Tongue must be below the dotted line.

Fig. 11.—Tongue-positions of Front Vowels.

Fig. 12.—Tongue-positions of Back Vowels.

are the English sounds of *ee* as in *see* and *oo* as in *moon*. If, on the other hand, the tongue is kept as low as possible in the mouth the vowel is called *open*; such is the sound of *a* in *father*. It is convenient to distinguish two intermediate degrees, *half close* and *half-open* (see figs. 11 and 12).

Vowels are also classified as *front* and *back* according as the raising of the tongue is in front (as shown in fig. 11) or at the back (as shown in

fig. 12). Examples of front vowels are the English vowels in *feet*, *get*, *cat*; examples of back vowels are the English sound of *aw*, the German vowels in *gut*, *wohl*. Vowels also differ from one another in lip-position as well as in tongue-position; with any given tongue-position the lips may be *spread*, *neutral*, *open-rounded* or *close-rounded* (figs. 13, 14, 15, 16) or in positions intermediate between these.

The Cardinal Vowels.—One of the objects of phonetics is to describe foreign vowels in such a way that people who have never heard them may form a good idea of what they sound like. To this end certain vowels have been selected, by reference to which any vowel may be described. These are eight in number² and are represented in phonetic transcription by the letters [i, e, æ, a, ɔ, o, u]. They have approximately the tongue positions shown in figs. 11 and 12. [i, e, æ, a, ɔ] have spread to neutral lips, [a] has open lip-rounding, [o] and [u] have close lip-rounding.

It will be seen from figs. 11 and 12 that the

¹ The English sound of *sh*.

² We describe here the system most generally adopted at the present time. Other systems have been devised, the most important of which is the *Bell-Sweet system*, which takes nine cardinal vowel positions as its basis.

tongue-positions of vowels may be conveniently shown by marking the highest point of the tongue on a diagram of the shape shown in fig. 17. The circumference of this figure represents approximately the limits of possible tongue-positions in every direction, so that the tongue-position of any vowel will be marked either on the circumference or in the interior of the figure. The tongue-positions of the cardinal vowels are indicated by dots on the circumference of the figure, as shown in fig. 18. The relations of other vowels to the cardinal vowels can be indicated by placing dots at the appropriate places on this diagram. Thus the tongue-position of a half-close vowel intermediate between front and back would be indicated by the dot lettered *e* in fig. 18, and so on. Vowels whose tongue-positions are intermediate between 'front' and 'back'

and which are not 'open' are called *central* vowels. Such are the English sounds of *a* in *about* and the Russian sound of *bl*. It is convenient to regard the 'central vowel' area as triangular in shape, as shown in fig. 18.

Fig. 17. - Diagram representing the limits of Tongue-positions for Vowels.

The cardinal vowels can only be learnt from a teacher who knows them, or failing that, with the aid of a gramophone record.¹ They cannot be learnt from written descriptions or by reference to the sounds of any language (owing to variations

Fig. 18.—Representation of Vowel Tongue-positions by Dots on this diagram.

in the pronunciation of different speakers). It is the vowels occurring in languages which have to be described by reference to the fixed cardinal scale.

A scale of eight secondary cardinal vowels is derived from the primary cardinal vowels by altering the lip rounding, viz. by adding lip-rounding to Nos. 1 to 5, and by unrounding Nos. 6, 7, and 8.

Students of languages who have mastered the cardinal vowels, and have acquired good control over the movements of the lips, will find the acquisition of foreign vowels relatively easy if they are provided with vowel diagrams of the type shown in fig. 19. For instance the numerous foreigners who have difficulty in distinguishing between the vowels in *man* and *men*, *cat* and *get*, &c., are greatly helped if they know that the vowel in *man*, *cat*, is about half-way between cardinal vowels 3 and 4, and that the vowel in *men*, *get*, is half-way between cardinal vowels 2 and 3.

Further information regarding the cardinal vowel system and its application may be found in *The Pronunciation of Russian* by Trofimov and Jones, chap. vi.

Phonemes.—It is important to distinguish between phones and certain families of phones existing in any given language and known as 'phonemes.' The nature of this grouping of the phones of a language is best shown by illustrations. It will be observed, for instance, that the *k*-sounds in *keep* and *cottage* are not identical, the [k] in *keep* being formed in a more forward position than that in *cottage*. Similarly the varieties of [k] used before other vowels are not all the same. Nevertheless, as the particular kind of [k] used in any particular case in English is determined by the nature of the adjoining vowel, it is convenient to regard this whole family of *k*'s as a single entity and call it the English *k*-phoneme. Again, in French when

Fig. 19. - Representation of Tongue-positions of the Vowels of various Languages.

a, English; b, French (excluding the nasal vowels); c, German; d, Italian; e, Spanish (principal members of the Phonemes); f, Russian (principal members of the Phonemes); g, Sinhalese; h, Siamana.

words like *people*, *uncle* occur finally, the sound of the *t* is voiceless [t̥]; but as this sound only occurs in this position and the ordinary [t] only occurs in other positions, the two sounds do not strike French people as being essentially different; they may be considered as members of the same phoneme in

French. This does not mean that they are necessarily members of the same phoneme in other languages; the Welsh sound of *ll*, for instance, is a variety of voiceless [t̥], but it does not belong to

¹ Record No. B 801, published by His Master's Voice Co., 863 Oxford Street, London, W.1.

the same phoneme as [l] in *Welsh*, because its occurrence is not dependent upon its situation in the word or sentence. Again, the Arabic [a] in *la* (no) is to an English ear quite different from those in *Allah*; to an Egyptian, however, the two sounds may be treated for grammatical and other practical purposes as a single entity; they are members of one phoneme, because the exact value of the [a] in every case depends on the nature of the surrounding consonants (for the rules see Gairdner's *Phonetics of Arabic*, published by the Clarendon Press, Oxford). It is *phonemes* which distinguish one word from another in spoken language; two *sounds* which are members of the same phoneme in a given language cannot distinguish one word from another in that language.

Theory of Phonetic Transcription.—Languages may be transcribed phonetically with any desired degree of exactitude. The simplest kind of transcription for a given language is one which provides one letter for each *phoneme* of that language. Such a system is called a 'broad' transcription; it is unambiguous, that is to say it distinguishes in writing all words which are distinguished in speech, and it indicates the correct pronunciation to all foreign readers who are familiar with the rules governing the use of the subsidiary members of the phonemes.

For some purposes, however—and especially in language teaching—it is useful to adopt a more detailed form of transcription. Such transcriptions are called 'narrow' transcriptions, and they provide not merely symbols for each phoneme of the language but also symbols for subsidiary members of

some of the phonemes. Thus in Gairdner's *Arabic Phonetics* a narrow transcription has been adopted in connexion with the a-phoneme, by introducing special symbols for two subsidiary members.

Systems of Phonetic Transcription.—There are three main types of phonetic transcription in existence: (1) alphabets of entirely new letters (such as the Bell-Sweet Organic Alphabet); (2) alphabets based on the Roman character supplemented by Roman letters with diacritical marks to denote sounds which cannot be represented by Roman letters (e.g. the Lepsius alphabet); (3) alphabets based on the Roman character with additional letters to denote sounds which cannot be represented by Roman letters (e.g. the alphabet of the International Phonetic Association). The third type of alphabet is the most satisfactory, in the opinion of the present writer. In such an alphabet it is not possible to dispense entirely with diacritical marks, but they are reserved as far as possible for representing length, stress, and pitch, and for the subsidiary members of phonemes. The essential feature of this type of alphabet is that every phoneme of a language should, as far as possible, have a letter of distinct design to represent it.

The following Table shows the International Phonetic signs for the speech sounds of the most important languages:

Phonetic Readers: It is only possible here to mention a few of the numerous phonetic readers; special attention may be called to the series published by the University of London Press (English, French, German, Italian, Welsh, Polish, Czech, Cantonese, Panjabi, Bengali, Burmese, Sechuana); many of these volumes contain outlines of the phonetic theory of the language dealt with. Other useful readers are: Passy, *Lectures Phonétiques Françaises*; Vietor, *Lehrbuch in Lautschrift*; Meyer, *Deutsche Gespräche*; Peers, *Spanish Phonetic Reader*; Gairdner, *Egyptian Colloquial Arabic*; Jones and Perera, *Colloquial Sinhalese Reader*.

Phonograph, an instrument for mechanically recording and reproducing articulate human speech, song, instrumental music, or other sound of which a record may be desired. The phonograph was invented by Mr T. A. Edison (q.v.) in the summer of 1877, at his Menlo Park Laboratory, New Jersey, the idea being evolved while studying certain phenomena in one of the many lines of experiment upon which he was engaged. Prior to 1877 Mr Edison had developed a successful system of automatic telegraphy; and in the summer of that year he was experimenting on an automatic method of recording telegraph messages on a disk of paper laid on a revolving platen, similar to the modern disk talking-machine. The platen had a spiral groove on its surface, like the disk. Over this was placed a circular disk of paper. An electromagnet with an embossing point connected to an arm travelled over the disk; and any signals (dots and dashes) given through the magnets were embossed on the disk of paper. Upon removing this disk and placing it on a similar machine provided with a contact lever, the latter was actuated by the embossed record so as to control the circuits and repeat the signals into another telegraph line. Mr Edison observed that if the disk was moved very rapidly the vibration of the lever resulted in the production of an audible note. From his experiments on the telephone he knew of the power of a diaphragm to take up sound vibrations, and indeed had made a toy with which this power was illustrated in a practical manner. In this toy a diaphragm was placed at the small end of a funnel, and to the diaphragm was connected a pawl, which engaging in a ratchet-wheel served to give continuous rotation to a pulley. The pulley was connected by a cord to a little paper toy representing a man sawing wood. If one recited loudly into the funnel, the vibrations of the diaphragm caused the pawl to operate the ratchet-wheel and rotate the pulley, when the paper man would start sawing wood. With all these facts before him Mr Edison reasoned that if he could record the movements of the diaphragm properly, he could cause such a record to reproduce the original movements imparted to the diaphragm by the voice, and could thus succeed in recording and reproducing the human voice. He therefore designed a machine for this purpose. Instead of using a disk at this time, his design provided for the employment of a cylinder with grooves around its surface. Around the periphery of the cylinder was to be placed a sheet of tinfoil, in which the movements of the diaphragm could be easily impressed by means of a tiny-pointed stylus attached to it. Mr Edison made a sketch of the machine, and gave it to one of his best workmen to be made up. Some of his men thought that the idea of recording and reproducing speech was absurd, and bets were made that the machine would not work. Mr Edison himself expected only that he might hear a word or so that would give hope for the future. When the machine was finished the tinfoil was put on, and he shouted into it, 'Mary had a little lamb,' &c., and upon adjusting the reproducer the machine reproduced it perfectly. This original model was loaned to the South Kensington Museum, London. In 1878 Mr Edison made a number of phonographs, which were exhibited in America and Europe, and attracted universal attention. The records in these machines were made of soft tinfoil sheets fastened around metal cylinders. In the autumn of 1878 Mr Edison commenced his investigations of the electric light problem, and was occupied for nearly ten years afterwards in completing and introducing his system. About 1887, however, he reverted to the phonograph, and worked it out to the practical commercial form in which it exists to-day. There was no change whatever in

the fundamental principles, but the mechanism was changed, and instead of employing tinfoil, a cylinder or disk of wax is used, the record being cut thereon by a sapphire cutting-tool attached to a diaphragm, while the reproduction is effected by means of a blunt diamond stylus similarly attached. The cutting-tool and stylus are minute devices, and they have to be cut, formed, and polished to an exact nicety by means of diamond dust, most of the work being performed under high-powered microscopes. The wavelike record cut into the wax by the cutting-tool being only about as deep as one-third the thickness of tissue-paper, some difficulty was experienced in keeping the reproducing stylus in perfect engagement with these minute waves. Mr Edison therefore introduced a 'floating weight,' which presses the stylus to its work; but because of its mass, it cannot respond to the extremely rapid vibrations of the stylus; they are therefore communicated to the diaphragm. Some of Edison's most ingenious inventions relate to the duplication of phonographic records. It is quite obvious that original records of celebrated musicians, singers, speakers, &c. could not be sold to the public, as in some instances a single record might cost hundreds of dollars. Hence means must be provided for making exact replicas in unlimited quantity. This has been the subject of much work and experiment. The methods now employed consist generally in putting the original wax cylinder or disk master record into a plating bath, where it is electroplated with a heavy coat of copper; after which the record is withdrawn, leaving an exact metallic negative of the original, from which any number of positive replicas can be made through a method employed by Mr Edison, involving the use of a hard material which is softened by heat and pressed into or upon the metallic negative. After the impression is made, the mould and contents are cooled and the duplicate record is drawn out.

The most extensive employment of the phonograph has been for amusement purposes. Its use for commercial correspondence has advanced to a very great extent, and its usefulness and economy as an office adjunct have been thoroughly demonstrated. For dictation purposes, blank wax cylinders are furnished, capable of receiving about 1500 words. After the dictation has been transcribed by the amanuensis, the record may be shaved off, leaving a new and smooth surface for fresh dictation. The cylinder may be used several hundred times.

Phonography. See SHORTHAND.

Phonolite. See CLINKSTONE.

Phormium. See FLAX (NEW ZEALAND).

Phoronis, a marine worm-like animal, living socially, each worm enclosed in a membranous or leathery tube. The Phoronidea, species of which are found off the New England coasts and in European and Australian waters, are by some associated with the Polyzoa (q.v.), but by some made a separate group.

Phosgene, a colourless suffocating gas, derived from carbonic oxide and chlorine exposed to the action of sunlight; it is also called carbonyl chloride and oxychloride of carbon (COCl_2).

Phosphates. See PHOSPHORUS, MANURE; also BONE, BONE-ASH, BONE MANURES.

Phosphatic Diathesis, in Medicine, designates the condition in which there is a tendency in the Urine (q.v.) to deposit white gravel.

Phosphorescence. Strictly speaking, the term is applied to the phenomenon, exhibited by certain bodies, of remaining luminous in the dark for some time after being exposed to a strong light. Certain preparations, such as calcium sulphide (see LUMINOUS PAINT), indurated limestone, &c.,

possess this property in a very high degree. With the great majority of phosphorescent bodies, however, the duration of the phenomenon is very short, rarely more than a small fraction of a second. Becquerel, who studied this phenomenon with great care, invented a very ingenious instrument for the purpose, called a *phosphoroscope*. The body to be tested is placed in a small drum, which has an opening at each end. In this drum there revolve two discs, mounted on the same axle, and pierced symmetrically with the same number of holes. They are so adjusted that when a hole in one disc is opposite to the hole in the corresponding end of the drum the second disc closes the hole at its end of the drum, and *vice versa*. Light is admitted by one of the holes in the drum so as to fall on the object, and it is examined through the other hole. It is obvious that, when the discs are made to revolve, the object is alternately exposed to light and presented to the eye. By a train of multiplying wheels, these alternations may be made to succeed each other as rapidly as the observer pleases, and thus the object is presented in the dark to his eye as soon after its exposure to light as may be desired. Almost all bodies are found to be phosphorescent; for instance, some kinds of pink rubies when exposed to sunshine in this apparatus appear to glow like live coals in the dark. When phosphorescence is continuous, bodies receiving light and giving off radiation of a lower refrangibility we have the phenomenon observed by Brewster and Herschel in quinine and certain crystals of fluor spar, and thence called *fluorescence*. The green colouring matter of leaves, a decoction of the bark of the horse-chestnut, and the common *canary glass* (coloured with oxide of uranium) are bodies which exhibit this phenomenon very well. Perhaps the most striking method of studying the phenomenon is to receive in a darkened room the solar spectrum (q.v.) on a sheet of white paper, and to pass over the coloured spaces a brush dipped in a solution of sulphate of quinine with sulphuric acid. No change is produced on the less refrangible rays, but in the blue and indigo spaces a strange change of colour is at once apparent where the liquid has been spread. This appears more strongly in the violet, and vividly in the spaces beyond the violet, where rays fall which excite no luminous sensation in the eye. By this experiment the visible length of the spectrum may easily be doubled. By using the electric light, which is peculiarly rich in these highly-refrangible rays, a prism of quartz, which allows them to pass very freely, and various fluorescent substances, Stokes has obtained spectra six or eight times as long as those otherwise visible. The characteristic of all these rays is that they are less refrangible than those from which they are produced. The entire phenomenon is, as Stokes first showed, identical in principle with Leslie's photometer, in which light was measured when changed into heat by absorption in the coloured glass, of which one of the bulbs of his differential thermometer was formed. Ordinary phosphorus (from which the phenomenon took its name) becomes luminous in the dark by slight friction; whence the common trick of drawing self-luminous figures on doors and walls with a stick of phosphorus, or an ordinary kiefner match wetted.

PHOSPHORESCENCE IN ORGANIC BEINGS.—The emission of light by minerals after insulation and the cognate phenomena of luminosity on heating, friction, cleavage, crystallisation, &c., are of quite different nature from the production of light by organisms, to which we now turn.

Luminosity due to Putrefaction or to Disease.—That many organic substances (especially fish) become luminous when decaying has long been known, and the explanation of this luminosity of

decay is now certain. It is due to several kinds of luminescent bacteria, such as may be seen, by their light, on herring and haddock hung up to dry.

Luminosity of Healthy Living Organisms.—(1) In the vegetable kingdom the instances of luminescence are few, and the majority of these are among algae and fungi. Most of the luminous fungi are Hymenomycetes (*Agaricus*, spp.): in some cases the mycelium (root-like threads) gives out the light; in others, as in *A. olearius*, not uncommon at the roots of olive-trees, it is the under surface of the mushroom-like head. The light is only seen while growth is progressing; it ceases so soon as the fungus is mature. Some grasses, a Euphorbia (*E. phosphorea*), a lily (*Lilium bulbiferum*), a poppy (*Papaver orientale*), and a nasturtium (*Tropaeolum majus*) have all been recorded as luminous. The last instance is worthy of note as having been observed by the daughter of Linnæus in 1762. It is probable, however, that there is no intrinsic luminescence in any flowering plants. The appearance may be due to luminescent bacteria or moulds. In the so-called 'luminous moss' (*Sclerostegia osmundacea*), which lives in caves, lens-like cells in the threadwork (or protonema) focus the scanty rays of light and then reflect them. But this is just like the cat's or sheep's eyes shining in the dark. There is no light-production in these cases.

(2) In the animal world most of the larger groups, up to and including the fishes, afford examples of luminescence. Among the Protozoa the pinhead-like *Noctiluca miliaris* is the chief cause of the 'phosphorescence' of the sea. On the high seas *Noctiluca* seems to be replaced by species of *Pyrocystis*, one of the discoveries of the *Challenger* expedition. Among the Porifera (sponges) the only recorded luminous form is the larva of a species of Reniera. In contrast to the dullness of sponges is the abundant luminosity of the Ctenophora. The common hydroid colony *Obelia geniculata* shines in the dark on the fronds of the sea-tangle. Numerous Medusæ (jelly-fishes) are luminous, and the light is variously emitted in different species. Sometimes the same genus includes both luminous and non-luminous forms. Most Pennatulids (sea-pens) shine brightly; such are the long, reed-like *Eumecilia* found in Loch Torridon (Ross-shire) and on other parts of the Scottish coast, and Pennatula, the subject of classic researches by Panceri. Alcyonarians, Siphonophores, and Ctenophores also furnish contributions to the list; amongst the last the small ovoid *Beroë* was shown by Allman not to give out its light until it had remained for some time in the dark.

A few species of Ophiurids (brittle-stars) and the deep-sea asteroid *Odinia* are instances of luminosity among the Echinoderms, but the worms furnish a larger array. More than one case has been noticed among earthworms; thus in Photodrilus, studied by Professor Giard, the luminous material is due to a series of glands opening into the oesophagus. In these forms the luminosity ceases immediately after sexual congress. Among the marine Chaetopods there is luminescence in many cases—in the dorsal scales (elytra) of the Polynoidæ, the tentacles, dorsal tubercles, &c., of Chaetopterns, and the bunch of cephalic tentacles of Polycirrus.

Of phosphorescent mollusca the small pelagic *Phylliroe bucephala* is of importance, because the transparency of its tissues permits of the localisation of its luminosity, which is found to reside around the nerve ganglia, as well as in certain small rounded cells situated at the ends of the nerve twigs. The rock-boring bivalve (*Pholas*) one of the long known instances of animal

phosphorescence, being recorded by Pliny, who noticed that if any one chews the animal the whole interior of his mouth becomes luminous. In this form the light is emitted from five definite patches all situated within the mantle cavity.

Interesting observations upon bacteria as the cause of phosphorescence have also been made on Crustacea of the genera *Talitrus* and *Orchestia* (sand-hoppers) in a state of disease; the malady, and the consequent luminosity, can be transferred to healthy specimens by inoculation, and the germs can be reared in artificial media in the usual manner. It seems that the sand-hoppers are infected from dead fish, on which they habitually feed. Many other Crustacea, however, are luminous apart from any question of disease, as in Cypripodina and Supphirina, and still more markedly in the Schizopoda, one of which, *Nyctiphanes norvegica*, is not uncommon in the deep waters of Loch Fyne as well as on the Norwegian coast. Definite organs (photosphæria) are here present for the production of light; one in the stalk of each eye, one at the root of each first, and one at the root of each penultimate, thoracic limb, and one under each of the first four segments of the abdomen. Each organ, as has been proved by microscopic sections, is in reality a miniature bull's-eye lantern, only equalled in complexity by the organs of certain fishes. Several phosphorescent Ascidians are known, the most conspicuous being the pelagic colony *Pyrosoma*, in which each individual zooid has two rounded luminous organs. The researches of the various deep-sea expeditions have revealed quite a large number of phosphorescent fishes, with specialised organs of many different types. Some of these appear to be glandular, whilst others are optical instruments of great complexity, with spheroidal and parabolic reflectors to send the light in definite directions and with lenses to concentrate it. In some of the abyssal Lophioids (angler fish) the modified dorsal fin-ray, believed to be a lure, has a phosphorescent extremity, which may render it more attractive.

In two East Indian fishes (*Anomalops* and *Photichthys*) the luminous organs are very large and give out light continuously, while in other cases the luminescence follows some stimulus. Newton Harvey's investigations point to the conclusion that the light-organs of these two fishes are incubators for the growth and nourishment of luminous bacteria living in symbiosis. When animal luminescence is intrinsic and due to some ferment-like action, not to bacteria, the oxidisable material may be oxidised within the cells where it is formed, as in deep-sea fishes, or it may be secreted to the exterior and oxidised outside the cell. Of the latter a fine instance has been discovered by C. F. Hickling in a Maenid fish, *Malacocephalus laevis*, which lives in deep water from Ireland south to Morocco. By muscular contraction it puffs out a secretion from a skin-gland between and behind the pelvic fins. This secretion is oxidised in the water and gives forth 'a cloud of light.'

There still remain for consideration the phosphorescent insects, which belong almost exclusively to the Coleoptera (beetles) in the families Lampyridæ and Elateridæ. The glow-worm (*Lampyrus splendidus*) and the Italian firefly (*Luciola italica*) are good examples of the former. In both cases the organs, which are situated in a certain number of the posterior segments of the abdomen, consist of two layers, of which the dorsal contains large quantities of uric acid salts, and the ventral clear cells, which are arranged in cylindrical lobules. In some species both sexes are luminous, in others only one. In the Mexican firefly or Cucuyo (*Pyrophorus noctiluca*), which belongs to the Elateridæ or click-beetles, the organs are three in number,

one in each upper and hinder angle of the prothorax, and one much larger occupying the centre of the ventral surface of the first abdominal segment. This last is invisible while the insect is at rest, but shines forth when it spreads its wings and raises its abdomen in flight. Both the eggs and larvæ of this species are luminous. The so-called Lantern-flies (Pulgoridæ) in the order Hemiptera are not really luminous.

As regards the physical peculiarities of the light, it varies in colour in different cases, being blue in the mycelium growing in rotten wood, in *Cinina*, *Beroë*, *Pyrosoma*, and *Lampyrus*; green in a species of *Agaric*, in *Pteroides*, in *Ophiuroids*, and in *Pyrophorus*; yellow in *Noctiluca*, *Bolina*, and with a reddish tinge in a species of *Cestum*; purple in *Fuiculinia* and others; whilst in *Pyrosoma atlanticum* and an *Appendicularia* observed by Giglioli it has been stated that the light varies in colour. The important general fact is that the animal light is all visible light, with no infra-red or ultra-violet rays, and that there is no heat associated with it.

As regards the production of the light, it may be said that just as muscle cells produce heat and the electric organs of some fishes produce electricity, so certain cells of luminous organisms produce light *in situ* or exude material that is luminescent. In the firefly, the small crustacean Cypripoda, and the piddock, it seems practically certain that a protein-ferment called luciferase acts on a light-producing peptone-like substance called luciferin, and brings about a rapid oxidation resulting in oxy-luciferin and light. In some other cases, however—e.g. some fishes, fire-flames, and cuttlefishes—the evidence points to the conclusion that the light comes from groups of partner or symbiotic bacteria. Yet it has not been shown that these are luminescent when isolated.

As to the significance of animal luminescence, it may sometimes be no more than the by-play of some physiologically important chemical change. If the contraction of a muscle is associated with an electrical change, so may the life of a bacterium or a firefly's egg be associated with the production of light. It is not necessary to search for any special use. But the problem is different when there is an elaborate luminous organ or a definite arrangement of organs. In such cases there must be some use or uses. There are various possibilities. (1) The light may serve to scare, distract, or warn intruders, e.g. from a big Sea-pen. (2) The light may be a lure, attracting victims, as in the Deep-sea Anglers (e.g. *Melanocetus*), where the luminous organ dangles near the mouth. (3) The light may serve as a lantern, helping animals, e.g. abyssal squids and fishes, to find their way. But the hypothetical guide is sometimes in a very inappropriate place for food-capturing purposes. (4) The light may facilitate the recognition of kin by kin, and may serve as a sex-signal in mating. This fits in with what is known of fireflies; and it is noteworthy that the toad-fish, *Porichthys*, to take one example, is luminous only during the spawning-season. There is obviously great need for more facts. See FIREFLY, GLOW-WORM, and works there cited; and Kayser's *Handbuch der Spectroscopie* (iv. 1908); E. Newton Harvey, *The Nature of Animal Light* (1920); P. Buchner's *Tier und Pflanze in intrazellulärer Symbiose* (1921).

Phosphorus (syn. P; atom. no. 15; atom. wt. 31; molec. wt., vapour, $P_4=124$; at white heat, $P_2=62$) is one of the metalloids or non-metallic elements, although in its combining relations it is closely connected with the metals arsenic and antimony. This substance affords an excellent example of Allotropy (q.v.). Ordinary phosphorus and the red variety are the only impor-

tant forms. We shall speak of them as phosphorus and red phosphorus respectively.

Phosphorus at ordinary temperatures is an almost colourless or faintly yellow solid substance of sp. gr. 1.836, having the glistening appearance and the consistence of wax, and evolving a disagreeable alliaceous odour, which, however, is probably due to the action of the oxygen of the air upon it. It fuses at 44.2°C . (111.5°F .) into a colourless fluid; and, if the air be excluded, it boils at 290°C . (554°F .), and is converted into a colourless vapour of sp. gr. 4.35 (air = 1.00). If, however, it be heated to about 60°C . (140°F .) in the air it catches fire, burns with a brilliant white flame, and is converted into phosphoric anhydride; and indeed it is so inflammable that it will catch fire at ordinary temperatures by mere friction. As the burns which it occasions are often severe and dangerous, great caution is required in handling it; and in consequence of the readiness with which it catches fire, and of its tendency to oxidise when exposed to the air at a temperature higher than 0°C . (32°F .), it is always kept in water, in which it is insoluble. It is slightly soluble in ether, but dissolves freely in benzol, in the fixed and essential oils, and in bisulphide of carbon; and, on allowing its solution in a volatile solvent to fall upon filtering paper, the finely-divided phosphorus absorbs oxygen so rapidly as spontaneously to catch fire as soon as the solvent has evaporated. Phosphorus shines in the dark from the slow combustion which it undergoes; and hence its name, from the Greek words *phos*, 'light,' and *phoros*, 'bearing.' Its power of forming ozone is noticed in the article on that substance. Taken internally, phosphorus is a very powerful irritant poison; and it is the active ingredient of some of the preparations employed for the destruction of vermin. Its fumes give rise to a peculiar form of necrosis of the jaw and to fatty degeneration of the kidney, which used to be common amongst the makers of lucifer matches.

Red phosphorus is prepared from the ordinary variety by heating the latter in a closed iron vessel to a temperature of 240°C . (464°F .). It was discovered

by Schröter in 1845, and is a compact solid substance of a dark red colour, and with a metallic lustre. It differs much in its properties from common phosphorus, being devoid of odour, does not shine in the dark, undergoes no change when exposed to the air even for years, and cannot be set on fire by moderate friction or percussion. Moreover, it is insoluble in all the solvents of common phosphorus, and is not poisonous. It bears heating to nearly 260°C . (500°F .) without taking fire, and has a specific gravity of 2.16. By using red instead of white phosphorus for lucifer matches there is no risk to the health of the operatives. Safety matches contain chlorate of potash and ignite on a surface containing a mixture of red phosphorus and sulphide of antimony (see MATCHES).

Phosphorus is not met with in nature in an uncombined state; but it occurs in rocks of various kinds and ages, and in some countries abundantly as apatite or phosphorite, both of which are composed of phosphate of lime. It is also found in the form of Coprolites (q.v.), or the dung of extinct animals, and more rarely as wavellite (phosphate of alumina) and vivianite (phosphate of iron). In many volcanic rocks apatite is found in minute crystals or particles, and by the decomposition of these rocks it passes into the soil. From the soil it is extracted by plants, which accumulate it (especially in the seeds of the cereals) in quantity sufficient for the wants of the animals which they supply with food. In the animal system phosphate of lime forms 57 per cent. of the bones; phosphates of the alkalies, especially of soda, occur freely in

the animal fluids; and in fibrine, albumen, and nervous matter phosphorus is universally present, although we do not clearly know in what form of combination it occurs.

Phosphorus was originally discovered in 1669 by Brandt, a Hamburg chemist, who obtained it from urine. Gahn and Scheele were, however, the first to discover its presence in bone, and to employ that material for its preparation. The following was the method employed for obtaining it on the large scale. Bones were burned to whiteness, and powdered; and this bone-ash then mixed with sulphuric acid in such quantity as to decompose the phosphate of lime occurring in the ash, partly into a soluble superphosphate of lime, whose composition is represented by the formula $\text{Ca}(\text{PO}_4)_2$. The solution of the superphosphate was evaporated to a syrup, mixed with charcoal, and submitted to distillation in an earthen retort exposed to a red heat. Phosphorus rose in vapour, and was conveyed by means of a bent tube into water, in which it condensed in yellow drops. It is now prepared by heating in an electric furnace a mixture of calcium phosphate, sand, and coke. After being pressed in a fused state through wash-leather, and further purified, it is forced into tubes, in which it is allowed to solidify, giving it the usual form of sticks. Sombrierite (see APATITE) is largely used in the manufacture of phosphorus.

Phosphorus forms two known oxides—phosphorous anhydride, P_2O_3 , obtained by the slow oxidation of phosphorus in dry air; phosphoric anhydride, P_2O_5 , obtained by the combustion of phosphorus in an excess of dry air or oxygen. The latter is a snow-like substance which has a great avidity for water, and is therefore very useful in the laboratory as a desiccating agent.

Phosphorus forms five acids—hypophosphorous acid, $\text{H}_2\text{P}_2\text{O}_4$, monobasic (the anhydride, P_2O_4 , is not known); phosphorous acid, $\text{H}_2\text{P}_2\text{O}_3$ ($= \text{P}_2\text{O}_3 + 3\text{H}_2\text{O}$), dibasic, obtained by slow oxidation of phosphorus in moist air or by passing chlorine gas through phosphorus under hot water; metaphosphoric acid, HPO_3 ($= \text{P}_2\text{O}_5 + \text{H}_2\text{O}$), monobasic, obtained by dissolving P_2O_5 in water or by heating ordinary phosphoric acid to redness; pyrophosphoric acid, $\text{H}_4\text{P}_2\text{O}_7$ ($= \text{P}_2\text{O}_5 + 2\text{H}_2\text{O}$), tetrabasic, obtained by acting upon lead pyrophosphate with sulphuretted hydrogen, the lead salt being prepared from soda pyrophosphate, which is obtained by heating such a phosphate as $\text{Na}_2\text{H}_2\text{P}_2\text{O}_7$, of which two molecules give off one of water and form $\text{Na}_4\text{P}_2\text{O}_7$; phosphoric or orthophosphoric acid, H_3PO_4 , tribasic, prepared by boiling P_2O_5 in water, or from bone-ash and sulphuric acid; the last-named acid has three sets of salts, the hydrogen in the acid being more or less completely replaced—e.g. NaH_2PO_4 , Na_2HPO_4 , and Na_3PO_4 , which are obtained by more or less completely neutralising phosphoric acid with soda.

The discovery of phosphoric acid was made in 1749 by Marggraf; the discovery of its true chemical nature is, however, due to Lavoisier, and that of its various modifications and its participation in the investigations of Graham. The salts of phosphoric acid are phosphates; and they are of great value, when in a soluble form or when they can become soluble through weathering, as manures (see MANURE). Of late years mineral phosphates have been largely worked up; and a new source of phosphatic manure has become available in the alkaline slag of the Thomas-Gilchrist process, whereby the phosphorus is removed from iron by means of lime.

Phosphorus combines with hydrogen in three proportions to form phosphuretted hydrogen gas,

PH_3 ; liquid phosphide of hydrogen, P_2H_4 ; and solid phosphide of hydrogen, P_3H_2 . Of these the first alone requires notice in these pages. There are various processes for obtaining the gas, one of the simplest being by boiling fragments of phosphorus in a concentrated solution of hydrated potash, in which case hypophosphite of potash is formed, while phosphuretted hydrogen gas is extricated. The reaction is explained by the equation $4\text{P} + 3\text{KHO} + 3\text{H}_2\text{O} = 3\text{KPO}_2 + \text{PH}_3$. The gas thus evolved is colourless, possesses a characteristic fetid odour, and has the remarkable property of taking fire spontaneously in atmospheric air or in oxygen gas, with the production of anhydrous metaphosphoric acid and water. There is reason to believe that perfectly pure phosphuretted hydrogen gas does not possess the power of igniting spontaneously, and that the self-lighting gas always contains a minute quantity of the vapour of the liquid phosphide, P_2H_4 . The luminous phenomenon known as Ignis Fatuus (q.v.) has been referred to the natural evolution of the gas. The compounds of phosphorus with chlorine, iodine, bromine, &c. are not of practical importance. With sulphur it forms a sulphide used for making matches since the use of yellow phosphorus has been forbidden.

The symptoms of phosphorus poisoning are those of acute inflammation of the stomach and bowels; the treatment is the administration of large quantities of mild demulcent fluids, and of magnesia. For medicinal phosphates, see SYRUP.

Photius, Patriarch of Constantinople at a critical period, was a member of a patrician family of Constantinople, and was born in the early part of the 9th century. Distinguished by his abilities, he served in various important public offices, and secured the favour of the Emperor Michael and his powerful favourite Bardas. The patriarch Ignatius, having in vain tried to correct the vices of the profligate emperor, was deposed and banished. Photius, although a layman, was appointed in his stead, hurried in a few successive days through all the stages of sacred orders, and finally installed as patriarch. Two successive councils of bishops under court influence confirmed the deposition of Ignatius and the election of Photius. In 862, however, Pope Nicholas I. (q.v.) called a new council at Rome, which declared Photius' election uncanonical and invalid, deposed and excommunicated him, and reinstated Ignatius in his see. Being supported, however, by the emperor, Photius retained possession, and retaliated on the pope by assembling a council at Constantinople in 867, in which he raised a controversy of doctrine and discipline between the churches of the East and West themselves. In all these doctrinal differences the council condemned the Western Church, excommunicated Nicholas and his abettors, and withdrew from the communion of the see of Rome. Michael being put to death by Basilus the Macedonian in 867, Photius was banished to Cyprus, and Ignatius reinstated; and in 869 the eighth general council, at which Pope Adrian II.'s legates presided, was assembled at Constantinople. Photius was again condemned and excommunicated, and the intercommunion of the churches restored. Yet on the death of Ignatius Photius was reappointed to the patriarchate. In 879 he assembled a new council at Constantinople, renewed the charge against the Western Church, and erased from the creed in the article on the Procession of the Holy Ghost the word *filius* (see SPIRIT). The separation of the churches, however, was not completed till the time of Michael Cerularius (see GREEK CHURCH). Photius was finally deprived, and exiled to Armenia by Leo, the son of Basilus, in 886, and

died soon afterwards, probably in 891. His chief remains are *Myriobiblon*, called also *Bibliotheca*, a summary review of 279 works which Photius had read, many of which are now lost; a *Lexicon*; the *Nomocanon*, which is a collection of the acts and decrees of the councils and ecclesiastical laws of the emperors; several minor theological treatises; and a collection of letters, interesting and elegant. See Hergenröther's monograph on Photius (1869), and Kattenbusch in Herzog-Hauck (1904).

Photography. Observation shows that a large number of substances which are permanent in the dark become altered when exposed to light. The extent of such changes, though varying for different substances, is proportionate in any particular instance to the amount of light energy the body receives (except in certain exothermal reactions, as with a mixture of hydrogen and chlorine, for example, when the change leading to combination is only initiated by light); in other words, the affectability varies for each material—a fact of everyday experience. In some cases the change is physical; as, for instance, the alteration in phosphorus. More frequently, however, the composition of the substance is changed, and such change is termed photo-chemical. It is upon these changes that the art of photography is based, and a photograph is the pictorial representation of an object produced by the action of light. To-day all changes in bodies produced by the agency of light are in chemical literature classified as photo-chemical changes, but very many of these are not serviceable for the purposes of photography, which confines itself almost entirely for material to the compounds of silver, iron, and chromium.

The fact that native chloride of silver (*cerargyrite*), the so-called horn silver, became darkened on exposure to daylight was known to Boyle (and probably to the alchemists in earlier times), though he considered the changes to be an effect of the air. In 1727 J. H. Schulze found that a mixture produced by the addition of nitric acid containing silver to chalk darkened upon exposure to light—the earliest recorded experimental observation. J. B. Beccari of Bologna showed in 1757 that the change in appearance following the exposure of silver chloride was an effect of light, and in 1763 Dr William Lewis confirmed Schulze's experiments. In 1777 C. W. Scheele confirmed Beccari's observation upon silver chloride showing that the change was due to light action; and, further, discovered the important fact that when this body was exposed to the spectrum the darkening was not proportional to the luminosities of the different regions, but that the violet was the most active influence. These experiments of Scheele's may be said to mark the commencement of the serious study of photo-chemical change. In 1801 Ritter showed that there existed a region beyond the visible violet capable of exerting an influence on silver chloride. The first utilisation of the facts observed for the production of pictures was made by Thomas Wedgwood, who in 1802, in conjunction with Davy, communicated to the Royal Institution a paper entitled 'An Account of a Method of copying Paintings on Glass and of making Profiles by the Agency of Light upon Silver Nitrate.' This paper has often been misunderstood, for it has been thought that the pictures the author produced were themselves upon glass—a condition only reached after many years' labour. It was the original pictures used that were upon glass. Wedgwood related how white leather and white paper which had been impregnated with silver nitrate darkened when exposed to light, though undergoing no changes in the dark, and the colour, at first gray, became ultimately black. It was found not possible to fix the effect, for even prolonged washing did not appear to elimi-

nate the silver salt, so that the picture darkened eventually on exposure.

No further advance appears to have been made until 1827, when Joseph Nicéphore de Niepce (q.v.) announced the production of pictures by the action of light upon asphalt. He showed that when a film of this body (produced by coating a silver plate with a solution of the body in oil of lavender) was exposed to light the asphalt became insoluble. Similar experiments appear to have been conducted by the French scene-painter and panorama proprietor, Daguerrre, who in 1829 entered into a partnership with Niepce, and the two workers conducted many investigations. Niepce died in 1833 and on 6th February 1839 Daguerrre published his process, which consisted in subjecting a polished silver plate to the vapour of iodine, when it became coated with a film of silver iodide. This plate was then exposed to an image in the camera obscura, with the result that the iodide of silver became changed, but there was no visible effect. It was subsequently treated to the vapour of mercury. The mercury vapour attached itself to the exposed portions of the silver iodide, forming an amalgam. The plate was then dipped into a solution of sodium thiosulphate, with which the iodide of silver formed a soluble double salt, afterwards removed by gently washing in water. The plate on drying presented an image in white amalgam upon a silver ground. The treatment by mercury vapour (discovered by pure accident) was the first process of development of an invisible photographic image. The exposure necessary in the camera was very prolonged, varying from three minutes to thirty minutes. In 1840 Goddard published the use of bromine vapour after iodine, and in 1841 Claudet used iodine and chlorine, which greatly enhanced the sensitiveness of the plates. It was in 1840 that the first photographic picture of the moon was made. This was produced on a daguerreotype plate by Dr J. W. Draper in New York. In 1844 Daguerrre himself announced an improved method involving the use of bromine and iodine. So much was the sensitiveness increased that it was found possible to obtain instantaneous pictures.

At the Royal Institution on 25th January 1839 Faraday described a process due to Fox Talbot (who made a similar communication to the Royal Society on 31st January)

in, in which a sheet of paper was impregnated with silver chloride and then exposed to light under an opaque or semi-transparent object (as a fern leaf), a negative copy was produced. The image was fixed by immersion of the sheet in a solution of alkaline bromide and chloride.

In 1841 Fox Talbot patented a process termed 'calotype,' which was the first practical process for making negatives. In this method a sheet of paper is impregnated with silver iodide, which is, previous to exposure in the camera, wetted with an aqueous solution of silver nitrate and gallic acid. After exposure (when generally a faint image may be seen) the sheet is treated with a stronger solution of gallic acid and silver nitrate, which acts as a developer and produces an intense image of black silver. The negative is then immersed in a solution of sodium thiosulphate, and finally washed and then dried. By this discovery practical photography as we understand it may be said to have commenced, as the process was a true negative process from which positive copies could be produced. Strictly speaking, the calotype process was not due to Fox Talbot alone, but in no small degree to the Rev. J. B. Reade, to whom belongs the credit of the development by the gallic acid.

The next advance was the albumen process of Niepce de St Victor, a nephew of Nicéphore, which was introduced on 13th June 1848. Glass was

coated with white of egg and potassium iodide, and the surface dried. After this the film thus obtained was treated with silver nitrate, and then exposed either wet or dry in the camera, and eventually developed with gallic acid. For the first time we have a vehicle employed for the silver salt—the albumen—as distinct from the support, glass.

In 1846 Schönbein announced the discovery of the method of nitrating cellulose. One form of nitro-cellulose is (gun-cotton (q.v.); but a mixture of the tetra- and penta nitrates yields pyroxyline, which is soluble to a clear liquid in a mixture of ethyl ether and ethyl alcohol, yielding Collodion (q.v.), first prepared by Maynard of Boston in 1847. Its application to photography was possibly first suggested by Le Grey, but its practical employment was due to the labours of F. Scott Archer in England, who used it for negative-making as early as 1848, though his process was first published in 1851. In the collodion process glass is coated with collodion containing a soluble iodide or an iodide and a bromide. When the solvents evaporate there is left only a jelly-like film, and at this stage the plate is immersed in a solution of silver nitrate, when insoluble silver halide (or a mixture of halides) is formed, which remains imbedded in the film. The plate is exposed in the camera wet, and afterwards the invisible image developed with an acidified solution of ferrous sulphate (although an acidified solution of pyrogallol was originally used), and the plate treated with sodium thiosulphate and washed. The use of pyrogallol as a developer was first suggested by Scott Archer. In *La Lumière* for the 23rd April 1853 Martin and Jandin recommended potassium cyanide as a fixing agent for the plates, and this is now universally used for the purpose. From this time onward photography became increasingly used and its popularity extended, but inconvenience attached to the necessity of using the plates in a wet condition and at the time of sensitising. This induced Gandin in France and Muirhead in England in 1854 to experiment with the object of providing satisfactory dry-collodion plates. The first practical method was published in 1855 by Dr J. M. Tanpenot, which consisted in washing the collodion plates after sensitising, and then flowing over the surface a solution of albumen of eggs, and drying afterwards. The dried film was then treated with silver nitrate solution containing acetic acid, washed, and dried. The plates would, thus prepared, keep several days. After exposure the image was developed with an acidified solution of pyrogallol to which silver nitrate had been added. Many dry-plate processes 'with the bath,' as they were termed, came into regular use, one of the most successful being the 'gun gallic,' due to Manners Gordon.

In 1862 Major Russell introduced the alkaline developer (although it is doubtful whether he was the first user) for the development of images. This consisted of a solution of pyrogallol and ammonia together with a restrainer, potassium bromide. In 1864 a great advance was made by Sayce and Bolton in England, who produced a collodion emulsion containing silver salts, although the emulsification of silver salts for photographic purposes had previously been tried by others. In Sayce and Bolton's process the soluble halide (a bromide) was dissolved in collodion, and to it was added an alcoholic solution of silver nitrate, when a fine precipitate of silver halide was formed, which remained in suspension. This emulsion was applied to glass, and the film so produced was then washed (to free it from the soluble products of decomposition) and exposed in the camera or exposed after previous drying. The image was subsequently developed by the alkaline developer.

This process, not entirely encouraging at first, became eventually of importance, and was the forerunner of the gelatine emulsion process. When Russell introduced the alkaline developer a dilute solution was recommended; but in 1873 Colonel Stuart Wortley advised a more concentrated solution—a very important step, inasmuch as it permitted of a reduction in the exposure. Where previously the procedure had been to use a weak developer it was quite necessary to give relatively long exposures; but with the Wortley system the camera exposure was reduced, and the effect of light was completed by the use of a powerful reducing agent. This apparently simple thing was in reality important, for it represents even to-day partially the means by which short exposures in the camera can be utilised for negative-making.

The inception of the gelatine-bromide dry-plate process, in which a halide of silver is emulsified in gelatine and applied to glass—the modern sensitive surface—was due to Dr R. L. Maddox, who in 1871 produced the first gelatine emulsion, by means of the addition of a solution of silver nitrate to a solution of gelatine containing cadmium bromide, the emulsion so prepared being applied to glass and paper. In 1873 an emulsion was placed on the market by Burgess, which, however, did not keep. In the same year Kennett produced a practicable article, but the difficulties connected with its use induced Kennett to turn his attention to the manufacture of plates, and the first batch was issued in 1874. Still it was not until 1880 that dry plates came into general use. Gelatine emulsion was applied to paper for the production of positive prints by development, and the first commercial bromide-paper was announced by Peter Mawdsley, of the Liverpool Dry Plate Company, Clapham Junction, in 1874.

So far pyrogallol had been the reducing agent in the developers used. In 1877 ferrous oxalate in a solution of potassium oxalate was introduced independently by Carey Lea and by Wills, and in 1880 an alkaline solution of hydroquinone (quinol) by Eder and Toth. The form of the developer used has always had an important bearing upon negative production, and since the introduction of hydroquinone many agents—generally benzene and naphthalene derivatives—have been added to the list. The improvement in the sensitiveness of dry plates which has taken place since their introduction by Kennett, and in the other qualities necessary, is matter of common knowledge, and their manufacture is now an extremely important branch of chemical industry. Probably the greatest triumph, so far as any single quality is concerned, is the enhancement of their spectral sensitiveness. As far back as the days of Scheele the fact was known that a silver salt, though sensitive to light, possessed a selective sensitiveness to colours, and that the effect was not in correct proportion to the order of their luminosity. In 1874 Dr H. W. Vogel of Berlin showed that by treatment of the film with certain easily oxidisable coal-tar colours (corallin, eosin, Magdala red) an increase in the sensitiveness for certain spectral regions took place. Eosin was applied to the sensitising of gelatine dry-plates on a commercial scale by B. J. Edwards in 1886, and such plates became known as isochromatic or ortho-chromatic, in spite of their insensitiveness to red and orange. The increased sensitiveness to green and yellow gives a much better rendering in landscape work, but for the satisfactory recording of reds continued efforts had to be made till the introduction by Miethe of isocyanin dyes, and later of carbocyanins by König, provided plates sensitive not only to red but even the infra-red region of the spectrum. Plates which are sensitive to the whole of the

visible spectrum are termed panchromatic, but the sensitiveness to the various wave-lengths is not equal, nor is it proportionate to the visual luminosity. In the panchromatic plate, as in the eosin sensitised ortho-chromatic plate, the inherent sensitiveness of the silver bromide to blue and violet preponderates over the effect of the dye, and in order to reduce the action of the more refrangible rays a correction filter or 'yellow screen' must be used on the lens. The absorption of such a filter is adjusted to the sensitiveness of the plate and the result required. With the modern panchromatic plate the colour of the filter adjusted to render colours in proportion to their visual luminosities is greenish-yellow.

The recent discovery that certain dyes destroy the light-sensitiveness of exposed plates without destroying the latent image allows development to be watched under white light of low intensity. Phenosafranine was the dye first introduced by Dr Luppé Cramer, but has been largely superseded by pimaricryptol green. The advantages of desensitising are obvious in the case of panchromatic plates which normally must be developed in total darkness. The exposed plates are bathed in a very dilute solution of the desensitiser before development, or desensitiser may be added to the developer.

In recent years much research work has been done on the theory of photography, and the application of modern developments in physics and chemistry, particularly colloidal chemistry, has proved very fruitful, though few general conclusions can be made as yet.

Film Photography.—Without doubt glass is the most convenient and satisfactory support for the sensitive surface, but its weight and the possibility of breakage are objections. When extreme portability in cameras became the aim of apparatus-makers, endeavours were made to find a suitable material to replace glass; many substances were tried, and eventually celluloid was adopted. In 1888 Carbutt of Philadelphia introduced sensitive coated celluloid film, followed by the Eastman Company in 1889, who in 1903 sent out 'non-curling' film—the curling tendency being overcome by coating the plain side with gelatine. Films in the form of flat sheets are used in place of glass plates or in a special form of packing called a 'film pack,' which enables each film to be brought to the front after the preceding one has been exposed. 'Rollable film' is wound on spools together with a longer strip of black paper so arranged that the spool can be inserted and removed in daylight. This method of winding the spools also makes it possible to wind the exposed film into a special tank so that it can be developed and fixed without the aid of a dark room. The Eastman 'Kodak' cameras have made rollable film the most popular type of sensitive material for the amateur, and it lends itself to development and fixing with the minimum of handling.

Rollable celluloid film is used in enormous quantities for both the negative and positive films used in the Kinematograph (q.v.).

Printing Processes.—In photography the term 'printing process' is applied to those methods by which positive copies are produced from negatives. The process described by Fox Talbot at the Royal Institution, by which paper impregnated with silver chloride was exposed to light under an opaque or translucent flat object, was the earliest printing method introduced. The pictures after fixation were always weak in intensity and poor in colour, especially after the use of sodium thiosulphate, which attacked vigorously the darkened silver salts. To avoid these defects excessive printing was adopted, and the prints were immersed in

a solution of acidified chloride of gold (introduced first by Le Grey), and afterwards fixed. To check the excessive loss an alkaline solution of gold chloride was next tried, and this eventually became the method of toning. To impart a gloss to the surface of the paper the salt solution originally used was replaced by salt (or ammonium chloride) and albumen of eggs (introduced by Fox Talbot in 1834), with the result that when the paper was sensitised there resulted silver chloride, together with a complex compound of insolubilised albumen and silver, as well as an excess of silver nitrate, this latter being quite necessary for sensitive paper and for a vigorous result. This form of paper gave prints with considerable gloss, and was known as 'albuminised silver' paper. Soon after introduction it became extensively used, and was employed by photographers as the chief silver-printing process until about 1892, when it was gradually replaced by the growing use of gelatino-chloride of silver emulsion paper. As well as albumen and ammonium chloride, gelatine and ammonium chloride was used. Such paper had no gloss after sensitising upon silver nitrate solution, and was known as 'plain paper.' In 1864 Wharton Simpson worked out a process for the production of a 'print-out' emulsion, suitable for application to paper and glass, which contained silver chloride, silver nitrate, and citric acid; and in 1881 Abney introduced a print-out gelatine emulsion containing silver chloride and silver citrate, there being no free silver nitrate present. 'Self-toning' papers, which contain the gold salt in the emulsion and complete the toning during fixing, effect a considerable simplification, and are still used to some extent, but the convenience and speed of working of bromide developing-out papers has very greatly reduced the amount of 'print-out' paper or 'P.O.P.' used for ordinary work.

Chromium Processes.—In 1839 Mungo Ponton (foreign secretary then to the Society of Arts for Scotland) observed that paper impregnated with potassium bichromate darkened upon exposure to light, and he suggested the employment of such paper in lieu of that containing a silver salt. The darkening was due to the reduction of the chromium salt in the presence of the material used for sizing the paper—probably glue. In 1855 Poitevin patented a method of printmaking by exposing a mixture of gelatine and a bichromate to light, the gelatine becoming insoluble in warm water. In this way the gradations of the negative were rendered by various amounts of insoluble gelatine which contained in suspension a colouring matter. This idea was more fully carried out by Ponney in 1859; but because of the fact that he exposed his sensitive surface from the front he failed to produce more than two tones—black and white; a defect which Burnett tried to overcome by reversing the operations and printing through the paper support. Improvement was made by Faigier in 1860 by coating the face of the exposed paper with collodion, which was then removed by soaking the combination in warm water, the collodionised coated gelatine film being received upon glass for development. Little advance, however, was made until the difficulties were attacked by J. W. Swan and his eventual associates Johnson and Sawyer, to whose labours the perfection of the carbon process is almost entirely due. The method as worked at the present day is extremely simple. A sheet of paper coated with gelatine, colouring matter, and potassium bichromate (carbon tissue) is exposed to light under a laterally reversed negative. It is then soaked in water together with a sheet of paper coated with colourless insolubilised gelatine, and the two are squeezed into close contact and kept for a short space of time under slight

pressure. They are then placed in water at 100° F., when, after a short time, the tissue backing-paper is easily detached, and on laying with water the soluble unchanged gelatine washes away, leaving the picture in insoluble gelatine behind. The picture is then rinsed in clean cold water, soaked in a solution of alum, rinsed again, and dried. This is the single-transfer process. If an ordinary unreversed negative is to be printed from, the exposed sheet is transferred for development to a piece of prepared opal or paper, and the image is eventually transferred again to another sheet of paper. This is the double-transfer process. Except in those rare instances where carbon tissue is prepared with fugitive pigments, carbon prints are quite permanent.

A film of gelatine containing potassium bichromate exposed to light loses its power of absorption of water, and therefore of swelling to a degree proportionate to the exposure. If, therefore, a sheet of prepared paper be exposed under a negative, and be afterwards placed in cold water, the swelling will vary according to the tones in the negative. If the excess of water be removed with a clean cloth, and a bush charged with lithographic printing ink be applied to the surface of the exposed and damp paper with a dabbling motion, in a little time the ink will be taken by the film in proportion to the degree of swelling, little in the least exposed and most swollen parts, and the greatest amount in the darkest tones, where the gelatine has been rendered insoluble, and consequently has not swollen. This is termed 'oil-printing.' In skilful hands it is capable of yielding results of considerable beauty, and because of the amenability to control is much used by pictorial photographers. A modification of this process is 'bromoil,' due to Mr C. Welborne Piper. In this process a suitable bromide print is treated with a solution containing an alkaline bichromate, bromide, ferrocyanide, alum, and citric acid. The bleached print is rinsed with water, treated for a minute or two with a 5 per cent solution of sulphuric acid, washed and fixed, and is again washed, when it is treated as an oil print. Many modifications of the bleaching solution have since been used, and the process is very popular.

Platinum Prints.—In the prints produced by the platinumotype process the image consists of metallic platinum, which is produced by the intermediary of the reducing action of an iron salt—viz. ferrous oxalate. In 1873 W. Willis, taking advantage of the reducing action of ferrous salt, produced prints the images of which were platinum. He prepared his sensitive paper with a coating of potassium chloroplatinate, silver nitrate (or lead nitrate), and ferric oxalate. This was dried and exposed under a negative, and subsequently floated upon a hot solution of potassium oxalate. The ferrous oxalate formed by light was dissolved by the potassium oxalate, and at the moment of solution it reduced the platinum salt with which it was surrounded, and an image in platinum resulted. An improvement was made in 1878, when the silver was eliminated, and paper was produced coated with potassium chloroplatinate, lead chloride, and ferric oxalate, and the prints were developed upon a solution of potassium oxalate containing potassium chloroplatinate. In 1880 another patent was taken out for a modification in which the paper was coated with the platinum and the iron salt alone, the prints being developed upon a solution of potassium oxalate; subsequently washed in water acidified with hydrochloric acid to remove the whole of the iron salt, and finally in plain water. This is the process so largely in use at the present day, furnishing results of extreme beauty and quite permanent. The scarcity of platinum during the Great War led to the introduction of

palladium as a substitute, but this class of process is now used only for very high-class work.

The processes hitherto described have been such as require the use of daylight for printing, or are light of high intensity. The halide salts of silver are, however, employed for the production of sensitive papers, by means of which short exposure to lights of low intensity, as gas, lamp, or candle light, suffices when the exposed image is subjected to development as in negative making. Such papers are known as bromide or chloride papers, these being the halides used. The first bromide paper was introduced by Peter Mawdsley in 1874, and since that time much skill has been shown in the preparation of papers of different kinds to suit all classes of negatives, both for contact-printing and for enlarging. By the use of silver chloride a particular class of emulsion papers is produced, known as 'gaslight,' the original of which was due to the labours of Baekland in the United States. The advantages of these gaslight papers lies mainly in their allowing manipulation in a much stronger light than is possible with ordinary bromide papers, and hence there is greater convenience in the dark room. The great majority of modern photographic prints are made either on bromide or gaslight papers, which are manufactured in a wide range of qualities and surfaces from glossy to that of the roughest water-colour paper. A considerable variety in tone can be produced by modification of the conditions of development, and further changes can be produced by converting the image into sulphide, or by toning with ferricyanide and suitable salt of iron, copper, uranium, &c. Developed prints upon bromide and chloride of silver papers are also used for the production of carbon prints by indirect means, as in the 'ozobrome' process of Manly introduced in 1906. Insolubility is produced in the gelatine by squeezing a bromide print into contact with a sheet of carbon tissue which has been soaked in a solution containing an alkali bichromate, bromide, and ferrocyanide.

Photographs in Colours.—Seebeck, making some experiments with chloride of silver in 1810, found that this body, when exposed to the spectrum, became changed, and in place of the normal gray or grayish-violet colour obtained by exposing to ordinary daylight, the substance changed differently under the various spectral hues. In the violet the chloride became reddish-brown, sometimes inclining to blue or violet, in the blue to a blue fading away towards the green to a lighter shade. No change took place usually in the yellow, but sometimes a pale-yellow tint was produced, and in the red and beyond the colour produced was pale red or lilac. There appears to be little doubt that this was the first observation of colour produced by the action of light upon a sensitive body. Since that time numerous workers—Wollaston, Nicéphore de Niepce, Herschel, Hunt, Poitevin, Becquerel, Simpson, Zenker, Carey Lea, Wiener—have obtained similar effects; but though the results furnished material for interesting and valuable speculations, they have not contributed very greatly towards the fulfilment of photography in colours as usually understood. Wiener conceived a black, light-sensitive surface composed of yellow, pink, and greenish-blue elements, each of which absorbs and is totally bleached by coloured light approximating to one of the colour sensations. This surface would be bleached to white by white light, to red by red light, yellow by yellow light, and so on. Among numerous attempts made to realise this conception the most successful worker has been Dr J. H. Smith, who introduced a black film paper in 1906 with one coating much more sensitive to light than had been previously produced. Dr Smith made a further

improvement in this so-called 'Uto' paper in 1911. The sensitiveness—rapidity of bleaching—is enhanced by the addition of certain substances, of which anethol is one, but the material was far too insensitive to be used in the camera, and could only be used for contact printing under a coloured transparency.

Becquerel exposed to coloured light a layer of the halide produced by electrolytic means upon a silver plate, and obtained a coloured image, which Zenker in 1868 stated was due to the structural alteration in the film. Zenker's hypothesis was that the colour was produced by the so-called stationary or standing waves, which was confirmed by Wiener in 1889, but more completely by Lippmann, who communicated to the French Academy of Sciences on 12th February 1891 the details of the colour process now associated with his name. According to Zenker, if two similar systems of light-waves meet, which occurs when a ray of light is reflected back along the same path as that of its incidence, there is produced interference, which results in a wave system where the crests and the nodes of the waves are not progressive as in ordinary light-waves, but are stationary. If such stationary waves are produced in a particular kind of sensitive film, the result is that strata of the particular product of the light action occur. If the layers be transformed into permanent form (as the silver produced by development of an exposed plate), and be again illuminated, they will reflect light of the same wavelength as the original light, and in consequence the same colours will result.

In the process of Lippmann a glass plate is coated with a very thin film of a grainless transparent bromide of silver emulsion. It is then exposed in the camera to the image of a coloured object, with the glass side of the plate facing the lens. In contact with the back of the film is a layer of clean, pure mercury, which forms a reflecting-mirror, and the light which traverses the film is reflected back again, when the reflected light meets the incident light and stationary waves are produced, and these produce the effect in the film. The plate is afterwards developed, fixed, washed, and dried. The method of Lippmann is of great scientific interest but is difficult in operation, and the process has found few workers.

All the successful methods of colour photography in regular use are due to the application of the Young-Helmholtz theory of colour-vision. In brief, this theory postulates that our colour-feeling is due purely to a physiological sensation produced by the stimulation of certain nerve fibrils. It is assumed that there exist in the eye three sets of fibrils which respond to certain influences, the results of which are termed 'fundamental colour sensations.' *Particular regions* in the spectrum of white light, a red, a green, and a blue, excite the nerve fibrils to a maximum effect, and these are termed 'the sensation hues.' If a particular amount of stimulus be applied to each one, the combined effect is the sensation of white, to the red and green alone the sensation of yellow, which inclines to orange or to green according as the red or green predominates. Any colour of the spectrum, and therefore any colour in nature, may be produced by the stimulation of one or more of the fundamental sensations—i.e. produced by mixture of certain proportions of the sensation hues. If we can analyse the colour composition of any coloured object—i.e. resolve it into three components which are identical in form—we can utilise such to produce the appearance of the object by synthesis, using the fundamentals. That it was possible to regulate such mixture by photographic means was first expressed by Clerk-Maxwell at a meet-

ing of the Royal Society of Edinburgh in 1855. Three photographs of the object are produced by photographing the object upon a suitable sensitive surface (a panchromatic dry plate or collodion emulsion) through three adjusted transparent colour-screens respectively, a red, a green, and a blue, by which operation we obtain records of the colours of the object in terms of the fundamental lines. Thus, in the three negatives made through the screens, white will be opaque and of equal value, pure green in the object will be represented in the negative made through the green screen as opaque, in the two other negatives as transparent, and so on. The negatives must all be equal in size. In applying the principles given two methods are open, the synthetic and the subtractive. The synthetic method involves the adding together of three *lights* corresponding to the three sensation hues, the summation of the three resulting in the sensation of white. The subtractive method *starts* with white light, or a surface reflecting white light such as white paper, and subtracts the colours affecting each sensation in turn, the total subtraction giving black. The hues of the dyes or pigments used in the subtractive methods are therefore *complementary* to the colour sensations they subtract. The subtraction of the red sensation is effected by a dye absorbing red, and reflecting white minus red, which appears greenish-blue. The dye which absorbs the green is a magenta-pink, and that which absorbs the blue is a yellow. The first to apply the principles practically was Louis Ducos du Hauron, who in a work published in 1869 (*Les Couleurs en Photographie*) gave practical instruction for the production of colour pictures by synthesis so far as it was possible under the then existing circumstances.

In 1888 F. E. Ives showed at the Franklin Institute a method of producing colour pictures, working according to the Young-Helmholtz-Maxwell principles on the synthetic method, by optical superimposition of three photographic images in their sensation hues by means of the lantern. Some time afterwards the same principles were followed in the construction of an apparatus termed the heliophotochromoscope (eventually kromscope).

In 1889 Ives published his first method of making lantern-slides on the subtractive principle. Using a blue ferrous sulfate print in gelatine from the red screen negative, he combined with it a reversed 'wash-out' gelatine print stained with eosin (pink) on another glass from the green screen negative, and mounted these face to face with a yellow collotype print (see below) on gelatine from the blue screen negative. In this process it was possible to vary the rendering by manipulation. At a later date the pink and yellow prints were produced as gelatine images on celluloid. This method was afterwards elaborated by Mr Sanger-Shepherd, and is now used by a number of workers.

Using the synthetic principle we can proceed in another way. If we place side by side small discrete particles of three pigments matching the fundamentals, taking care that there are no interstices and no overlapping; and if, moreover, the elements of such assemblage are so small that when examined at the ordinary distance of vision these elements are not separately distinguishable by the eye, an optical mixture will be produced and the surface will appear white, though such white will be less bright than the original paper; a white of low luminosity—a neutral gray—will result. If there be only green and red particles yellow will be produced, green and blue, peacock-blue (greenish-blue). If there be an assemblage producing white, and by any means we can obliterate one set of the units, the residue will give the complementary hue to the one destroyed—take away

the red, the surface will appear greenish-blue. Such a surface may be formed of lines or dots or by irregular particles. In practice the difficulties attendant on the production of pictures upon an opaque ground by the synthetic method have not been overcome.

The principles just described are, however, the basis of the beautiful autochrome process of Lumière Brothers, introduced in 1904, which is the most successful of the so-called screen plate processes for synthetic heliochromy. The original idea for such dates back to Du Hauron in 1869, and was put into practice with fair success by Professor Joly of Dublin in 1896, who used a plate ruled with lines alternately red, green, and blue, which was placed in contact with a colour-sensitive plate during exposure to an image in the camera. From this negative—the image of which was in lines—a positive transparency was produced; and this, when backed by a screen ruled in a similar fashion to the 'taking-screen,' but with tints corresponding to the fundamental sensation hues, gave a picture in colour. In the process of Lumière Brothers the screen plates for 'taking' and 'viewing' are identical, and are necessarily combined with the sensitive surface. A sheet of glass is coated with a tacky medium, and is then evenly dusted with a mixture of transparent starch-grains coloured red, green, and blue-violet, and mixed in correct proportion to produce a neutral white. Such grains being irregular, the assemblage leaves interstices which are filled with black, and when the surface has been satisfactorily prepared it is coated with a transparent waterproof varnish. The sheet now receives over this film a coating of colour-sensitive gelatino-bromide emulsion, and the plates are dried. The plate is exposed in the camera with the glass side towards the lens, so the light before reaching the sensitive film must pass through the starch-grains, each of which acts as a colour-filter. The plate is afterwards developed. In the white parts of the picture light will pass through all three sets of starch-grains and act on the silver bromide, which will be reduced and form an opaque image on development.

If the picture contains any red, green, or blue-violet parts the light from those parts will pass through only the red, green, or blue-violet grains respectively, and on development the opaque image will obscure these respective grains, while the grains through which no light passes will remain covered by the unaltered, translucent, silver bromide. Other colours will be transmitted in varying amounts by two or more of the sets of grains and produce a corresponding opacity on development. An interesting case is that of a bright yellow which passes through both the red and green starch-grains, and on development causes both red and green to be obscured, while the blue-violet grains have only the translucent silver bromide over them, so the result is that only blue-violet light is transmitted. It will be seen that the colours are complementary to those of the original picture, and that we require a positive image in place of the negative one we have obtained. To effect this reversal the developed but unfixed plate is treated with a solution which is a solvent of silver but not of silver bromide. The grains which were obscured are now left clear, and the picture appears somewhat faintly in its natural colours owing to the obscuring action of the unaltered silver bromide now left in inverse ratio to the amount of reduced silver removed. The plate is washed, exposed to white light, and the developer again applied, reducing the silver bromide to opaque silver, and the picture appears in its full colours.

Other screen-plate processes have been produced on the same principles as the autochrome, but most

of these have employed a geometrical arrangement of the units instead of the haphazard irregularity of the starch-grain layer. In a geometrical arrangement, such as is employed in the Paget screen-plate, it is possible to have the sensitive emulsion on a separate glass from the screen, and the negative is developed and fixed in the usual way. From this negative a positive is made by contact-printing, and bound up in register with the screen plate or, preferably, a viewing screen of identical arrangement but slightly different colours.

The subtractive method has been adopted in a number of processes, most of which have aimed at the production of prints on paper, but none of these processes have been sufficiently successful to be widely used. The chief application of the subtractive method is in relation to the various processes of photo-mechanical photography (see next section) and printing (see ILLUSTRATION OF BOOKS).

PHOTO-MECHANICAL PHOTOGRAPHY.—Reference has already been made under the heading of *Chromium Processes* to the fact that the gelatine in a mixture of that substance with an alkali bichromate loses its solubility in warm water after exposure to light. The chromium salt becomes reduced, the chromium sesquioxide eventually formed uniting with the gelatine to form an insoluble body. What is true of gelatine is equally true of its degradation product, gelatose (fish-gel and the like), of albumen, of starch, and of gum-arabic. This change in solubility, and some physical properties which accompany such change, form the basis of a number of technically important processes in which photography is united with the printing-press in the production of pictures in printers' ink, processes which come under the heading applied to this section. Such processes supply the greater number of the illustrations produced at the present time, and are therefore of considerable importance. The following typical processes may be taken as examples: collotype and photo-lithography; *intaglio*, woodburytype and photogravure; *relief*, line and half-tone process blocks. The processes may be used in two ways, either for the multiplication of photographic pictures of natural objects in place of one of the printing methods belonging to pure photography, or for the reproduction of copies of drawings and paintings. For the former all but the line processes are admissible; that is to say, given a photographic negative of the natural object, copies may be produced by any of the processes given. Any process may be employed for reproduction of drawings and paintings, but it will be obvious that the line block and line photo-lithographic processes can only be used for the multiplication of copies of drawings already existing in line.

Commercially, those processes are the most important which can be employed in conjunction with type, so that picture and text matter can be produced at one and the same printing, and for this purpose the line and half-tone relief methods are the only ones available. On the other hand, from the purely æsthetic aspect the processes of photogravure and collotype are far superior, although the cost of production is relatively higher than the other methods. See ILLUSTRATION OF BOOKS.

Collotype.—The surface of a sheet of ground-glass is coated with albumen and sodium silicate, and dried, heated, and washed in water. It is afterwards covered with a solution of gelatine and potassium bichromate in water, and dried by evaporation at an elevated temperature. This is exposed under a negative, washed, and dried. The surface is then moistened with ammonia, water, and glycerine until the film is softened, the excess removed, and the plate fixed in the printing-press. If a leather roller charged with a thin coating of

varnish ink (linseed varnish and pigment) be rolled to and fro over the surface, the ink will be transferred to the film, and will be taken by the different parts of the surface in direct proportion to the original action of light. A sheet of paper is then laid over the inked surface and pressure is applied, when the ink is transferred to the paper. With care considerable numbers of prints can be obtained from a plate which may be printed either in a hand-press or in a machine. Any colour of ink may be used, and the process admits of the use of many different kinds of paper. The process is remarkable for the beautiful rendering of the gradations of the negative, and is capable of giving pictures of charming character.

Photo-lithography.—This process may be used for the multiplication of copies of line drawings, and is generally used in map and plan work. Suitable subjects may be reproduced either by the 'transfer' or 'direct' method. A sheet of paper coated with gelatine is sensitised by immersion in a solution of potassium bichromate and dried. It is afterwards exposed under a clear line negative, when the gelatine becomes changed (so as to be insoluble in water) under the lines. The sheet is coated with a thin film of fatty ink by means of a roller, and placed in water. The exposed line parts do not swell; the unexposed portions absorb water and swell. Under those conditions the latter will not retain ink against rubbing. By the application of a tuft of cotton-wool the ink from the unaffected parts can readily be removed, leaving the ink firmly attached to the lines. The transfer is dried, and afterwards dampened, laid on the surface of a clean lithographic stone, and pressure is applied. The ink by this operation is transferred to the stone. The paper is pulled away, the stone coated with gum solution, and dried. It is afterwards treated in the same way as the stone bearing an ordinary lithographic image. Paper prepared with a ferric salt is also used in place of the alkali bichromate. The transfers are equally applicable to the production of images on zinc and aluminium, both of which are used in surface printing in the lithographic manner. Images are obtained in the 'direct' method by coating the grained zinc or aluminium plates with bichromated albumen solution, exposing under a line negative, coating with ink, and developing in water. The portions of the albumen film not insolubilised by the light action dissolve out, and on gently rubbing with cotton-wool under water the ink comes away from these parts, leaving the image in hardened albumen with a covering of greasy ink which fulfils the conditions necessary for lithographic printing (see LITHOGRAPHY).

Photogravure.—A modern photogravure plate consists of a sheet of copper which has been selectively etched into intaglio. The ink-bearing portions hold ink in proportion to the light and shade of the subject represented, and this ink is afterwards transferred to paper. The process generally used is that known as the Talbot-Klic. Upon the surface of a sheet of polished copper a fine layer of resin or bitumen dust is deposited ('graining'), and is fixed by heat. From the negative a laterally reversed positive is made upon glass, and from this positive a carbon-tissue print which will be negative. The print is developed in the correct position on the grained surface of the copper plate and allowed to dry. This negative carbon image is termed the 'resist,' and its function is to regulate the action of the etching mordant, ferric chloride. All parts of the plate but the resist are protected by an impervious varnish, and the plate is then placed in the mordant. The fluid penetrates the different thicknesses of the resist in different times, and reaching the metal, etches it tone after tone.

There is thus a differential action, and as time goes on the copper is etched to different depths. When the action is completed the resist and grain are cleaned off, when it will be found that a series of cavities has been formed. The function of the 'grain' is to protect minute areas of the metal from the action of the mordant. A patch of uniform tone of appreciable size is not a cavity etched to a uniform depth, but is made up of a number of small ones (not separately distinguishable by the unaided eye), owing to this protective action of the grain. To produce a print the plate is covered with suitable ink (stiff linseed varnish and pigment), the excess of which is removed, leaving the surface clean and the ink for the picture in the cavities. It is at this stage that the 'grain' exerts influence, for if the cavities were of appreciable size the ink would be dragged out of the cavities in the operation of wiping the excess from the surface. The print is taken by pressure upon damp, soft, sized (plate) paper in the ordinary copperplate press, and success or failure to produce good pictures by the photogravure process is largely dependent upon the skill of the printer. Usually the plates require considerable modification at the hands of a skilful engraver, and by a process of selective etching by which certain portions are re-etched. Before printing any number of copies the plate is 'steel-faced' by electro-deposition.

Prints in colour are produced by a selective inking of the plates by hand by means of different coloured inks applied by sponges, dabbers, and stamps, and are printed, each copy, at one impression. Such prints are often very beautiful, but are extremely costly. During recent years pictures of a high standard have been produced at a low cost by means of 'rotary' photogravure. In this process the etched surface is cylindrical, and is prepared as above, except that the graining is replaced by a second exposure on the carbon tissue under a screen consisting of clear thin lines crossing at right angles on an opaque ground. The effect of this exposure is to form, in the carbon tissue, a network of hardened lines which are almost impervious to the ferric chloride. After etching, the surface of the copper, examined under a magnifying lens, somewhat resembles a very minute and extremely shallow honeycomb, with the cells of varying depth according to the light and shade of the picture. The 'ink' used is a fine pigment or dye suspended in a highly volatile spirit, and it is applied by a roller very liberally to the lower side of the etched cylinder as it revolves. Immediately above the ink roller a flexible steel blade presses lightly against the cylinder and removes all the ink that is not held in the cells except a very thin film which acts as lubricant and prevents the steel blade wearing away the etched surface. This thin film dries instantly, so that when the paper is pressed into contact with the cylinder on the upper side the only ink transferred to the paper is the moist ink contained in the cells.

The paper is generally fed from reels, not cut sheets, and as the motion is a perfectly continuous rotation, very high speeds can be attained. This process is now widely used for printing illustrated magazines and other purposes where the number of copies required is sufficiently large to cover the expense of preparing the cylinders. The process has recently been successfully employed for the production of pictures in colour, and, on theoretical grounds, the varying depth of colour deposited on the paper by this process makes it the most promising field for the application of the principles of colour photography by the subtractive method.

RELIEF PROCESSES.—*Line*.—A sheet of zinc coated with bichromated albumen or fish-glue is printed under a clear line negative, coated with fatty ink,

washed in water, when an image of insolubilised matter bearing fatty ink on its surface is produced. Upon this plate, by the application of dilute nitric acid, the bare portions of the metal corresponding to the whites of the drawing may be etched away, leaving the inked parts in relief, and when sufficient relief has been obtained an inked roller passed over the etched plate will ink merely the surface of the lines, which ink may be transferred to paper. In practice it is necessary to reinforce the sides of the lines from time to time to enable them to withstand the lateral action of an acid bath sufficiently strong to etch away the unprotected portions in a reasonable time. The amount of relief required for the lines depends upon the width they are apart—with close lines little; but when they are far apart considerable depth must be obtained. When the etching is complete the superfluous metal is cut away, and the plate is mounted upon a slab of wood to type-height, when it is ready for the press.

Tone.—Without modification the type-high process as described would not be able to represent a photographic portrait or landscape, or indeed any object existing in nature where the gradations of light and shade are continuous. But such subjects are represented, and the interest of the modern type-high 'half-tone' process, so called, lies in the optical device which is used to secure such representation. The system consists in translating the continuous tones or shading of the drawing or photograph into isolated masses or dots, the area of which in proportion to the area of white paper between them depends upon the brightness of the tone represented. If the units are small enough to be separately indistinguishable, or are viewed at a sufficient distance to make them indistinguishable, the illusion of smooth continuous tone will be produced. In the half-tone process this translation is effected by means of the 'ruled' screen, a sheet of glass ruled with a series of parallel opaque lines so that there are alternate dark and light spaces of equal width, the latter being the transparent glass ground. Two such plates are cemented with these ruled surfaces in optical contact, and this leaves a series of rectangular transparent openings. Given a drawing or a photograph from which a half-tone block is to be made, it is re-photographed, and during the exposure the ruled screen is supported close in front of but separated from the sensitive plate. The effect of this screen is to break up the shading into dots, which are largest in the brightest tone, and decrease in size to the darkest tone. From the negative a print in insolubilised bichromated fish-glue on metal—generally copper—is produced, which, after being strongly heated, forms a resist capable of withstanding the action of the mordant ferric chloride by which the dots are etched into relief. The relative tones can be altered by a system of selective etching termed 'fine etching,' the result of which proceeding is to vary the relation of the brightness of the tones, a method frequently necessary owing to errors in negative-making, in printing the resist, inherent limitations of the automatic process, and also to the fact that many originals are unsuitable to the process or furnish pictures not pleasing to those for whom they are intended. The plate, when etched, is trimmed and mounted type-high upon a block of hard wood, when it is ready for the printer (see ILLUSTRATION OF BOOKS).

Tricolour.—In principle the application of the three-colour system to the production of type-high printing-blocks for making pictures in colours is simple, although in practice there are many difficulties. Two methods are in vogue, the indirect and the direct. In the former three negatives are made of the object, equal in size, through colour-filters on the lens, red, green, and blue-violet, and

from these negatives suitable transparencies. From these screen negatives and process-blocks are produced. Impressions are superimposed upon one sheet of paper in yellow from the blue-violet screen block, in pink from the green screen block, and in greenish-blue from the red screen block. This process, which is necessary when making pictures of objects in relief, has been largely superseded by the direct process applicable to almost all classes of flat subjects in colour. In the direct process the colour negatives are made as screen negatives at one and the same operation upon special panchromatic dry plates or on collodion emulsion, with colour-filter on the lens and ruled screen in front of the sensitive plate. In this way negatives are produced which can be used for printing on metal, and intermediate operations are saved. The half-tone plates are produced as described above. In all cases they require very skilful 'fine etching' to render the appearance of the original subject with even a fair approximation to accuracy, and afterwards highly skilful printing. Frequently a fourth block is used in addition to the tricolour set, which is usually prepared from a photographic negative giving in the first instance a good monochrome rendering. Such a block, after correction, is printed generally in a dark gray or black ink, and permits the use of brighter colour inks without loss of depth in the shadows, or uncertainty in the grays. It also permits of a little more latitude in the printing.

Photometry (Gr. *phōs*, 'light,' and *metron*, 'measure'), the art of measuring the intensity of a source of light, by comparison with a standard of reference (see GAS-LIGHTING). The principles involved in the usual instruments are: (1) Lambert (1760), Rumford: equality of shadows cast by two sources at different distances; when the shadows are equal the intensities are proportional to the squares of the distances. (2) Equality of illumination through slits in screens; distances and intensities as before. (3) Bouguer, Ritchie, Leonard Weber: reflection of light from two sources, so that they travel side by side to the eye, the distances being adjusted until they appear equal; calculation as before. (4) Wheatstone, the same; but the two reflections are from a polished sphere, which is set in motion, so that the comparison is between two looped luminous curves, produced through the persistence of vision. (5) Bunsen: a grease-spot on paper, equally illuminated on both sides, disappears. (6) Babinet: light from one is polarised by reflection, from the other by refraction; both pencils are sent through a double rotating quartz, and looked at through a double-refracting prism; they give coloured images, and the distances are adjusted until the images, on over-lapping, give a white field. All these methods are unsatisfactory when the sources of light are of different colours, as—e.g. a candle and an arc-lamp. Instruments have accordingly been devised for applying the above methods to each part of the

spectrum of the light from each source. The degree of sensitiveness of the eye of the observer, or a difference of sensitiveness between his two eyes, affects the result. In the 'flicker' method of photometry, the two lights are made to illuminate a white screen in rapid alternation; if their illuminations of the screen be unequal the effect is a flicker; if these be equal the effect is smooth and continuous, even though the two sources differ widely in colour (Simms and Abady). In other instruments used as photometers what is measured is not the luminous intensity so much as the radiation: among these we may mention the Radiometer (q.v.); Leslie's photometer, which is a differential thermometer; Bunsen and Roscoe's, which measures the quantity of hydrochloric acid formed in a given time from chlorine and hydrogen; Léon's, which measures the amount of nitrogen liberated from iodide of nitrogen; and various instruments based on photographic reactions, which truly measure not the luminous, but the actinic intensity. Stellar photometry is generally contrived by stopping off more or less of the surface of the object-glass, or by polarising apparatus, so as to bring the apparent brightness of a star down to that of a standard of comparison. The usual photometric standards are (1) the English standard candle (see GAS, LIGHTING BY); (2) the Hefner-Alteneck amyl-acetate lamp, which has now displaced the candle in Germany; (3) the candle, a standard colza-oil lamp, used in France; (4) the Electrical Standards Committee's unit, the light given off by one square centimetre of platinum at its fusing-point; and (5), in scientific work, an incandescent electric-lamp under stated conditions of resistance and current, maintained constant.

Photophone, an apparatus for transmitting articulate speech along a beam of light, first described in 1880 by Graham Bell (see TELEPHONE). Its possibility depends on the peculiarities of the metal selenium. Crystalline selenium offers a high degree of resistance to the passage of an electric current; it is eminently sensitive to light; and the resistance is less when exposed to light than in the dark, being in some cases only a fifteenth in the light of what it is in the dark.

Founding on these peculiarities, Professor Graham Bell, his friends, and assistants devised some fifty forms of apparatus, for so varying the transmission of light to produce audible sound. In the photophone found most servicable the transmitter is a plane mirror of silvered microscope glass or thin mica; the receiver, fixed at a distance without any connection, is a parabolic reflecting mirror, in the focus of which is placed a sensitive selenium 'cell,' connected in local circuit with a battery and telephone. When the apparatus is used, a strong beam of light is concentrated by a lens in the plane mirror; the speaker directs his voice against the back of this mirror, which is thrown into vibrations corresponding with those of the voice. The reflected beam of light, to which corresponding vibrations are also communicated, is directed through a lens to the receiving mirror, and creates in the selenium cell a rapidly variable current, which at the end of the telephone attached becomes audible again as vocal sound. When first described, the photophone had been used effectively with a distance of 230 yards (over a furlong) between transmitter and receiver. The rays of the oxyhydrogen light, or of an ordinary kerosene lamp, suffice for transmitting articulate speech. The loudest sounds obtained from the photophone were produced by means of a perforated disc, noiselessly revolving so as rapidly to interrupt the light in transmission.

It was also found that a very audible sound could be procured from the selenium without the aid of

telephone and battery. A beam of intermittent light will produce a strong musical note from the selenium. Further experiment showed that selenium is not the only substance thus sensitive to light. Still louder sounds than those obtained from the selenium directly, though not articulate, were got from diaphragms of hard india-rubber and of antimony; and sounds of varying intensity were given out by many other substances, including gold, silver, platinum, copper, zinc, lead, paper, parchment, and wood.

Photosphere. See SUN.

Phrenology, Gall's name for the physiology of the brain, used especially for the system based on Gall's observations and theory. In Britain the system was amply expounded by Gall's pupil Spurzheim (q.v.), by George and Andrew Combe (q.v.), and by Dr Elliotson, founder and first president of the Phrenological Society; and in America by Dr Charles Caldwell of Kentucky, the brothers Fowler, and S. R. Wells. The connection of mind and brain was an old theory, and a kind of localisation of mental function in the brain had at various times been attempted from the days of Albertus Magnus downwards; but the first full-fledged system of empirical craniology or phrenology must be attributed to Gall, who established his scheme by inspecting the exterior of the heads of a considerable number of persons of different characters; and believing himself to find portions of the scalp corresponding to their mental and moral faculties, marked out on a model of the head the areas which were prominent in proportion to the strength of the various faculties. These faculties were by Spurzheim divided into two orders—Feelings and Intellect, or Affective and Intellectual Faculties. The Feelings were divided into two genera—the *Propensities* and the *Sentiments*; while the Intellectual embraced the *Perceptive* or *Knowing* and the *Reflective Faculties*. Various modifications of Gall's scheme of localising the faculties were made by his pupils. The new science made many converts and became popular in most European countries; but scientific study of brain and mind in their various relations have rendered it obsolete as a scheme. Gall was apparently no charlatan. He was 'a superb anatomist and demonstrator.' 'His contributions to the anatomy of the central nervous system are of far-reaching importance,' says Professor Elliot Smith, 'and to the physiology of the brain and to psychological theory he gave a new orientation and a new inspiration.' He made grotesque mistakes, however, and his followers have surrounded his name with an air of quackery, which has made it difficult till lately to be fair to him. For what is known of the localisation of functions, see BRAIN. Beyond this, as Professor Elliot Smith contends, 'There is something about the modelling of different parts of the skull, especially the forehead region just above the ears, which every human being seems able to interpret in a vague or general way as an index of the ability or the aptitude of the individual.' But a true phrenology has yet to be built up.

See GALL, SPURZHEIM, COMBE, SKULL, PSYCHOLOGY, PSYCHOLOGY; Bernard Hollander, *The Revival of Phrenology* (1903); Elliot Smith, *The Old and the New Phrenology* (1925).

Phrygia, a country in Asia Minor, the extent and boundaries of which varied very much at different periods of ancient history. In prehistoric ages it is believed to have comprised the greater part of the peninsula, but at the time of the Persian invasion it was limited to the districts known as Lesser Phrygia and Greater Phrygia—the former stretching along the shores of the Propontis

and the Hellespont to Troas (afterwards part of Mysia), the latter occupying the centre of Asia Minor. Phrygia was in general a high and somewhat barren plateau, though its pastures supported immense flocks of sheep, noted for the fineness of their wool. The most fertile part was the valley of the Sangarius, but the most beautiful and populous district was the south-west, at the base of the Taurus, where the Maeander and other streams had their rise. The mountains and streams yielded gold; Phrygian marble was celebrated, and the vine was much cultivated. The Phrygians are now held to have been Aryans who came into Asia Minor through Macedonia and Thrace, disturbed the Hittites (q.v.) in the 12th century B.C., but were at first repulsed and then influenced by Hittite culture. By 718 B.C. the Phrygian Midas (q.v.) had broken the Hittite power and shared most of the Hittite territory with the Assyrians. Croesus had conquered Phrygia c. 549 B.C. and succumbed to the Persians. Phrygian religion deeply influenced Greek mythology. Among their deities were Cybele, the Mother, and Sabazius (Oloresis, Attis), the Son; and Aithys, and Phrygia was a great centre of orgiastic worship.

See Sir W. M. Ramsay's *Cities and Bishoprics of Phrygia* (1895-97); D. G. Hogarth, in the *Cambridge Ancient Hist.*, iii. (1925) chap. xxi. For the Phrygian Mode, see HARMONY; for the Phrygian cap, see IONNET.

Phryne, a celebrated courtesan, was the daughter of Epicles, born at Thespia in Boeotia, and originally earned a livelihood by gathering capers; but as the fame of her marvellous beauty spread she obtained numerous lovers, who lavished gifts on her so profusely that she became enormously rich. In proof of this the story goes that she offered to rebuild the walls of Thebes if the citizens would allow her to place this inscription on them: 'Alexander destroyed them; Phryne, the courtesan, rebuilt them.' The Thebans declined the proposal. Her enemies accused her of profaning the Eleusinian mysteries. Summoned before the tribunal of the Heliasts, she was defended by the rhetorician Hyperides, one of her lovers, who, perceiving that his eloquence failed to convince the judges, threw off her robe and showed her naked loveliness. She was immediately acquitted, and carried in triumph to the Temple of Aphrodite. The famous 'Venus Anadyomene' of Apelles is said to have been a portrait of Phryne. Praxiteles, also a lover of hers, employed her as a model for his 'Cnidian Venus.'

Phrynichus, (1) an Athenian tragic poet, who gained his first dramatic prize in 511 B.C., twelve years before Aeschylus, and his last in 476, when Themistocles was his *choragus*. He seems to have gone to the court of Hiero in Sicily, and to have died there. He introduced masks representing women, and to the light mimetic choros of Thespis added the sublime music of the dithyrambic choruses. His most famous tragedies were the *Phryniassa*, which is supposed to have inspired the *Perse* of Aeschylus, and another which had for its subject the capture of Miletus by the Persians. So overpowering was its effect that the audience burst into a passion of tears, fined the poet a thousand drachmae for so harrowing a description of the sufferings of a kindred people, and forbade the piece ever again to be represented. His scanty fragments will be found in Nauck's *Tragicorum Graecorum fragmenta* (1887).

(2) A poet of the old Attic comedy, who was honoured by the abuse of his great contemporary Aristophanes (*Ran.* 14) for his low buffoonery. His fragments are collected in Meineke's *Fragmenta Comicorum Graecorum* (1839-57) and Koch's *Comicorum Atticorum fragmenta* (1880 et seq.).

(3) A Greek grammarian and sophist who flourished under Marcus Aurelius, and wrote a collection of select specimens of Attic usage intended for the benefit of his friend Cornelianus, secretary to the emperor. It consists of about four hundred short unconnected *dicta* on the orthography, signification, and use of particular words, and upon the rules of accident, especially in verbs. The edition by Lobeck (1820) was followed by *The New Phrynichus*, by W. Gunion Rutherford (1881).

Phrynosome (*Phrynosoma*), a genus of squat Iguanid lizards with keeled scales on the body and sharp bony spines on the head, badly called 'Horned Toads.' They live in arid sandy places in the western half of the United States and Central America; and their yellowish, gray, brown, black coloration is well suited to conceal them against their sun baked background. They are often about five inches long. Their food consists of small insects, which are caught by rapidly shooting out the tongue. They require water in the shape of dew or drops; they bask in the sunshine by day and bury themselves in the sand for the night. During the winter they lie comatose and hidden. About a dozen species are known, all viviparous. Their peculiarities are many. They look like miniatures of some of the extinct horned reptiles; they pass into a hypnotic state when the top of their head is stroked, when much irritated they squirt drops of blood from their swollen eyelids.

Phthiotis, the south-east corner of Thessaly (q.v.), the home of Achilles.

Phthisis. See TUBERCULOSIS.

Phylactery (Gr. *phylakterion*, 'an amulet'), the name given in the New Testament to small square boxes of parchment or black calf-skin, containing strips of parchment or vellum with certain texts of Scripture (Exod. xiii. 2-10, 11-17; Deut. vi. 4-9, 13-22) written on them. The phylacteries are worn on the left arm and on the head by all Jews (except Karaites) above thirteen years of age on week-day mornings during the time of prayer. This is done in accordance with their interpretation of Exod. xiii. 9-16. Some Russian and Polish Jews wear phylacteries all day; and they have at times been worn as amulets against demons. The writing of phylacteries is in the lands of privileged scribes (*Saferim*) only, and many and scrupulous are the ordinances which they have to follow in the execution of this task.

Phyllite, a schistose clay-rock, containing a variable proportion of quartz in grains, together with mica, usually chlorite, and sometimes many accessory minerals. The rock is more crystalline than clay-slate, and passes into mica-schist. The surfaces of the folia in phyllite are frequently finely wrinkled.

Phyllocladus, a genus of Taxaceæ with so-called phylloclades, that is, leaf-like expansions arranged along the axial growth, performing the functions of leaves. Such phylloclades, it may be mentioned here, are very common amongst the Australian wattles, where they present the most diverse forms. True leaves appear in the juvenile state of *Phyllocladus*, to disappear in the third year and to be represented during the adult state by minute scales at the bases of phylloclades. *Phyllocladus* is dioecious and monocious. The fruit resembles that of the yew. There are four species in New Zealand and Tasmania: *P. glauca* (vernacular, tota-ton); *P. trichomanoides* (tane-kaha); *P. alpinus* (the celery-pine), all in New Zealand; and *P. asplenifolius* (celery-topped pine), in Tasmania. *P. hypophyllus* is found in Borneo, *P. protractus* in Papua and the Philippines.

Phyllopora. See CRUSTACEA.

Phyllotaxis. See LEAF.

Phylloxera (Gr. *phylon*, 'a leaf,' and *xeros*, 'dry'), a genus of insects belonging to a family (Phylloxerinae) nearly related to aphides and coccids insects, and included within the sub-order Homoptera in the order Hemiptera or Rhynchoptera. Two or three species occur in Europe, living like many related forms as parasites on plants. Most important is *P. vastatrix*, which ravages the vine, and has cost France alone a pecuniary loss far exceeding that of the Franco-German war. It seems to have been discovered in North America in 1854, and in all likelihood was carried thence to Europe, where it appeared about 1863. It now occurs in all vine-growing countries. In some of its features it is like a little aphid, measuring about $\frac{1}{16}$ th of an inch in one of its stages, or only a fourth of that in others, varying from yellow to reddish brown in colour. The antennae are thick,

Life-history of Phylloxera (from Leunis).

A, a winged female; B, a wingless female from the root; C, under surface of a vine-leaf, showing the wart-like galls; D, an enlarged section of one of the galls, showing the eggs within it; E, upper surface of a vine-leaf, showing the openings of the galls; F, some of the roots of the vine, showing the nodosities caused by the parasites.

with three joints; the legs are short and thick; there is no trace of the 'honey-tubes' characteristic of aphides; the winged forms, which are all parthenogenetic females, have four wings. As in the nearly related genus *Chermes*—a destructive parasite of conifers—the life-history is exceedingly complex.

Let us begin with the winged females, which in Europe appear from August to October. Each lays about four parthenogenetic ova on the under surface of the vine-leaves. These ova develop in late autumn into males and females—wingless and without the characteristic piercing and sucking mouth-organs—which migrate to the stem of the vine. There each female lays a single egg under the bark. This egg lies dormant throughout the winter, and develops in April or May into a wingless but voracious 'vine-louse.' This form may pass to the leaves, on which it lays parthenogenetic eggs, and forms galls; but in Europe it attacks the roots, and lays its eggs there. From these in about eight days young develop, which become mature females in about twenty days, and lay more eggs in the roots. Half a dozen or more of these parthenogenetic generations follow in rapid succession throughout the summer. The roots become knotted and deformed; the whole plant suffers, and, though it may survive for several seasons, eventually dies.

In midsummer, among the subterranean forms, generation is born whose members, after four, in stead of the usual three, moultings associated with adolescence, become the larger winged females with which we began.

The destruction of this scourge of the grape-vine, without also injuring or destroying the plants, long proved almost impracticable, owing to the difficulty experienced in reaching its subterranean haunts without disturbing or destroying the roots. Water, wherever it can be applied to the soil so as to saturate and keep it saturated for a time, has proved a safe and effectual destroyer, because the insect cannot live in a medium saturated with water for long. Chemical remedies, such as bisulphide of carbon, have been employed experimentally with success, but are found to be too expensive for general application on a large scale, even were the practical difficulty of conveying them into all depths of the soil and diffusing them in it surmountable. Several cases of attacks of phylloxera on vines in vineries in England have occurred since 1865. These attacks have been usually met by the process of 'stamping out.' The vines were destroyed by burning, the earth in which they grew was wholly removed, the walls of the vinery and the floor of the border on which the earth rested were thoroughly cleansed with salts or corrosives, and a fresh start was made with new earth and new vines; but while practicable to this limited extent, the remedy is obviously inapplicable to vineyards in districts collectively covering thousands of acres. In some of the French vineyards grafting the cultivated vines on certain of the native vines of America, or replanting the vineyards with American vines was found the most effective remedy. Although the insect seems to feed on the roots of these vines, the greater vigour of the American stocks appears to enable them to resist the injuries inflicted on them. Sulpho-carbonate of potassium is another chemical aid. Another method tried is the cherishing and multiplication of the numerous natural enemies of the phylloxera—*Hopliophora arctata*, *Polycenus laqueus*, *Thrips*, *Aphidius*, &c. The devastations were not serious in Austria and Portugal till 1872, in Germany till 1881; the Cape, Algeria, and Australia were reached in 1880-85; but France (q.v.), suffered by far the most. Other species or varieties occur on the oak, the hickory, the chestnut, and the willow.

See M. Cornu, *Études sur le Phylloxera vastatrix* (1879); J. Lichtenstein, *Histoire du Phylloxera* (1878); Planchon, *Les Mœurs de la Phylloxera* (1877); Dreyfus, *Ueber Phylloxeracium* (1889); Majet, *Les Insectes du Vigne* (1890); and Tavernier's *Report on the phylloxera in Victoria* (1899).

Phylogeny (Gr. *phylon*, 'race,' and *genesis*), a biological term applied to the evolution or genealogical history of a race or tribe. It is used in contrast to 'ontogeny'—the development or life-history of an individual; witness Haeckel's 'biogenetic law': 'Ontogeny is a recapitulation of Phylogeny.' See DARWINIAN THEORY, EMBRYOLOGY, EVOLUTION, HEREDITY.

Phyong-yang (Jap. *Heijo*), the leading city of northern Korea, historically important; pop. 86,000.

Physalia. See PORTUGUESE MAN-OF-WAR.

Physalis, an American genus of Solanaceæ. See CAPE GOOSEBERRY, WINTER CHERRY.

Physeter. See WHALE.

Physical Chemistry. The recognition of physical chemistry as a distinct branch of natural science may be said to date from the foundation of the *Zeitschrift für physikalische Chemie* by Ostwald in 1887.

The first volume contained an account by Van't Hoff of the analogy which he had shown to exist between gaseous pressure and the osmotic pressure of a substance in solution, and another by Arrhenius developing his theory of the electrolytic dissociation of substances dissolved in water. The following year Ostwald was made professor of Physical Chemistry at Leipzig, which became the centre from which early enthusiasm for the subject radiated. He was joined by Nernst, who developed the theory of the electromotive force produced by the solution pressure of ions, by Arrhenius from Sweden, by Beckmann, who worked out the methods of molecular weight determinations based on the new theories, and by a succession of men since distinguished by the success of their labours in applying the principles and methods of the more exact and more abstract science of physics to the problems arising from the rapidly-increasing mass of chemical data. Journals have since been founded in America, France, and England dealing exclusively with physical chemistry.

On the experimental side, the physical chemist applies the methods and apparatus of the physical laboratory to the practical problems of chemical change, measuring changes of energy, determining the velocity and acceleration of chemical change, and the conditions of equilibrium, the dependence of these upon temperature, upon the medium, upon adiation and electric charge. He uses the calorimeter, the thermocouple, the galvanometer, the electrometer, the spectroscope, polarimeter, refractometer—in fact, the whole range of physical instruments. On the theoretical side he accepts those laws of physics which are most fundamental, and have been most firmly established, the first and second laws of thermodynamics, the kinetic theory of gases, the laws of electrostatics and electro-magnetism: a physical chemist discovered the third law of thermodynamics, and several of the Nobel prizemen in chemistry have utilised almost entirely the methods of physics. As regards theories of radiation, physics has not yet emerged from a state of revolution, and the physical chemist remains in a state of some perplexity and suspense.

Atomic Theory (q.v.).—The existence of atoms and molecules is no longer to be treated as a matter of speculation or mere theory, but as established fact. Though it is not possible to see a single unelectricified atom, yet the tracks of single atoms can be seen and photographed (charged helium atoms, so-called *particles*). The fortuitous motion of very small particles (Brownian motion) can be seen with the aid of the ultra-microscope, and resembles the hypothetical motion of the molecules of a gas. It is not the existence of the atom but its structure which is now the subject of discussion and investigation.

The following data indicate the kind of exact knowledge now acquired about the atom and molecule:

The weight of an atom of hydrogen = 1.66×10^{-24} gram.

The diameter of an atom about = 1×10^{-8} cm.

The number of molecules in a gram-molecule = 6.06×10^{23} (Avogadro number).

The distance apart of the atoms of sodium and chlorine in a crystal of common salt = 2.81×10^{-8} cm.

Structure of the Atom.—The theory now generally accepted is that an atom consists of a central nucleus of positive electricity, of which the diameter is of the order 10^{-13} cm., round which are grouped electrons over a sphere of radius about 10^{-8} cm. It may be compared to the solar system. There are at present two working hypotheses—one, due to Sir J. J. Thomson, and extended by Kossel, G. N. Lewis, Langmuir, and others, regards the electrons as occupying or oscillating about positions of equilibrium in the atom, and this is the most convenient

model for the chemist to use when dealing with atoms in ordinary chemical change, not emitting light; the other, due to Bohr and elaborated by Sommerfeld and others, postulates motion of the electrons in orbits round the nucleus, and this model has achieved marvellous success in accounting for the spectrum of hydrogen and helium. The electron is supposed not to emit radiation while describing its orbit, but when it drops from one orbit to another with loss of energy it emits light of wave-length exactly determined by the 'quantum' of energy lost, and when it absorbs light it does so by receiving a 'quantum' of energy exactly sufficient to enable it to jump into another fixed orbit. The discovery of radium and the study of radio-activity, notably by Rutherford, has led to knowledge of the structure of the atom which previously was beyond the range of speculation. Not only was it found that well-known elements were formed by the spontaneous disintegration of heavier ones, but, further, that the products of radio-active change resulted in the formation of elements which, though chemically identical, possessed different atomic weights. For such the name *isotope* was coined by Soddy. Later, in 1919, Aston, by a refinement of existing methods of examining the positive rays produced by the electric discharge in rarefied gases, showed that the ordinary stable chemical elements were in many cases *mixtures* of isotopes, so that the atomic weights obtained for them by chemical methods were merely averages: the atomic weight of each isotope is a whole number (oxygen = 16). One important result of this was the removal of long-outstanding difficulties in the periodic table of the elements.

As the result of work on X-rays begun by Moseley in 1913, it is now known that the frequency of vibration of the X-rays which are characteristic of an element depends on the *atomic number* of the element. On the present nuclear theory of the atom it is considered that the atomic number is equal to the number of units of positive charge on the nucleus, and both are equal to the number of electrons surrounding the nucleus. The periodic law in the light of these new facts is a necessary outcome of atomic structure, the chemical properties of the elements depending on the number, arrangement, and stable configuration of the electrons. Thus, the atomic number of sodium is 11, it comes eleventh on the list of elements, and is regarded as containing a positive charge of eleven units and eleven electrons round the nucleus.

The difficulties which beset the theory of the atom affect the chemist chiefly when the theory is applied to molecules. The crystallography founded on work with X-rays has greatly increased our knowledge of the relative positions of the atoms in solids; in a crystal of rock-salt, for example, molecules do not exist as they do in gases; the atoms are held together by the electrostatic forces between the electrons of all the adjacent atoms and not merely by attraction in pairs. In the case of sodium and chlorine the union to form a molecule is probably the result of a loss of one electron by the sodium atom and the gain of it by the chlorine; the latter will have become negatively charged, the sodium positively: thus, the molecule is held together by the resulting electrostatic attraction between the two; the atoms in the chlorine molecule itself are regarded as held together by the sharing of two electrons. The problem of molecular structure has developed into the problem of locating the relative positions, not only of the atoms as a whole, but also of the electrons, and thus another bridge has been thrown across the gap separating chemistry from physics.

Gas Laws.—The major part of physical chemistry in the past has been the study of the well-known

gas laws in their application primarily to chemical change among gases and their extension to solutions, liquids, and solids.

The behaviour of a gas when subjected to changes of temperature, pressure, and volume is summed up in the statement that, for a given mass of gas, $pV = RT$. If the pressure is taken as one atmosphere and the volume as 22.4 litres, T the absolute temperature 273 (0°C.), then the value of the gas-constant, R , is .082, or in heat units nearly 2 calories per degree. For low temperatures or high pressures or for vapours near their condensing-points, deviations from this simple law become marked. In such cases the equation of Van der Waals is employed
$$\left(p + \frac{a}{v^2}\right)(v - b) = RT$$
 where a denotes the coefficient of attraction between the molecules and b is four times the volume of the molecules.

The conception of a gas elaborated in the kinetic theory of gases regards the gas as composed of an enormous number of particles in rapid rectilinear fortuitous motion, making a prodigious number of collisions per second, so that their paths are exceedingly short. In a mixture of gases the heavier particles move more slowly, but the average energy of all particles, light or heavy, will become the same (equidistribution of energy).

Avogadro's hypothesis is a simple deduction from the theory which shows that equal volumes of gases under the same conditions contain the same number of molecules, and Graham's law of diffusion also follows—viz. that the rate of diffusion of a gas is inversely proportional to the square root of its density.

Liquids can be treated as very imperfect gases, and in dealing with them Van der Waals's equation may be used.

In a solid the forces between the particles are strong enough to prevent them wandering about, but if the temperature is raised the amplitude of vibration increases until at the melting-point they begin to slide over each other. Even in solids the molecules at the surface have sufficient energy to fly off and form vapour, the pressure exerted increasing as the temperature increases. This vapour-pressure is much greater for the liquid than for the solid, and at a definite temperature it has a definite value. If the substance is contained in a closed space, the molecules will be continually striking the surface, and the rate at which they condense will be exactly the same as the rate at which they fly off; on raising the temperature, the rate of escape increases more rapidly than the rate of return, and the vapour-pressure increases. When the pressure reaches that of the atmosphere, the temperature is called the ordinary boiling-point.

Osmotic Pressure.—If a solution of sugar is placed in a tube, the bottom of which is closed by a membrane, and the tube immersed in water; the level of the liquid in the tube will rise slowly owing to water passing in from below. Such a membrane, which allows water to pass through but not sugar, is called *semi-permeable*. As the level rises, the pressure on the inside of the membrane increases, and this will continue until it is sufficient to counteract the tendency of the water to come through. This phenomenon is known as osmosis, and the pressure as osmotic pressure. The apparatus can be modified so that the solution does not become appreciably diluted, and then it is found that the pressure depends on concentration and on the molecular weight, and is directly proportional to the absolute temperature. As already mentioned, Van't Hoff discovered that the osmotic pressure due to a substance is the same as the gaseous pressure which it would exert in the form of gas if it could exist in that form at the same temperature and occupying the same volume as that of the

solution. The gas-constant it has the same value for a substance in solution if p is the osmotic pressure. Quite analogously, knowing the osmotic pressure, volume, and temperature of a solution we can calculate the molecular weight of the dissolved substance. Moreover, the effect of dissolving a substance is to diminish the vapour-pressure of the solvent directly in proportion to the osmotic pressure—that is, inversely as the molecular weight of the substance. The osmotic pressure is difficult to measure; the decrease in vapour-pressure is not. But still easier to measure are changes in the boiling- or freezing-points, and for dilute solutions these are almost exactly proportional to the change in vapour-pressure; hence by an accurate determination of the rise of the boiling-point or depression of the freezing-point, the molecular weight of a dissolved substance can be determined. The method has proved of great value particularly for substances which could not at all or only with difficulty, have been obtained in the gaseous state.

Dissociation.—It was noticed that many substances gave results which did not agree with the known molecular weights. In water, for instance, the effect on the boiling- and freezing-points was much too big, as though their molecular weight was too small. Similar results were known for some gases and had been explained as being due to dissociation of the molecule—e.g. ammonium chloride splitting up into ammonia and hydrogen chloride. A similar theory was introduced to explain the low molecular weights in solutions, but it was further noticed that such solutions were conductors of electricity, the salts were electrolytes, and that there was a very close parallel between the conductivity conferred on the solvent by a given weight of a substance and the osmotic pressure, rise in boiling-point, &c. The theory of electrolytic dissociation harmonises these facts. Thus, when sodium chloride dissolves in water, some of the molecules are supposed to split up into sodium and chlorine ions—i.e. sodium atoms which have lost an electron, and chlorine atoms which have gained one, and the motion of these in opposite directions constitutes the electric current. The more dilute the solution, the more the dissociation; the greater the conductivity for a given weight of substance, the greater the osmotic pressure, &c. Though the results are not absolutely concordant, the agreement is remarkably close. The theory met with considerable opposition at first, but its successful application in almost every branch of chemistry established it firmly as the working hypothesis at the beginning of the 20th century.

The idea of the solvent in producing dissociation is not fully clear, but the most important factor appears to be its specific inductive capacity or dielectric constant. If two charged particles attract each other with a certain force in air, they will attract each other with only half the force in benzene, and only about one-eighth the force in water, the dielectric constants being in the ratio 1:2:80. Probably the water acts, in part at least, by diminishing the electrical attraction between, say, the sodium and chlorine ions in the crystal, so that it passes into solution, and the ions are free to move about. Possibly also there is some kind of combination between the water, or other solvent, and the dissolved substance. One very important law has been discovered and appears to be accurately true for non-aqueous solutions—viz. that the undissociated part is proportional to the cube root of the concentration (i.e. directly proportional to the distance apart of the molecules of the substance) divided by the dielectric constant. Thus, if α is the fraction of the substance which is dissociated, $(1-\alpha)$ is the undissociated portion, v the volume

which contains the molecular weight, D the dielectric constant, then $(1-\alpha)\sqrt[3]{vD} = \text{a constant} = \text{about } 41.5$.

Colloidal Solution.—Graham found that soluble substances could be divided into two classes according to whether they did or did not pass through certain membranes: those which could be called crystalloids, those which could not be called colloids. To the process of separation he gave the name dialysis. As many animal and vegetable substances are colloids, their solutions are of great importance in the chemistry of living matter. In colloidal solutions the particles are not single molecules, but aggregates of, say, 100 molecules, and these have an electric charge, which in the majority of cases is negative, though the hydroxides of the metals have a positive charge. Instead of speaking of the substance as being in solution, it is said to be in the 'dispersed' phase; if this is liquid, the substance is said to be an emulsion; if solid, it is called a suspension. The latter may be coagulated by the addition of an electrolyte to the solution; if they can be readily re-dissolved, they are termed *lyophile*; if not, *lyophobic*. Gelatine is a good example of the former, for the addition of considerable quantities of neutral salts will coagulate the gelatine, but after the removal of the salt it will re-dissolve.

The rate of diffusion of colloids is very slow, the osmotic pressure very slight, the boiling- and freezing-points of their aqueous solutions only slightly different from those of pure water. Under the influence of electrical force the charged colloidal particles move slowly, the phenomenon being called 'cataphoresis.' The particles can be made visible by means of the 'ultra-microscope,' which consists of a horizontal beam of light sent through the solution, so that the light scattered by each particle can be viewed through a powerful microscope above it: bright points of light are seen moving rapidly in all directions. Colloids can be separated by 'ultra-filtration'; for this purpose an ordinary filter paper is soaked in gelatine and then placed in formalin to harden the film; a membrane is thus obtained, which when properly supported will withstand a pressure of several atmospheres; crystalloids will pass through these films, and it is possible to make them of varying permeability, so that under a certain pressure one colloid will pass through, but another not.

Soap solutions, a very important class of colloids, are salts of a weak acid and a strong base, but are only slightly hydrolysed in solution. They can exist either in the form of a fluid 'sol' or a transparent 'gel' or as a white curd.

Thermo-chemistry.—The quantity of heat required to raise one gram of a gas 1° C. (its specific heat) is greater if the gas is allowed to expand than if its volume is kept constant: the difference for a mono-molecular weight is very nearly two calories. If the gas contains only one atom in its molecule, the values for the two molecular heats will be 3 and 5, and their ratio 1:67. For gases containing two or more atoms in the molecule, the molecular heat at constant volume will be greater than 3, for, in addition to raising the temperature, some of the energy is used up inside the molecule: the ratio of the specific heats is then less than 1:67: thus the determination of the ratio gives valuable information as to the constitution of the molecule. By resorting to this method Ramsay found that argon contained only one atom in its molecule; he determined the velocity of sound in the gas, from which the ratio of the specific heats could be calculated.

Dulong and Petit, in the early days of the atomic theory, discovered that the atomic weight \times specific heat was roughly constant, about 6.4, the exceptions being few. It was thus possible to decide the

very important question as to which multiple of the equivalent weight was the atomic weight—viz. that value which when multiplied by the specific heat gave a product near to 6.4. Recent research has shown that close to the absolute zero the specific heat vanishes. As the temperature rises, the specific heat increases as the cube of the temperature, and is a *periodic* function of the atomic weight, like so many other properties of the atom; it is only at higher temperatures that Dulong and Petit's law is correct.

Heat of Formation.—When 12 grams of carbon are burnt to form carbon dioxide, 97,850 calories of heat are produced, and this value is termed the heat of formation of carbon dioxide. When 2 grams of hydrogen are burnt, the heat evolved is 58,300 calories: this is the heat of formation of steam.

In the case of a substance such as benzene, where the heat of formation cannot be directly determined, it can be derived from the above figures together with the known *heat of combustion*. Thus, when 78 grams of benzene are burnt, 777,000 calories are produced; but the combustion of the carbon and hydrogen in the benzene would, if burnt separately, have supplied 760,800 calories. In this case, as the benzene gives more heat than its constituents, it must have been formed with *absorption* of heat, and its heat of formation is $760,800 - 777,000 = -16,200$.

Most chemical changes which take place at the ordinary temperature, which must be regarded as low compared with such temperatures as those of the sun, say 6000°C ., result in the evolution of heat (exothermic). In all such cases, if the change is effected at higher temperatures, the heat evolved will be less, and it is a matter of great importance to know not merely the heat-change at any temperature, but also how this varies as the temperature is changed. Application of the second law of thermodynamics to chemistry enables us to calculate the extent of formation or decomposition of a given compound if we know how the heat of reaction varies with the temperature. The application of this law has led to results of the most far-reaching importance—e.g. the so-called 'phase rule' of Gibbs. The law of mass action (see below) was deduced from the second law by Van't Hoff, who also worked out the relationship existing between the heat evolved in a reaction and the rate of change of the equilibrium constant K (see below)

with change of temperature: $\frac{d \log K}{dT} = \frac{Q}{RT^2}$, from which, knowing the equilibrium constant for two neighbouring temperatures and the heat evolved, Q , at one temperature, T , we can calculate the equilibrium constant over quite a long range of temperature.

The reason for the heat of a reaction being different at different temperatures is that the specific heats of the substances taking part in the reaction are different at different temperatures. It is thus possible, with the help of data for the specific heats, to calculate the extent to which a chemical change will take place at some temperature at which it might be difficult or impossible to experiment. The third law of thermodynamics, which originated as a surmise by Nernst and was confirmed by determinations of specific heats at the lowest temperatures obtainable, is a consequence of the fact that the capacity for the heat of all pure substances vanishes as they approach absolute zero. Knowing this, Nernst has shown how it is possible to calculate in advance from purely thermal data the extent to which any chemical change will take place.

Chemical Statics and Dynamics.—A chemical reaction, which under certain conditions goes in one direction, can frequently be made to go in the opposite direction by altering the conditions: such a

reaction is said to be reversible. Thus, calcium carbonate when heated splits up into calcium oxide and carbon dioxide, but the two latter substances unite on cooling to form calcium carbonate again. If the heating is done at a certain temperature in a closed vessel, the carbon dioxide is given off until its pressure has reached a definite value and the change will appear to have ceased. In reality both the decomposition and the combination are proceeding simultaneously, and a condition of equilibrium has been reached. It is analogous to the equilibrium between a liquid and its saturated vapour. The actual rate of chemical change is often not easy to measure, but the composition of an equilibrium mixture is comparatively easy to determine.

Phase Rule.—In the case of water and aqueous vapour there is a definite equilibrium at a definite temperature, rise of temperature causing evaporation until the pressure of the vapour has reached a new value and a new equilibrium has been established; similarly, in more complicated cases where more than one species of molecule is present, and where solid liquid and gaseous states may all co-exist, equilibrium can be maintained under perfectly definite conditions. The study of such problems is greatly assisted by the help of diagrams such as that given in the figure, which represents the be-

haviour of ammonium chloride and water (simplified by neglecting the aqueous vapour). The line BC may be called the solubility curve for ammonium chloride; the line AB represents the effect of dissolved ammonium chloride in lowering the freezing point of water. If a concentrated solution of ammonium chloride is cooled, the salt will crystallise out until the temperature -16°C is reached, when ice will also crystallise out with it; if a dilute solution is cooled it will be ice that crystallises out, until at -16°C it is joined by crystals of ammonium chloride. The mixture of ice and ammonium chloride crystallising together at -16°C is called the 'eutectic' mixture.

The relationship between the number of phases which can co-exist and the number of chemical substances (components) present under definite conditions of concentration, temperature and pressure, can be expressed in very general form by the 'phase rule' worked out by Gibbs. Denoting the number of phases co-existing by n , the number of components by y , and the number of degrees of freedom by F (i.e. the number of conditions that can be fixed arbitrarily without altering the number of phases), then the rule is that

$$n + 2 = y + F.$$

Resort to the phase rule and phase diagrams has cleared up many difficult problems, such as that of the Stassfurt deposits of crystalline minerals, and has in very recent times led to important advances in chemical manufactures.

Law of Mass Action.—The fundamental law that the rate of a chemical change is proportional to the active mass or concentration of the reacting substances was first fully grasped by Guldberg and Waage, and elaborated in a book published in 1867. If one substance, A, unites with another, B, to produce a third, AB, and if their concentrations are a , b , and c respectively, then the rate of formation of AB is proportional to both a and b , and we may write: velocity of formation $= ab.k$, where k is the 'velocity constant.' Similarly, the velocity of the reverse action $= k'.c$.

When equilibrium has been reached the two rates will be equal, and we have $k.ab = k'.c$, or, $\frac{k}{k'} = \frac{c}{ab}$; we write $\frac{k}{k'} = K$, and call it the 'equilibrium constant': it has been referred to already. The law of mass action is applicable to the whole field of chemistry. A few instances will be given.

(a) *Gases*.—At ordinary temperatures the formation of hydrogen iodide from iodine and hydrogen is too slow to be measurable; at 250° C. it would take months to reach equilibrium, at 350° C. it would take days, but at 450° C. only hours; reaction velocity always increases with rise of temperature, also with increase of pressure. No matter whether we start with the hydrogen and iodine or with the hydrogen iodide, the composition of the mixture will be the same when equilibrium is reached, and the pressure in this case will not affect the composition, as the number of molecules does not change during the reaction. (b) *Liquids*.

—Here the most familiar example is the action of ethyl alcohol on acetic acid, forming ethyl acetate and water; the rate of formation can conveniently be measured by titrating the acetic acid remaining uncombined as the action proceeds. If equivalent quantities of alcohol and acid are taken, equilibrium is reached when two-thirds of each has been transformed. (c) *Solutions of Electrolytes*.—When, for example, acetic acid dissolves in water, it is partially ionised into hydrogen ions and acetions, and these tend to re-unite. Equilibrium will be established when the rate of dissociation equals the rate of re-combination. In a normal solution this is the case when about 4 per cent. of the acid is dissociated.

Ostwald's Dilution Law.—If c denotes the concentration of the undissociated acid, and c_1 that of either of the ions, then the equilibrium constant $K = \frac{c_1^2}{c}$. If we denote the fraction of the acid dissociated by α , the remainder will be $1 - \alpha$, and if v litres contain one gram-molecule of electrolyte

$$C = \frac{1-\alpha}{v}, \quad c_1 = \frac{\alpha}{v}, \quad \text{and } K = \left(\frac{\alpha^2}{v} \cdot \frac{v}{1-\alpha} \right) = \frac{\alpha^2}{(1-\alpha)v}.$$

This dilution formula has been found satisfactory for a very large number of substances in dilute solution, but it is incorrect for 'strong,' i.e. highly ionised, electrolytes. As the strength of an acid depends on the number of H⁺ ions it sends into the solution, we can compare the strengths of acids by comparing their equilibrium constants: thus, K for acetic acid is 0.000018, whereas for trichloroacetic, which is much stronger, K is 0.00155.

The effect of adding hydrochloric acid to a solution of acetic acid is to reduce the dissociation still further, for, with the increased number of H⁺ ions present, the undissociated acetic acid can no longer maintain the equilibrium, and some of its ions will associate. Similarly, if sodium acetate were added, the increase in the number of acetions

would cause some of those present to associate with the hydrogen ions, and the solution would become less acid. This method of adding a common ion has many important applications.

Neutrality.—Several lines of investigation show that water is itself dissociated into hydrogen and hydroxyl ions; at the ordinary temperature the ionic concentration of these is about 1×10^{-7} , i.e. a litre of water will contain about 1 ten-millionth of a gram of hydron and 17 ten-millionths of a gram of hydroxidion. This actual concentration is minute, but it plays a very important rôle in the explanation of many chemical facts.

As H⁺ is the characteristic ion furnished by acids, and OH⁻ is the ion typical of bases, when their concentrations are equal the solution is 'neutral.' Assuming a normal solution of a strong acid to be completely ionised, such a solution will contain one gram of H⁺ ions per litre, and the OH⁻ ions will be reduced to 17×10^{-14} of a gram. In a normal solution of, say, sodium hydroxide there will be 17 grams per litre of OH⁻ ions and 1×10^{-14} of a gram of H⁺. The neutralisation of an acid by a base is essentially the combination of these ions to form water. This is shown by the ionic equation:

This explains the fact that the heat of neutralisation of all strong acids by strong bases is the same—viz. 37,400 calories per equivalent weight: it is the heat of association of water.

Hydrolysis.—The ionisation of water produces its most notable effect in solutions of substances which are themselves only slightly ionised, such as weak acids and bases and their salts. In such cases the H⁺ and OH⁻ ions produce a marked effect in the final equilibrium. Thus potassium cyanide in solution is 'hydrolysed' to about 1 per cent., due to the acid being a very weak one:

This accounts for its alkaline reaction and its smell of prussic acid. Similarly, sodium carbonate, the salt of the very weak carbonic acid, is hydrolysed and has an alkaline reaction. On the other hand, aluminium chloride and aniline hydrochloride are examples of weak bases whose salts consequently give an acid reaction.

Indicators.—Many substances are known which possess a different colour according as they are in an acid or an alkaline solution; their sensitiveness depends upon the concentration of the H⁺ or OH⁻ ions, at which the change in colour takes place. It is possible to choose an indicator so that the colour change occurs sharply at the point desired.

Chemical Kinetics.—The actual rate of chemical change was measured very simply in 1850 by Willhielmy in the case of the inversion of cane-sugar:

A solution of cane-sugar rotates the plane of polarised light to the right, but when allowed to stand in the presence of acids it slowly combines with water, splitting up into dextrose and levulose, the solution of which rotates the plane to the left. The rate of change can be timed by watching the solution through a polarimeter. It is found that the rate at any time is proportional to the concentration of the cane-sugar. As the rate also depends on the degree of dissociation of the acid, this method can be used for comparing the relative strengths of different acids. As in the above case, when the change in the solution results from the change of only one species of molecule, the reaction is said to be 'monomolecular.' Another somewhat similar example is the addition of water to methyl acetate resulting in the formation of methyl alcohol and acetic acid. In this case the

action can be followed by titrating the acid from time to time. The reaction proceeds more rapidly in the presence of a little acid.

Bi-molecular Reactions.—In the previous case, if an alkali is used instead of an acid, hydrolysis takes place, but its rate at any moment depends not only on the amount of ester left in the solution, but also on the amount of alkali, i.e. the hydroxyl ions, and both of these are changing simultaneously $\text{CH}_3\text{COOCH}_3 + \text{K}^+ + \text{OH}^- = \text{CH}_3\text{OH} + \text{K}^+ + \text{CH}_3\text{COO}^-$. The rate can be measured by titrating with acid at intervals as the action proceeds.

Catalysis.—The rate of a chemical change is often found to be greatly influenced by the presence of small quantities of certain substances which do not themselves suffer any final change. Such substances were called by Berzelius 'catalysts.' The phenomenon of catalysis covers a very wide range, for there are many different kinds of catalysts. Some may be compared with lubricants which facilitate the operation of machinery without being part of it; others to middlemen whose function is to acquire and then to re-distribute; in other cases they act like a siphon connecting a mountain lake over a ridge to a power-station below: if once the initial energy can be supplied to raise the water to the top of the siphon, then the energy in the lake becomes available, say, for driving turbines. Among the most familiar examples are the use of finely-divided platinum in promoting the combination of hydrogen and oxygen to form water, and of SO_2 and oxygen to form SO_3 , the use of acids and bases in hydrolysis, as described above, the necessity of traces of moisture as in the case of phosphorus burning in oxygen, recent important applications such as the synthetic manufacture of ammonia from nitrogen and hydrogen in the presence of certain metals, and the hydrogenation of liquid fats in the presence of nickel rendering them suitable substitutes for butter. The action of light may also be regarded as catalytic in producing certain photo-chemical changes.

Electro-chemistry.—The quantitative foundations of electro-chemistry were laid by Faraday in 1833. He discovered that when an electric current is passed through a solution of an electrolyte the amount of decomposition is proportional to the amount of electricity which passes through, and that the amount of each substance produced is proportional to its equivalent weight, one equivalent of each element requiring 96,540 coulombs (ampere-seconds). This quantity is now known as a 'faraday.'

Conduction.—We picture the electric current in a metallic conductor as being carried by swarms of electrons capable of moving with great speed: when these arrive at the surface of an electrolyte they attach themselves to the positive ions, which have been attracted to that electrode, and neutralise them: the anions carrying their negative charge are attracted to the anode, where they lose an electron and are neutralised. The resistance of electrolytes is in accordance with Ohm's law, and is measured in much the same way as for metallic conductors, except that an alternating current must be used to avoid effects due to 'polarisation,' and a telephone is often used in place of a galvanometer. As the conductivity depends on the number of ions present in the solution, Arrhenius perceived that it should be possible to calculate the degree of dissociation by comparing the molecular conductivity at different dilutions. Thus, if the molecular conductivity at dilution v is denoted by λ_v , and at very high dilution by λ_∞ when the dissociation may be regarded as complete, then the degree of dissociation at dilution v will be $\frac{\lambda_v}{\lambda_\infty}$. This

method has been extensively used for determining degree of dissociation.

Transport Numbers.—The solvent offers greater resistance to the passage of some ions than to that of others—e.g. hydrogen ions can travel most rapidly of all. In certain cases it is possible to measure the actual velocity: for hydrogen the speed is about 1 cm. in five minutes under a force of one volt per centimetre. The relative velocity, however, is easily determined as a result of the difference in concentration caused at the electrodes during electrolysis owing to the different rates of the two ions. This was first perceived by Hittorf in 1853. If u is the velocity of the kation and v that of the anion, the total current passing will be proportional to $u + v$, but $\frac{u}{u + v}$ will represent the fraction of the current carried by the migration of the kations and $\frac{v}{u + v}$ the fraction carried by the anions. Equivalent quantities must be *liberated* at the electrodes, but from the change in the composition of the solution round the electrodes the ratio $\frac{u}{v}$ can be calculated.

Electromotive Force.—When a metal is placed in a solution of one of its salts it tends to send out into the solution positively charged ions of the metal. The solution acquires a positive charge and the metal a negative one. The attraction of the charged metal holds the ions in a layer round it. This tendency, called by Nernst the solution pressure of the metal, is different in degree for each metal, and can be determined by the difference of potential between the metal and a normal solution of one of its salts. Placed in order according to the magnitude of this force, the elements form an electromotive series with the alkali metals at the positive end and the halogens at the other. If we have zinc dipping into zinc sulphate and copper into copper sulphate, the liquids being separated by a porous plate, then, on connecting the zinc and copper by a wire, electrons will flow along the wire from the zinc to the copper, and a voltmeter placed in the circuit will indicate about 1.1 volts. The explanation of this is found in the greater tendency of the zinc to send out positive ions into the solution. As soon as the circuit is completed the negative electrons move along the wires from the zinc to the copper, and the positive ions are no longer held in a layer closely attracted to the electrode, and can move through the liquid to the copper. It is probably this difference between the power of the zinc and copper to send out positive ions that constitutes the electromotive force of the arrangement. This simple form of primary battery is known as a Daniell's cell.

On the assumption that all the chemical energy is converted into electrical energy, the electromotive force can be calculated from the heats of formation of zinc and copper sulphate, and agrees closely with the value found experimentally; the slight divergence being accounted for by the fact of great theoretical importance that there is a slight variation of the force with temperature.

Decomposition Potential.—If a very small voltage is applied to a solution of an electrolyte, no decomposition takes place. If the voltage is then slowly increased a point will be reached at which decomposition just begins. This potential is the sum of the potentials required to discharge both the anion and the kation. The value can be found for each ion, and thus it is possible to calculate the minimum voltage that will be required to effect the decomposition of any combination.

Photo-chemistry.—It has been known for more than a hundred years that a mixture of equal

volumes of hydrogen and chlorine when exposed to light will combine with explosive violence; many other cases of photo-chemical change have been studied, both formation and decomposition, and the whole art of photography has resulted from the pursuit of the study in one direction, including the latest branch of colour-photography. The advent of the electrical theory of the atom, and the theory of radiation which followed immediately, culminated in Einstein's simple law of photo-chemical equivalence that the primary photo-chemical change is produced by the absorption of one light quantum by one molecule. The simple conditions which are necessary for the fulfilment of this law are seldom realised, for the energy gained by the molecules is quickly shared on collision with other molecules, or radiated again, and many qualifications have to be introduced. Nevertheless, the conception of the atoms and molecules as planetary electrical systems existing in normal states with fundamental periodic vibrations, which can be raised to definite states of higher activity by the absorption of radiant energy of definite wave-length, has given great stimulus to the study of the effect of radiation on the velocity of chemical reactions. Not only so; the increase of velocity which is caused by increase of temperature is quite inexplicable on the assumption that it is simply due to increase in the average energy of the molecules caused by increased thermal agitation. There are those who maintain that the rate of chemical change is determined not by thermal agitation but by the power the molecules possess of absorbing certain specific radiations. The problem is one of fundamental importance, and at present remains open.

Authors of books recommended on physical chemistry: Introductory, Sir James Walker; more advanced, Nernst, Eucken, H. S. Taylor, W. C. McC. Lewis, Perrin, *Atoms* (trans. by Hammett).

Physicians, THE ROYAL COLLEGE OF (London), was founded by the munificence of Thomas Linacre (q.v.), a physician and scholar. In 1518, through the influence of Cardinal Wolsey, he obtained from Henry VIII. letters-patent granting to John Chamber, himself, and Fernandez de Victoria, the acknowledged physicians to the king, together with Nicholas Halsewell, Giovanni Franceschi, Robert Yaxley, and all other men of the same faculty in London, to be incorporated as one body and perpetual community or college. They were permitted to hold assemblies, and to make statutes and ordinances for the government and correction of the College, and of all who exercised the same faculty in London and within 7 miles thereof, with an interdiction from practice to any individual unless previously licensed by the president and College. Linacre was the first president, and held the office till his death in 1524. The meetings of the College were held at his house in Knight-rider Street, which he bequeathed to the College, and which until the year 1860 continued in the possession of that body. About the time of the accession of Charles I. the College, requiring more accommodation, took a house at the bottom of Amen Corner, which was subsequently purchased by Dr Baldwin Hanbury, and in 1649 was given by him to his colleagues. This was the seat of the College till 1686, when it was destroyed by the great fire of London. A new College was then built in Warwick Lane, and opened in 1674 under the presidency of Harvey's friend, Sir George Ent; and here the meetings were held till 1825, when the present edifice in Pall Mall East was opened under the presidency of Sir Henry Hallford.

The reason for forming the incorporation, as set forth in the original charter, is to check men who profess physic rather from avarice than in good

faith, to the damage of credulous people; and the king (following the example of other nations) founds a college of the learned men who practise physic in London and within 7 miles, in the hope that the ignorant and rash practisers be restrained or punished. The charter further declares that no one shall exercise the faculty of physic in the said city, or within 7 miles, without the College license, under a penalty of £5; that, in addition to the president, four censors be elected annually to have correction of physicians in London and 7 miles' circuit, and of their medicines, and to punish by fine and imprisonment; and that the president and College be exempt from keeping watch and ward and serving as constable in the city of London. Four years later, 1522-23, an act was passed confirming the charter, and enacting that the six persons before said named as principals and first named of the said commonalty and fellowship shall choose to their two men of the said commonalty from henceforward to be called and elected Elects, and that the same elects yearly choose one of them to be president of the said commonalty; and further directing that, in case of a vacancy by death or otherwise, the surviving elects shall choose successors.

In 1540 an act was passed in which it was declared explicitly that 'surgery is a part of physic, and may be practised by any of the company or fellowship of physicians'—a doctrine which in later times has been totally repudiated by the collegiate body, who, until recently, would not admit to their privileges a member of the Royal College of Surgeons unless he formally resigned his surgical diploma. Other acts were passed in 1553, 1814, and 1858; the last known as the 'Medical Act,' providing for the granting of a new charter to the College, which was obtained in 1862. Finally, in 1860, 'an Act to Amend the Medical Act' was passed, which repeals the provisions of the Act of 1522-23 as to the elects, and declares that the presidency shall in future be an annual office, open to the Fellows at large, who shall also be the electing body. As at present constituted, the College consists of Fellows, Members, and Licentiates (some 370 Fellows, 700 Members, and 16,000 Licentiates). The *Fellows* are elected from members of at least four years' standing, who have distinguished themselves in the practice of medicine, or in the pursuit of medical or general science or literature. The government of the College is vested in the president and Fellows only. The present *Members* consist of persons who have attained the age of twenty-five years, and who, with rare exceptions, must be graduates in medicine of a recognised university or licentiates of the College, who do not dispense or supply medicine, and who, after being duly proposed, have satisfied the College that they are fit and proper persons, and that their general education is sufficient. No candidate is admissible if engaged in trade or connected with a druggist's business, or who even practises medicine in partnership with another practitioner, so long as the partnership lasts, or who refuses to publish, when required, the nature and composition of any remedy he makes use of. The *members* are alone eligible for the Fellowship. They have the use of the library and museum and the privilege of admission to all lectures; but they do not take any share in the government or attend or vote at meetings. The examiners for the membership are the president and censors. The *Licentiates* are not members of the corporation; they have access to the museum, lectures, and reading-room, but are not allowed to take books away from the library; they may compound and dispense medicines for *patients under their own care*. Following upon the Medical Act

of 1886, the Colleges of Physicians and Surgeons combine to give a 'double qualification' entitling the holder to practise both medicine and surgery. Holders must be twenty-one years of age, and must have been engaged in professional studies for five years before being admitted to examination. The fee for admission as a Fellow is thirty-eight pounds, exclusive of stamp-duty: the Member's fee is also forty guineas, and the Licentiate's twenty guineas.

The following bylaws of the College should be generally known: (1) No Fellow of the College is entitled to sue for professional aid rendered by him. This bylaw does not extend to Members. (2) No Fellow, Member, or Licentiate of the College is entitled to assume the title of Doctor of Medicine unless he be a graduate in medicine of a university. (3) No Fellow or Member of the College shall officiously, or under colour of a benevolent purpose, offer medical aid to, or prescribe for, any patient whom he knows to be under the care of another legally qualified medical practitioner.

THE ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH had its inception in 1617, in an attempt to incorporate the practitioners of medicine, and raise the standard of the profession. King James I. of England looked favourably on the proposal, and granted an order for its establishment. King Charles I. also gave the matter his attention and referred it to the Privy-council, and Cromwell in like manner issued a patent in its favour; all these attempts, however, were frustrated by the religious and political dissensions of the times, and it was not until 1681 that the body became incorporated under a charter from Charles II. A new charter with many important provisions was issued in 1861. To the Physicians belongs the honour of having suggested in 1725 the plan of an infirmary in Edinburgh for the sick poor, which has developed into the present magnificent institution. From the first they undertook its medical charge gratuitously. The Royal Edinburgh Asylum for the Insane at Morningside was also first suggested by them in 1791. The College, which in 1926 had over 200 Fellows, possesses a library of about 100,000 volumes, a valuable and interesting museum of materia medica, which is in the keeping of the Pharmaceutical Society at York Place, Edinburgh, and a splendidly equipped laboratory for the purpose of aiding the prosecution of scientific research. An important arrangement was made in 1859 between this college and the Royal College of Surgeons (q.v.) of Edinburgh, making it competent for the two to combine, in order, by a joint examination, to give a double qualification, embracing medicine and surgery. In 1884 a further consolidation of the Scottish medical corporations took place, by the institution of a triple qualification, granted by the Edinburgh colleges and the Royal Faculty of Physicians and Surgeons of Glasgow conjointly. This 'triple qualification' is held by some 4000 medical practitioners.

Physic Nut, a name for certain plants of the genus *Jatropha* (family, Euphorbiaceæ), tropical shrubs or trees, having alternate, stalked, angled or lobed leaves, and corymbs of flowers on long stalks. The Common Physic Nut of the East Indies (*J. Curcas*), now also common in the West Indies and other warm parts of the world, is a small tree or bush, with a milky juice. It is used for fences in many tropical countries, and serves the purpose well, being much branched and of rapid growth. The seeds are not unpleasant to the taste, but abound in a very acrid fixed oil, which makes them powerfully emetic and purgative, or in large doses poisonous. The expressed oil, commonly called *Jatropha-oil*, is used in medicine like croton-oil, although less powerful; it is also used in lamps.

Other species are *J. multifida* and *J. lobata*. *J. longifolia* is got in San Salvador.

Physics, or PHYSICAL SCIENCE (Gr. *physikos*, 'natural'), comprehends in its widest sense all that is classed under the various branches of mixed or applied mathematics, natural philosophy, chemistry, and natural history, which branches include the whole of our knowledge regarding the material universe. In its narrower sense it is equivalent to Natural Philosophy, which until of late years was the term more commonly used in Great Britain, and denotes all knowledge of the properties of bodies as bodies, or the science of phenomena unaccompanied by essential change in the objects; while chemistry is concerned with the composition of bodies, and the phenomena accompanied by essential change in the objects, and natural history, in its widest sense, includes all the phenomena of the animal, vegetable, and mineral world. The use (now obsolescent) of the term *Physic* for a branch of this last—viz. the science of medicine—is not peculiar to the English language. The Old French usage recognised *physique* in the sense of medicine; while almost all languages have used some form of the word *physician* for a practitioner of the art. See SCIENCE.

Physiocratic School, a school of political economists in France headed by Quesnay and Gournay, who, in opposition to the Mercantile System (q.v.), regarded agriculture as the great source of national well-being, and sought to regulate legislation accordingly. Turgot (q.v.) was the most conspicuous member. See POLITICAL ECONOMY.

Physiognomy (from a Latin shortened form of the Gr. *physiognomônê*), the art of judging of the character from the external appearance, especially from the countenance. The art is founded upon the belief, which has long and generally prevailed, that there is an intimate connection between the features and expression of the face and the qualities and habits of the mind; and every man is conscious of instinctively drawing conclusions in this way for himself with more or less confidence, and of acting upon them to a certain extent in the affairs of life. Yet the attempt to reach this conclusion by the application of certain rules, and thus to raise the art of reading the human countenance to the dignity of a science, although often made, has never yet been very successful. Comparisons were instituted for this purpose between the physiognomies of human beings and of species of animals noted for the possession of peculiar qualities, as the wolf, the fox, &c. The subject was prosecuted by Della Porta (died 1615), Campanella, Cardan, Ingenieri, and especially by Lavater (q.v.). Darwin's *Expression of the Emotions in Man and Animals* (1873) is regarded as the first attempt to base a rational physiognomic system on a basis of modern scientific research; Mantegazza, in *Physiognomy and Expression* (Contemp. Sc. Series, 1890), claims to have begun where Darwin left off. Piderit, in *Mimik und Physiognomik* (2d ed. 1886), proceeds on the obvious fact that the most valuable data are not to be derived from the bony framework of the countenance, but in the mobile parts which express emotion; features which constantly express the same emotion come to be stamped with permanent physiognomic characters. Pathological physiognomy is a systematised effort to diagnose mental or bodily ailments by examination of the varying facial expression. Another practical application of physiognomic study is found in what has been called Criminology. See works named in the article under that head.

Physiography, a term formerly used of a branch of mineralogy, was adopted by Professor

Huxley as a convenient name for an exposition of the principles that underlie physical geography, including the elements of physical science. Physiography is thus understood to involve a compendious discussion of gravitation, heat, the composition of the crust of the earth, the movements of the sea, the phenomena of the atmosphere, and many cognate subjects, treated in this work under separate heads. See GEOGRAPHY.

Physiologus. See BESTIARY.

Physiology (Gr. *physis* and *logos*, 'discourse upon nature') is the science which treats of the behaviour of living beings, and of the functions of their parts. It is thus the sister-science to Morphology (q.v.), in which the form of living creatures and the structure and arrangement of their parts are considered. Both are included under the more general term Biology (q.v.). A peculiar use of the term *physis* is due to Hippocrates, who applied it to a spiritual entity which he supposed to be everywhere present, and to keep the processes of the body in order. This use of the word is still kept alive in oft-repeated phrases, as when in speaking of a sick person it is recommended that the cure be left to nature. There is an Animal Physiology, of which this article will mainly treat, and a Vegetable Physiology (q.v.); also a Comparative Physiology, which, however, is still imperfect, for the details of the life-processes have not been investigated in all animals, and our knowledge is most defective in those belonging to the invertebrate groups. In many cases, comparative physiology consists of inferences from morphological data, and such inferences are often erroneous. On the other hand our knowledge of human physiology rests to a great extent upon experimental data derived from the lower animals. Physiological processes, however, are fundamentally the same throughout the animal kingdom. Such differences as are present are differences in detail or degree rather than of kind. Still the animals closely related to man are obviously those which give the most decisive results from the human standpoint. Human physiology used to be termed the Institutes of Medicine, an expression which still prevails in some of the Scottish universities, and which has the merit of indicating that physiology is the corner-stone of pathological and medical science.

But physiology has a wider outlook than this. For as all the organs of the body are mutually related, so that if one is deranged all the others will be more or less affected, so are there close relationships between the various creatures of the globe. Thus, to quote Seemper, *Animal Life* (1881): 'If the American prairies were to cease to produce grass, the first result would be the utter extinction of the now numerous herds of buffaloes, and on their existence depends that of the surviving remnant of the ancient Indian population of America. If the various insectivorous birds of North America were exterminated, within a very few years beyond a doubt all the produce of the rich agricultural districts of that continent would be destroyed. If we change the mode of life of any single animal, the change will instantly have an influence on all the other animals whose healthy existence was in any way dependent on its normal function before it was altered.' The most obvious relation of this sort is that which exists between plants and animals; similar ones hold good for human beings in their relationship to other living things, and to each other. Thus Political Economy, the science which treats of the laws of human activities, may from this point of view be regarded as a department of the science of physiology. It is customary to speak of such a wide aspect of physiological science as General Physiology. A

well-known text-book by Max Verworn (*Allgemeine Physiologie*) was one of the first to emphasise this point of view, and in the monumental work of the late Sir William Bayliss (*Principles of General Physiology*, 2d edition 1924), the aims of General Physiology are thus defined in his preface:—It is "Abstract" Physiology as distinct from the "Applied" Physiology required by the agricultural, medical, or veterinary student for the purpose of his profession. The name of "General" Physiology which I have chosen corresponds very closely with what my honoured teacher, Burdon-Sanderson, used to speak of as "Elementary" physiology, defining it as "the study of the endowments of living material" from which he expected the greatest advances of the future to proceed. This is practically the same view as that taken by the great Claude Bernard, who was professor of "physiologie générale" in Paris from 1854 until he died in 1878. In the lectures which he gave he insisted on the fact that physiology, the science of life, is to be regarded as an autonomous and independent study; in other words, that it is to be cultivated for its own sake, and not merely for its application to the practice of medicine.'

In such endeavours Bayliss, like his predecessors, brought to bear upon the science his deep knowledge of all other branches of biology as well as of chemistry and physics. This is, indeed, the aim of all physiological workers and thinkers, but as a rule the subject is so large that specialisation is the consequence. Some devote their main attention to certain groups of phenomena such as one finds in the nervous system, others to certain modes of investigation as in the large branch which used to be called physiological chemistry, but which has now received the wider title of bio-chemistry. If Bayliss had any special bent it was in the direction of physical chemistry with its mathematical side, and the way such a study of ions, colloids, and the like can be called into service in the investigation of living phenomena.

Knowledge of the bodily functions has been gained in three ways: (1) by observing the normal states of living things; (2) by experiments upon these; (3) by studying the processes of disease. No science can advance rapidly or with certainty without experiment, and most of our precise knowledge of physiology has been gained in this way, from the time when Galen proved that the arteries during life contain blood, or when Harvey demonstrated the circulation of that blood.

Diseases are in a sense experiments made by nature or accident. As an example of how they teach us something of normal functions, we may note the recent progress of knowledge concerning the uses of the formerly mysterious organs now termed the endocrine organs such as the thyroid, pituitary, and suprarenal bodies. When these become hyperactive, their normal function is exaggerated; or when they atrophy the malady produced shows the opposite symptoms.

The functions of the body of the lowest up to the highest types consist essentially of the properties of the living material known as Protoplasm (q.v.). The principal signs of life are: (1) *Irritability*, that is, the property of responding by some change under the influence of an external agent or stimulus; the most obvious of these changes is *movement* (e.g. amoeboid movement, ciliary movement, muscular movement); (2) *Assimilation*, that is, the ability to convert into protoplasm the nutrient material or food which is ingested; (3) *Growth and repair*: this is the consequence of assimilation; (4) *Reproduction* (q.v.), which may be regarded as a variety of growth; (5) The power to *excrete*, or to give out waste materials which are produced in all vital activities.

Of all these signs those numbered (2) and (5) are the most essential. Living material is in a continual state of unstable chemical equilibrium, building itself up on the one hand, breaking down on the other; the term used for the sum total of these intra-molecular rearrangements is *Metabolism*, the building up or assimilative phase being called *Anabolism*, whereas the opposite or disintegrative phase is known as *Katabolism*. The chemical substances in the protoplasm which are the most important from this point of view are the complex nitrogenous compounds known as the *Proteins* or albuminous substances. So far as is at present known, protein material is never absent from living substance, and is never present in anything else but that which is alive, or has been alive, or formed by the agency of living cells. Recent research indicates that there are certain fat-like substances called *lipoids*, which, although present in minute quantities, share with the proteins their characteristic and essential metabolic behaviour.

Metabolism (German *Stoffwechsel*, or exchange of material), or in more familiar language, nutrition, includes all those processes concerned in the supply of matter and energy to the body and the removal of waste materials. The word food should include not only the solids and liquids, but also the intake of oxygen (Respiration, q.v.); the entry of food is followed by its Digestion (q.v.), the Absorption of the digested food into the Blood (q.v.) and Lymph (q.v.). The movement (circulation) of these fluids ensues, and this insures that all the tissues are bathed in a nutrient stream, and by the same mechanism waste matters are removed from them (Excretion).

Movements are in the main performed by the contraction of muscles definitely arranged especially with relation to the skeletal or supporting structure.

In process of evolution a special portion of the body becomes modified to act as the co-ordinator of all its other processes; this is the Nervous System, which becomes more complex as we ascend the animal scale. It consists of the Central Nervous System (Brain and Spinal Cord), and the nerves by which these headquarters convey messages (nerve impulses) to motor and other effector organs (e.g. secreting glands), and receive impulses which course in the opposite direction, giving the brain information to guide it in the sending out of appropriate outgoing motor and similar impulses; the incoming sensory impulses start in the periphery of the body from the sense organs. These consist chiefly of the eyes, ears, the olfactory region of the nose, the gustatory region of the tongue, and the skin generally, where the impulses reaching the brain are interpreted as sensations of touch, temperature, and pain. The brain is the 'organ of mind,' and the highest faculties of consciousness and initiation have their seat in that portion termed the cerebrum.

The various functions of the body thus briefly enumerated are dealt with in separate articles, but here we may deal with some considerations of general importance.

The first of these topics may be introduced by considering the life of the simplest animals. Almost invisible to unaided sight, flourishing in the stagnant water of ponds, without separate organs, they are little more than tiny masses of the jelly-like substance called Protoplasm (q.v.). Their life seems to consist in movement, nutrition, growth, and reproduction; whether they possess the elements of consciousness we can only dimly conjecture; a nervous system is certainly absent. For movement a source of energy is required; this is found in their food—minute organisms, and organic particles dissolved in the water in which they live. These consist of substances of high

potential energy. They are either plants which are able to utilise the energy of the sun for their growth, or remains of plants or animals which have fed upon plants. See PHYSIOLOGY (VEGETABLE). Thus we see in animal protoplasm a machine for the transformation of potential energy into other forms of energy, such as the energy of motion, heat, and electrical disturbances. This machinery is constantly breaking down and being repaired, the protoplasmic matter is continually being replaced by new matter similarly combined. But, as the protoplasm is extremely complex, the simpler substances of the food have to be combined and recombined in a series of stages of increasing complexity until the complex living matter itself is formed. These combinations are due to certain subtle agents known as ferments or enzymes (see later) in the protoplasm. This power it is which makes growth possible—i.e. the actual increase in amount of protoplasm. The growth of a crystal out of its solution is a process of simpler nature and may seemingly be endless, but growth of a cell never proceeds beyond a certain point, when the process known as Cell-division occurs. The mass of protoplasm divides into two halves, and each half goes on living as before. The necessity for cell-division arises partly from the conditions of the food supply. Food is absorbed through the surface of the cell, but with growth the mass to be fed increases faster than surface; therefore starvation must occur at a certain stage of growth unless the cell divides. The higher animals are built up of numberless cells (see CELL) which have all arisen, by division, from a single cell, the ovum; but instead of becoming separated they have all kept together, joined probably by strands of protoplasm. The cells are massed into tissues and the tissues into organs, the organs having special functions. This difference in the behaviour of the cells of different parts of the body is an example of Division of Labour (q.v.). We can form some idea of its origin. Imagine a cell to divide many times, but the daughter-cells to remain loosely joined together; the outer and inner cells would live under different conditions and would assume different functions. The whole story of the evolution of life, both in the origin of individual forms and in the growth of nations, is simply the process of the division and organisation of labour. For just as an organism is a collection of cells, each having its own life, yet all bound together for mutual service, so is a nation a collection of individual men and women. And as the perfection of an animal is measured by the completeness of the division of labour among its cells, so is the civilisation of a nation measured by the harmony of organisation of its labour. Further, just as there have been many species of animals which have appeared, lived for a time, and then given place to higher species, so there have been civilisations which have flourished for a time and then died away. Any fairly complex civilisation will serve as a type of the division of labour in the body of one of the higher animals. First there are the parts concerned in the getting of food, like the limbs and mouth of an animal. Then the food is prepared for use by other labourers; such are the digestive organs of the animal. The food has to be distributed to all members of the community by merchants and carriers; the blood and the blood-vessels perform this function. The whole community has to be warned of dangers, directed and governed, and made to act harmoniously by the statesmen of a nation; the same things are done by the sense organs, brain, and nervous system of an animal.

We have already noted that the source of energy of an animal lies in its food. The accurate

calorimetric work of Rubner in Germany and of Benedict in America has shown that the law of conservation of energy is true in animal life, that is, that the potential energy of the food is exactly equal to that dissipated as heat, kinetic energy, &c., during life; the results of the earlier work of Lavoisier and others, which indicated discrepancies between intake and output, were due to the imperfection of their instruments. The food is either (1) burned in the tissues as fuel for the protoplasmic machinery, or (2) used to keep that machinery in repair. This twofold aspect of the use of food was clearly recognised by Liebig, who spoke of the fats and carbohydrates (sugar and starch) as heat-forming foods and of the nitrogenous materials or proteins as flesh-forming. This distinction between the heat or energy-forming materials and those essential for growth and repair is not quite so closely limited to the non-nitrogenous and nitrogenous components respectively as Liebig asserted, but is nevertheless in the main correct.

In all cases, however, the food-stuffs have to be prepared (digested) before utilisation. This renders them soluble and diffusible, the heavy molecules of such substances as starch and protein being broken up into smaller molecules of the sugar called glucose and amino-acids respectively. These products are absorbed into the blood-stream. The third class of food-stuff (the fats) after a preliminary cleavage into glycerine and fatty acids pass in large measure into another set of absorbent vessels, the lymphatics or lacteals, the latter name being given because during absorption they are filled with an emulsion of finely divided fat (chyle), which has a milky appearance. These effects are produced by the various digestive juices (saliva, gastric, pancreatic, intestinal juice, &c.).

The blood so charged with absorbed food substances passes to the liver, a large organ, which is concerned with carbohydrate and protein metabolism; the sugar is stored as glycogen or animal starch, and given out again as sugar as the other tissues require it. The muscular tissue is the great consumer of sugar, and it is to the cells what coal is to the steam-engine. The liver also forms one of the digestive juices called Bile (q.v.); the importance of the liver in the katabolism of the proteins will be indicated in a later paragraph.

There is, however, a most important food-stuff which requires no digestion. This is oxygen, which is needed by the protoplasm for its life, and for the burning of fuel within the living machinery to get heat and energy of motion. The oxygen is held in the Blood (q.v.) by means of a special iron-containing substance called haemoglobin, which absorbs it from the air in the lungs, and yet gives it up readily to the protoplasm of the tissues. The blood, as is well known, circulates round and round the body, pumped by the heart. By this stream each cell of the tissues is fed. For each cell is close to a capillary, which is a very thin-walled blood-vessel, through which the fluid of the blood oozes, and thus bathes the tissues. The matter which has thus passed out of the blood-vessels is collected into another system of vessels, the lymphatics, and eventually emptied into one of the great veins. The lymph stream is also the drain into which is thrown by each cell the waste products of its activity. The carbonic acid that is formed in the tissues is carried away by the blood, and escapes out of the system from the lungs, or, in aquatic animals, by the gills, which play the same part. The waste materials are chiefly products of oxidation, and of these carbonic acid is the most abundant; but hydrogen, sulphur, phosphorus, and other elements are also oxidised, forming water, sulphates, phosphates, &c., respec-

tively, and these are excreted mainly by the kidneys, although the sweat-glands of the skin participate in their excretion. Some of the water is also exhaled in the expired air by the lungs. This leaves us to deal with the nitrogenous waste; and here, as already indicated, the liver has important work to do. We take our nitrogen not in the simple form abundantly present in the atmosphere, but in the shape of the most complicated compounds known to chemists, which they call proteins; after undergoing cleavage into simpler materials, the products of cleavage pass to the tissues where they are utilised for growth and repair, but by far the greater bulk is worked up into the special material called urea by the liver, whence it is taken to the kidney by the blood, and cast out of the body by the kidneys; urea forms the chief solid substance dissolved in the urine. Other waste nitrogenous matter in the shape of uric acid and other katabolites have a somewhat similar history.

Enzymes.—Allusion has already been made to the activity of these ferment-like agents in our account of protoplasm. The digestive juices are enabled to act in virtue of such catalytic agents, some acting on one, others on other varieties of food-stuff. The majority of the chemical changes in the metabolic cycle in the tissues are also brought about by similar subtle materials, which by their presence accelerate changes, though they themselves do not participate in the final products formed.

An illustration may help in the understanding of the word catalyst. If starch and water are mixed together it is conceivable that in time the two will unite, and the starch molecule split into its constituent molecules of sugar. Such a cleavage, due to the entrance of water, is called hydrolysis (splitting by water), but in these circumstances the process would occupy such a long time (perhaps years) that for practical purposes it does not occur at all. If the starch and water are reinforced by a few drops of mineral acid, and the temperature raised to boiling-point, the transformation into sugar is accelerated, and occupies but a few minutes and the acidity remains unaltered. If instead of the acid a few drops of saliva are used, the transformation occurs with even greater rapidity, and, what is more important to the well-being of the animal, the temperature need not be raised to boiling-point, but the body-temperature is the optimum. The hydrolytic agent in the saliva which has this power, and is not used up by its activity, is called an enzyme; it is able to act on a fresh supply of starch, and so *ad infinitum* ('a little leaven leaveneth the whole lump'). It, however, differs from the inorganic catalysts by being destroyed at higher temperatures, and has the properties of a colloid. The greater number of enzyme reactions are hydrolytic, but in other cases enzymes act for the carriage of other substances—for example, in the process of oxidation the enzyme may be an oxygen-carrier, not a water-carrier.

Reversible Reactions.—An important character enzymes possess is that the changes they produce are reversible. The analytic change of which an example has been given may be reversed, and become synthetic; the direction of the change is determined by the relative amount of the substances present. For instance, cane sugar can be split into its two constituent sugars, named dextrose and levulose, by a special enzyme, but, as the splitting proceeds, the synthetic process begins, and, when the dextrose and levulose are present in excess, once more they are built into the original cane-sugar. The same is generally true for other enzymes; and this is especially im-

portant in metabolic processes, for the same enzyme can both untie the bond as in katabolism, and unite the same materials together again in the anabolic phase of metabolism. For example, we have seen that the liver-cells possess the power of linking sugar molecules together for storage as glycogen, and the same enzyme which performs this action is able once more to split up the glycogen into sugar molecules when they are wanted for energy supply elsewhere.

Another instance of reversibility, although here there is no enzyme at work, occurs in the hæmoglobin of the blood. This may be selected not only because it is such a fundamental reaction in the body, but is also one which can be explained without recourse to elaborate chemical formulae. Representing hæmoglobin by the symbol Hb, and molecular oxygen by its usual symbol O_2 , what occurs in the lungs may be written as an equation:

*The reverse change occurs in the tissues; there the compound oxyhæmoglobin breaks up to supply the tissue with oxygen, so there the equation runs:

The combined equation is usually written:

the sign of equality being replaced by a double arrow. There are many different definitions or descriptions of 'life,' but that which says, 'Life is a series of reversible reactions,' is not the least instructive.

The foregoing sketch of the labours of the inferior members of the cell-community may be completed by a final reference to the more skilled workmen which comprise the nervous system. Their function is to inform the community of what is going on in the outside world by the senses, and to keep in harmony the diverse labours of the various organs. Sir Michael Foster, in summing up the questions physiology has to grapple with, concludes: 'Lastly, we have to attack the abstruse problems of how the nervous vibrations, often mysteriously attended with changes of consciousness, as well as the less subtle vibrations of the contracting muscles, are wrought out of the explosive chemical decompositions of the nervous and muscular substances — i.e. how the energy of chemical action is transmitted into and serves as the supply of that vital energy which appears as movement, feeling, thought.' A discussion of the theories held would lead us far into philosophical fields. The relation of the material and mental worlds is the domain of the psychologists.

It may not be inappropriate to conclude an article which deals with life by a few words on Death (see also LONGEVITY). In a simple organism such as the amoeba there is not only no differentiation of sex, but there is also no differentiation between the reproductive element (Weismann's germ-plasm) and the remainder of the body (Weismann's somatoplasm). When the amoeba propagates itself by dividing into two new amoebæ, the whole animal is concerned in the act of reproduction, and barring accidents the new amoeba may behave in this way indefinitely, and so may be spoken of as immortal. In this sense the only part of the body of higher animals which is immortal (in the material as opposed to the theological sense of the word) is the germ-plasm, which lives beyond us to repeat the process an infinite number of times in our descendants. The common lot of all is to die, and life in the individual is then extinct; but each individual is only a link in a long chain of lives; each link is composed of somatoplasm, the temporary harbouring-place of the germ-plasm, and from this point of view life is not something which

begins and ends like a straight line. It is rather to be compared to a circle in which a series of events is repeated over and over again.

As the prime of life is past, signs of old age begin to appear: the eyes become feeble, the hair becomes gray, the cartilages calcify, the muscles (heart included) get weaker, digestion more difficult, and metabolism in every way more and more imperfect. If this continues the machinery gradually runs down, and life is ultimately terminated by natural death. But such death from old age is comparatively rare; the common cause of death is accident, in which term disease may be included. In the activity of youth many a disease is vanquished, but as the power of resistance diminishes with increasing years, some ailment, usually upsetting more particularly some important organ, will finally find the body unable to repel its attack.

The History of Physiology.—This may be divided as Preyer did into five periods: (1) the speculative period; (2) that associated with the name of Aristotle; (3) headed by Galen, (4) by Harvey and Haller, and (5) by Müller. The first period opens with the beginning of medical science in India, China, and Egypt. The Jews were acquainted with many laws of practical hygiene and dietetics. Then came the philosophers of Greece. Matter was supposed to consist of four elements, fire, air, earth, and water. The essence of life was referred first to one and then to another of these elements by various philosophers: by Thales to water, by Anaximenes to the air, by Xenophon to the earth, by Pythagoras to fire or heat. Hippocrates, the father of medicine, about 450 B.C., was the first to proceed in a purely rational spirit. Observing carefully the facts of disease, he strove to found the art of medicine upon the results of experience. He attributed diseases to natural causes, and not to special visitations of the gods; and as already noted, he postulated a spiritual essence universally diffused; this he called Nature, Physis, and to this he ascribed the maintenance of things in their normal state, and their restoration if disturbed. The second period is headed by Aristotle, the father of natural history, about 350 B.C. He dissected many animals, and attempted to discover the uses of the various parts. It is difficult to estimate correctly the exact value of Aristotle's work in physiology; it must be measured more by the methods of research which he initiated than by the actual results achieved. Thus, to give an example of his ideas on the subject, the heart he imagined as the seat of the 'rational soul'; the nerves he supposed to arise in the heart; of their function he was ignorant. What is perhaps more surprising is that he described the brain as an inert viscous, cold and bloodless, whose only function was to cool the heart, and not comparable in importance to the other organs of the body. Erasistratus, the grandson of Aristotle, about 300 B.C., was perhaps the first to dissect carefully the human brain. He traced the connection of nerves with it, and even noticed that the complexity of the convolutions of the gray matter was greatest in man, and that they were to some extent a measure of the intelligence. The next 400 years were barren of any useful advance; the practice of medicine reached perhaps its lowest point. The literature is occupied with discussions as to the 'animal and vital spirits,' terms used before Aristotle to express the powers of living things. The animal spirits were those that ruled over those actions of living things that were supposed to be quite different from anything that takes place in things not living, while the vital spirits were those that were concerned in those processes going on in the body which were the result of purely chemical and physical laws. We no longer

discuss whether the vital spirits live in the heart and the animal in the brain, but we have not yet settled the exact relationship between the processes of the living world and those of inorganic matter.

About 150 A.D. Galen, a Roman, revived the sounder method of experimental inquiry; he is the leader of the third period. He perceived that mere dissection of dead animals give no infallible information as to the functions of the living, and accordingly performed many experiments upon living animals. He proved that during life the arteries contain blood and not air, as was thought to be the case up to that time, by simply opening a vessel of a living animal. He also directed much of his study to the brain and nervous system. He was the first to state definitely that the brain, spinal cord, and nerves are the organs of sensation, intelligence, and the originators and guides of properly ordered voluntary movements; and he finally refuted the doctrine of Aristotle by showing that the brain was hot and not cold, and by arguing also that if it were a mere cooler of the blood it need not be elaborately organised. He pointed out that the brain was of the same substance as the nerves, but softer, 'as it should necessarily be, inasmuch as it receives all the sensations, perceives all the imaginations, and then has to comprehend all the objects of the understanding, for what is soft is more easily changed than what is hard.' He discovered also that the nerves of sensation and of motion are distinct, but this was not placed on a firm basis until Magendie's work on the spinal nerve-roots in 1822. For centuries Galen exercised an undisputed sway over the practitioners of medicine and the students of allied philosophy. Even his mistakes were religiously believed in; for example, he taught that the right and left chambers of the heart were connected by apertures.

Some centuries afterwards the so-called Arabian physiology arose. Avicenna, about the year 1000, was its chief exponent. Once more, however, the discussions were about the nature and residence of the animal and vital spirits. Albertus Magnus, in the 13th century, and Paracelsus, in the 15th century, are representatives of mediæval mysticism. About the same time, during the revival of learning, the mathematicians and chemists were busy seeking to explain bodily functions in terms of mechanical, chemical, and physical laws. In the 16th century Villanovanus described correctly the action of the lungs as purifiers of the venous blood. The study of human anatomy was revived by Vesalius in Italy, and continued by Fabricius; and in the beginning of the 17th century Harvey, who had studied in Italy, made perhaps the most important of all physiological discoveries, that of the circulation of the blood.

This discovery inaugurates the fourth period of the history of physiological research; by it a sound foundation for the whole science was laid, and the development of surgery and medicine made possible. Then, after the invention of the microscope, came many active investigators; among them may be mentioned Malpighi and Leuwenhoek; and thus the foundations of Histology (q.v.) were laid. Haller, near the end of the 18th century, gave to physiology the form that it now possesses. He attempted to discard from the science all statements of a vague and mystical character, he added many minor discoveries to the store of facts, and ranged the whole in a logical sequence.

The great leader of the fifth period, Johannes Müller, during the first half of the 19th century, gave to the science a greater width. He connected as one philosophy the truths of chemical physics, comparative anatomy and physiology, and embryology. Embryology was founded as a science by

Von Baer. Cuvier developed comparative anatomy, and thus gave a foundation to the study of comparative physiology. Lamarck enunciated a certain view on evolution. Berzelius, Liebig, and Mulder placed animal chemistry upon a sound basis. The discovery of the mechanical equivalent of heat by Joule, the enunciation of cell-theory by Schleiden and Schwann, and the discovery of protoplasm as the essential constituent of the cells by Von Mohl and Du Jardin, are the great steps which have placed us in our present position. The discovery of reflex action by Marshall Hall, of inhibitory nerve action by the brothers Weber, and of the glycogenic function of the liver, and of vasomotor nerves by Claude Bernard, mark important advances. At about this time the study of protoplasm, as we now know it, begins. The conception of evolution has been rendered acceptable by Darwin's work, and the foundation of the new science of bacteriology marks a more recent milestone on the road of physiological discovery, especially on its medical side. The reader interested in history is recommended to read the late Sir Michael Foster's *History of Physiology* (1901, revised 1924).

Even to early inquirers it was obvious that the life-processes of animals are the result of the action of a set of machines which were supposed to be kept in action by the 'vital spirits.' These machines were called organs, and the work performed was spoken of as their functions. The whole body was conceived of as made up of various organs, and the labours of physiologists were directed towards discovering their functions, a work which to this day is incomplete. This may be called the first phase of physiological philosophy; it lasted until the promulgation of the cell-theory and the rapidly following discovery of protoplasm. The idea of protoplasm is to natural science of as much importance as the doctrine of the conservation of matter and energy are in chemistry and physics. The chief labours of physiologists for a very long time will be directed towards attaining exact conceptions of the nature of this protoplasm in terms of chemistry and physics. We are not able to say whether there is any abrupt distinction between ordinary matter and that which is called living matter, and which forms 'the physical basis of life.' Is it merely that living matter is more complex and unstable than ordinary matter, and the force fa

impulse in the form of ethereal and molecular vibrations; or is there some special vital force at work? If we accept the first theory we shall believe that there is no such vital force. At any rate the surest path to its discovery lies in determining how far the *objective* phenomena of life are explicable in terms of ordinary chemical and physical laws. When we find any activity of living matter which we can be certain cannot be so explained, then, and not till then, may we postulate a vital force. Supposing such a discovery ever to be made, it is necessary to observe that it will merely widen our chemistry and physics. In fairly recent years there has been a revival of the idea of 'vitalism' as an idea of specific energy, but even the 'neo-vitalists,' as they are called in their rebellion against the 'materialistic' spirit of the time, have not the superstitious ideas of the dark ages. The majority of modern physiologists use the word 'vital' in an apologetic way, not to explain phenomena they cannot understand, but as a convenient cloak for their ignorance of what at present cannot be brought into line with known chemical and physical laws. The use of such a word is especially frequent in the consideration of the processes of the mind, which, as already indicated, is the greatest of the problems of the future.

See, besides the articles named above, those on ANATOMY, ANIMAL, ANIMAL, CHEMISTRY, ANIMAL HEAT, DIET, FOOD, DEATH, LIFE, &c. Some important books are mentioned in the text. The beginner should start with an elementary text-book (Huxley's is the best). There are also text books more complete by Stewart, Starling, and Halliburton (17th ed. 1924). The fullest are those by Foster and Sharpey-Schafer.

Physiology (VEGETABLE). Vegetable physiology deals with how plants grow, and is thus concerned with the function or work of plants. It is frequently forgotten that plants, like animals, are living organisms, and consequently similar processes must go on in each. In the broad aspect, vegetable physiology is the study of the origin of life, since plants arrived before animals. Many of the processes are obscure, but the resultant is apparent in the recurrence of seed-time and harvest, in the orderly appearance of first the blade, then the ear, after that the full corn in the ear. At times the return is a hundred-fold, at others thirty-fold. A physico-chemical explanation has been sought to explain life-processes, but fails in the interpretation of phenomena apparently purely chemical. Behind all the processes there is life working in the Protoplasm (q.v.), co-ordinating all the processes and resulting in plant development as a manifestation of life. Paul plants, Apollos waters, but God alone gives the increase.

Many of the experiments referred to below can be carried out with simple apparatus, and their performance will help to elucidate the problems.

The problems involved may best be set forth starting from the planting of a seed in good ground. On completion of the period of rest, which varies in length in different plants, the dry seed will germinate when supplied with suitable conditions. Seeds may be stored in the majority of species in a dry condition for considerable periods, but sooner or later they lose their vitality. Elm seeds must be sown when they fall to the ground; turnip seed germinates better the second year after harvest. The story of minnany wheat serves best to illustrate the ingenuity of the Egyptian in satisfying the tourists' wish. It is impossible to tell if a seed is alive or dead, except by a germination test. The changes which take place during germination arrange themselves under physical, chemical, and vital changes. Water is first taken up by imbibition to the seed-coat, and then by imbibition and osmosis by the structures inside the seed-coat. The result is a physical swelling of the seed. Before growth starts, a supply of available food is necessary. The reserves in the seed are stored mainly in a solid and non-assimilable form. Water and appropriate enzymes are necessary to bring the reserves into a form which the embryo can use. These changes are known in chemistry as hydrolysis. The third series of changes follow on this, and only take place in the living seed. The embryo starts to develop and grow, and this is manifested by the splitting of the seed-coat.

Respiration starts concurrently with growth, supplying the energy necessary for vital activity. Dry peas, suspended in a muslin bag in a closed test-tube over lime-water, can be compared with soaked seeds similarly placed. In the latter only is sufficient carbon dioxide evolved in respiration to turn the lime-water milky. The energy derived from respiration may cause a rise of temperature, which can be felt as in the case of malting barley.

When supplied with suitable conditions of moisture, temperature, and aeration, the seed germinates. It has been found that soaking seeds, prior to sowing, for definite periods, varying with the kind of seed, gives quicker germination than direct sowing in the ground. The suitable temperature also varies with the kind of seed. Shepherd's

Parue will germinate in frozen ground, while tropical seeds require higher temperatures. The best all-round temperature is 22° C. At higher temperatures, varying with the species of the seed, the success in germination becomes less, until a point is reached—particular to each plant—above which the moist seed is killed. It may be noted here that in physiological processes occur three points in the intensity of external conditions, which are of supreme importance. There is a minimum below which the process is inhibited altogether, a maximum above which inhibition again occurs, and, lying between these extremes, an optimum at which the process proceeds with greatest activity. On either side of the optimum there is a lessening in activity in the process.

Absorption.—Plants living in water are able to absorb over their whole surface. Experiments show that in land-plants the root is the special absorbing organ, and the fine root-hairs, just behind the root-apex, are the special structures concerned in this. The contact between the root hairs and the soil particles is very intimate. Soil-particles adhering to root-hairs cannot be washed off, and in transplanting a seedling many of the root-hairs are torn away. These root hairs are outgrowths from the limiting layer of the root, and consist of a cellulose wall containing protoplasm and a nucleus. The centre is occupied by cell sap. Experiments demonstrate that the cell-sap is osmotically a stronger solution than the soil solution, and thus there is established a living cell acting as a dialyser. With the entry of water into the cell-sap the solution becomes weaker, and the cells internal to the limiting layer absorb water from them, and thus, in a linked chain, water is passed inward to the xylem.

Substances in solution alone can penetrate into plant-cells, as can be shown by placing seedlings in a solution of red ink in water and in water coloured with carmine in suspension respectively. Along with the water absorbed by the root hairs any substance in solution in the soil-water will pass into the cells, provided there is less of the substance in the cell-sap than outside, and provided the cell is permeable to the substance. Strong solutions in the soil, such as occur near the sea-coast and in peat-bogs, retard water-absorption of all plants, and in those localities the physiological drought of the plants accounts for the characteristic vegetation in such areas. It must be borne in mind that the process of absorption is controlled quantitatively by the protoplasm, which determines the amount of sap solution taken in.

Transpiration.—Plants living in water are able to absorb over their whole surface. Absorption is intimately connected with other processes in the plant, and is also influenced by external factors in the soil, of which the chief are aeration, water-content, chemical composition, temperature, &c.

The quantity of water absorbed sets up pressure in the plant, and at some periods of the year the pressure of absorbed water is considerable, as can be shown by attaching a glass tube to a decapitated vine or fuchsia. Watering the plant with warm water generally secures a satisfactory result. This root pressure is the explanation of bleeding from pruned trees, such as vines, birches, and maples. The water may be forced out through special pores in saxifrages, fuchsias, balsams, or as dew in the early mornings on grasses and the edge of the leaf of lady's mantle. Exudation, as this process is termed, occurs only when conditions are unfavourable to transpiration, and may be looked upon as a safety arrangement to protect the intercellular spaces from flooding. The fluid found

in nectaries and in pitcher plants is secreted by osmosis.

Experiments made by growing plants by placing twigs in coloured water demonstrate that absorbed substances pass from root to leaf. If the stem of a plant so treated be cut across, the wood (xylem) alone is stained. Removal of a ring of bark does not interfere with the ascent of the solution. Trees hollowed by decay still carry fresh leaves, showing that, generally, it is the youngest wood in which the sap ascends. On reaching the leaves the water is given off as water-vapour. This unseen loss of water accounts for the wilting of cut flowers and branches. If a freshly-cut branch is fitted to a glass tube filled with water, whose end dips under mercury, the loss of water from the leaves will draw up the mercury, thus measuring the force of the transpiration pull. In herbaceous plants, root-pressure acting from below and the transpiration pull from above account for the movement of sap. Much has been written concerning the ascent of sap in tall trees. Let it be remembered that every tree began as a seedling, and reached its height by growth. In the seedling water was raised by root-pressure and the transpiration pull. Further, water adheres to the sides of the conducting elements through which it passes, and there is also the cohesion of water in a column. Such a column of water transmits a pull like a solid rod, and even in the tallest tree root-pressure and the transpiration pull are the forces at work.

Transpiration.—A simple experiment of enclosing a leaf in a bottle serves to show that water-vapour is given off from a leaf. The process is called transpiration. The actual amount of water lost as vapour can be measured accurately by weighing, but is by no means constant even in the same leaf. It varies with the age of the leaf and with external conditions. Leaves in ordinary plants transpire more than stems, and more transpiration takes place through the under side of a leaf, because there are more stomata present. Transpiration resembles evaporation in that both are influenced by temperature, humidity of the air, and wind; but light increases transpiration, and has little effect on evaporation. Light increases the permeability of the protoplasm, with a consequent increase in transpiration.

Transpiration is not essential to plant growth, as water plants do not transpire. It is an unavoidable accompaniment of a land existence. Within limits transpiration is regulated by the stomata. When transpiration exceeds absorption the leaves wilt, as the turgor of the cells due to the pressure of the cell-sap no longer distends the cell-walls. Thus, a plant in a dry pot wilts because it obtains no water from the dry soil. Watering a greenhouse plant with cold water will cause wilting, as the lower temperature retards absorption from the root. In winter our trees are leafless, not because there is no water in the soil, but because the soil temperature is too low to admit of absorption keeping pace with transpiration. If an ordinary plant is watered with sea-water, wilting results because the salt retards absorption. These two cases illustrate the phenomenon of physiological drought—water is present in quantity, but is not attainable in sufficient quantity for the plant. The leaves of trees in a strong wind on a bright day often flag, and in dry bright weather even herbs may wilt towards the close of a windy day. During the night the plants recover, and the leaves resume their normal position. This is because in darkness transpiration is reduced, and the roots are able to absorb enough water to make the cells again turgid.

In Ecology (q.v.) an attempt is made to classify plants in relation to factors of their environment. One of the most important factors in the environ-

ment is water. Plants which are adapted to conserving their water-supply are called xerophytes. The limitation in loss of water from xerophytes is accomplished by reduction in the size of the leaf, as in the heather and yew; in extreme cases by the replacement of the leaf by spines, as in the whin; by the lowly habit of the plant, as in the house-leek; by the position of the leaves with relation to each other and with regard to the sun's rays, as in the Eucalyptus, where the leaves are set edgewise to the sun's rays at midday; and by rolling and curling of the leaf, as in many grasses.

The surface of the leaf may be covered with cuticle, giving the leaf a varnished appearance, as in holly and laurel; or the leaf may have a coating of wax on the outside, such as is seen in the cabbage; or there may be a covering of hairs, as in the edelweiss. The cuticle and wax prevent the escape of water from inside, while the hairs entangle the water-vapour as it is given off, forming an artificially moist atmosphere on the surface, just as a thick tweed collects the moisture in a fog. The stomata may be sunk in pits, as in the Scots pine; or the stomata may be in grooves, as in the grasses. In many xerophytes there is water storage, giving fleshy leaves as in the aloe and stonecrop.

Other plants always have abundance of water, and are known as hygrophytes. Their leaves are large and thin, and there are devices for draining water from the surface, as in the arum. Plants which at one season show xerophytic adaptations and at another hygrophytic adaptations are called trophophytes. This class includes the deciduous trees in this country, the bulbous plants, and the herbaceous perennials.

In water plants (hydrophytes) the adaptations are concerned in the maintenance of the air supply, and an account of their peculiarities is given under *Respiration*.

Composition of Plants.—All the elements found in plants are obtained from the soil except oxygen and carbon, which are obtained from air. All dissolved diffusible substances in the soil are not used by the plant, and they cease to enter when the concentration in the cell sap equals that of the outside solution. Useful substances are assimilated—that is, built up into other forms in the plant—and are constantly absorbed. Some plants use more of one element than of another, and a soil eventually becomes exhausted if the same crop be continuously grown on it. There is need, therefore, for rotation of crops and the use of manures to maintain fertility of the soil.

Plants may be grown in pure sand or in water, provided the essential elements are supplied in suitable form. Various combinations of the necessary salts are to be found in books. A useful water culture may be made up from calcium nitrate (1 gramme), ferric phosphate (.5 gr.), potassium nitrate (.25 gr.), magnesium sulphate (.25 gr.), water (1000 c.c.), and on it such plants as buckwheat or maize can be successfully grown. By leaving out one or other of the essential elements, comparisons can be made between growth in the normal culture and in a culture lacking any particular element. The fact that hyacinth bulbs grow to flower in water, and that seeds germinate in moisture, merely that there are reserves stored away which are available for growth.

The more important elements in the plant, determined by analysis of the gases evolved and the plant ash, are carbon, hydrogen, oxygen, nitrogen, sulphur, phosphorus, calcium, potassium, magnesium, iron, chlorine, and sodium. This analysis of the dead plant yields no evidence of how the elements are combined during life in the protoplasm any more than the analysis of a gold watch into

gold, iron, copper, silicon gives information of the structure of the watch.

Metabolism.—The substances taken in by the root-hairs in solution, and the gases taken in mainly by the leaf, undergo profound changes. Carbon is absorbed by the stomata as carbon dioxide. Through the action of light the chlorophyll, working in conjunction with the protoplasm of the cells, breaks down the carbon dioxide into carbon, which is assimilated, and oxygen, which is returned to the atmosphere. (Chlorophyll only develops in light; seedlings or plants grown in the dark are yellow, owing to the absence of chlorophyll, and are said to be etiolated. Iron is also necessary for the development of chlorophyll, and plants grown without sufficient iron suffer from chlorosis.)

The spectrum of chlorophyll shows absorption-bands in the red and violet with less marked ones in the yellow. This light energy is used in carbon fixation, the first visible product of which is the appearance of starch in the leaf. That light is essential for the process can be shown by placing a tinfoil stencil on the leaf, when only the portions of the leaf exposed to light will give a starch reaction. The necessity of chlorophyll for starch formation can be demonstrated by testing a variegated leaf for starch.

Carbon fixation is conditioned both by external and internal factors. Temperature, light, carbon dioxide, and water are the chief external factors, while the amount of chlorophyll and certain unknown factors are internal. In connection with the external factors F. F. Blackman established the law of limiting factors: 'When a process is conditioned as to its rapidity by a number of separate factors, the rate of the process is limited by the pace of the slowest factor.' For example, temperature, light, and carbon dioxide supply are so closely related that increasing any one without increasing the others in due proportion will only lead to a quickening of the rate of the process over a short range, and then further increase in the factor gives no further increase in rapidity, because the others are limiting.

Blackman was also instrumental in establishing the effect of a time factor. Thus he found that, provided light intensity and the carbon dioxide supply were adequate, the rate of carbon fixation rose with increasing temperature, but at higher temperatures the initial rate was not maintained indefinitely, but slowed down regularly at a rate depending on the temperature. Further, the higher the temperature the more rapid the fall, but the falling-off at any given temperature is fastest at the beginning and becomes less rapid.

The exact nature of the process has been much discussed, as also the nature of the first-formed product. Probably formaldehyde is first formed, and this is condensed into a sugar from which starch is formed when the sugar concentration reaches a certain point. Be this as it may, the whole produce of agriculture, horticulture, and forestry is manufactured by the green plant from the carbon dioxide of the atmosphere. The balance of life on this sphere depends on this process, because through it the concentration of carbon dioxide in the air is maintained, its place being taken by oxygen. The volume of oxygen returned to the atmosphere is equal to the volume of carbon dioxide taken in, and this favours the supposition that formaldehyde is first formed. The reaction may be represented—

If little is really known concerning the process of carbon fixation, still less is known regarding the building-up of the more complex compounds, particularly protein formation. For the ordinary

green plant the nitrogen supply is the nitrates in the soil. Potassium salts are essential. Light is essential only in that the radiant energy of light is made use of in forming carbohydrates, which is a requisite in the formation of proteins.

The food elaborated in the green leaf is conveyed to the growing points and to storage organs. Much of the food cannot be translocated as it is found in the leaf, but must be changed to soluble and more diffusible compounds so as to pass from cell to cell. This change preparatory to translocation is effected by enzymes, which are produced by the protoplasm. Starch, a solid, is acted upon by diastase and transported as a soluble sugar—maltose—though the maltose is generally changed by another enzyme into glucose. The manufactured food is conveyed over long distances by the phloem, as tinging experiments show. In addition, much passes from cell to cell by diffusion.

Respiration, or breathing, consists in the taking in of oxygen and the evolution of carbon dioxide with the liberation of energy. It is the reverse process of carbon fixation in that it is a destructive process, and takes place at all times to a greater or less extent in all living cells. In dry seeds the process is so slow that air from them does not turn lime-water milky. Seeds which have been soaked for twenty-four hours respire freely and turn lime-water milky. Every living cell throughout the plant must be supplied with air, and the air, after it has been deprived of its oxygen, must be renewed. Air diffuses through the stomata of a land plant which are in communication with the respiratory cavity. From this the air diffuses out into the intercellular spaces, which are all in communication with each other. It is possible to blow through the stalk of certain leaves and see the air issuing from the stomata, thus reversing the natural passage. Better results can be obtained by inserting the leaf stalk into a bottle filled with water to cover the end of the stalk. Air is then sucked from the bottle, and a stream of air bubbles can be seen issuing from the cut end. Water plants (hydrophytes) have to contend with the scarcity of air in their environment. Extensive air canals are frequently developed, giving the spongy feeling to the leaves and stems of the Mare's Tail or the Water Lily. The activity of respiration can be estimated by measuring the amount of carbon dioxide evolved by the indicator method, or by passing the gas through baryta water and determining the amount of barium carbonate precipitated. The volume of oxygen taken in is equal to the volume of carbon dioxide liberated in ordinary plants. In succulent plants more oxygen is taken in than carbon dioxide liberated, as there is an accumulation of organic acids in these plants with a fixation of oxygen. Seeds with oily reserve give a respiratory quotient less than unity as oxygen is used in changing the reserves into carbohydrates.

The intensity of respiration varies with both internal factors in the plant and external factors. It is generally more active in young plants—e.g. seedlings and young tissues (buds) respire more actively than the older parts of the plant. Temperature, the nature of the food supply, water and light, exert an influence on respiration.

It is generally accepted that sugar, probably glucose, is the material chiefly used in respiration. Proteins are also consumed, and at times much of the food manufactured by the plants is consumed in respiration to obtain the energy necessary for its activities.

There is thus in the plant a continual process of construction and destruction going on, in which proteins are involved. The contrast between constructive metabolism or anabolism, and destructive

metabolism or katabolism, may be shown as in the figure. It is difficult to determine whether a compound is a synthetic or analytic product, and especially so when one remembers the profound changes brought about by killing protoplasm. Enzymes are bound up in most of the processes, and there has been a tendency to explain life-processes in terms of enzyme activity. Protoplasm cannot, however, be considered merely as a complex of various enzymes. Enzymes are workers in the service of protoplasm, formed by it when required, used in its work, and destroyed when no longer necessary.

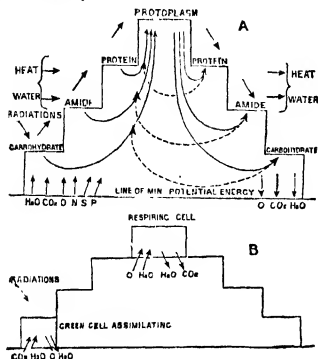

Fig. 1.

Most plants do not immediately die when deprived of oxygen, but growth, movement, irritability, and activity in general ceases. Soaked pea seeds, inserted into a test-tube filled with mercury inverted over a saucer of mercury, evolve considerable amounts of carbon dioxide. If the primary roots be measured before insertion no elongation will be found on the conclusion of the experiment. The carbon dioxide here has no relation to atmospheric oxygen, but is the result of the breaking-down of the organic substances in the seed. Closely related with this anaerobic respiration is the phenomenon of fermentation. The fermentation of sugar by yeast results in the splitting up of sugar into alcohol and carbon dioxide, with the liberation of energy. It is, however, a wasteful method of obtaining energy, since over thirty times as much sugar must be consumed to yield the same amount of energy as by direct oxidation. Lactic acid fermentation seen in the souring of milk, and acetic fermentation seen in souring of beer and claret, are fermentations due to the activity of bacteria.

Growth is the outward expression of the metabolism of the plant. Metabolism has two sides, a building up and a breaking-down. When the building-up processes are more intense than the breaking-down processes, growth results. The most accurate method of measuring growth is by the increase in dry weight. Mere increase in size does not necessarily indicate growth, as seeds grown in the dark, though they have long spindly stems, actually in dry weight are less than the dry weight of the seeds, because the reserves have been used up in respiration and there has been no new matter formed. The root of the seedling pursues a spiral course amongst the soil particles. It is irritable to gravity, and grows downwards; to contact, and moves away from obstructions; to variations in the amount of water and air in the soil, hence the roots are found at the sides of a flower-pot. Branching takes place, increasing the absorptive

area and securing better anchorage. The root not only increases in length but generally increases in thickness.

The shoot generally emerges from the soil with arched shoulders and bent head, thus gaining a greater leverage for forcing its way through the soil and protecting the delicate growing point at the tip in its passage through the soil. Free from the soil, the shoot, by greater growth on the under side, becomes straight, and like the root elongates in a spiral course. The shoot is irritable to gravity, light, and other stimuli, which are discussed under PLANTS (MOVEMENTS OF). Growth in thickness takes place in the shoot. The rate of elongation varies greatly in different plants. Bamboos may lengthen a foot in twenty-four hours. Cereal crops in this country attain their full height in three months, while trees go on growing for hundreds of years. Further, the rate of elongation is not constant in any one plant, as growth is more active in spring, and the rate of growth decreases towards autumn in this country where there is a seasonable periodicity in the growth rate. There is also a diurnal periodicity, as elongation is greater at night than by day. Further, the rate of growth varies from time to time without any change in the external conditions.

Elongation does not take place uniformly throughout the length of root and stem, as the greatest growth in length takes place just behind the apex. Fig. 2 represents the lengthening of equal divisions of a bean root after twenty-four hours' growth. Each internode of the shoot shows a similar distribution of growth, and the terminal region of elongation embraces several internodes. In certain cases—e.g. grasses—the elongation takes place at the base of the internode, and the growth is called basipetal. Leaf enlargement is mainly from the base, the enlarging region being near the stem. Growth may result in a shortening, and is sometimes pronounced, as in the pull-roots of crows, where the thick roots developed after flowering drag the corn downwards to the correct depth in the soil.

Fig. 2.

a, bean root divided into equal divisions; b, same root 24 hours later.

It is necessary to remember that all these changes manifested in growth in the living organisms, plant or animal, take place in the living cell. They are controlled by the protoplasm, and each cell contributes its share so long as it is alive. Even dead cells still serve the plant by giving strength and rigidity to the whole. Each cell starts from the division of a previous cell. A newly-formed cell consists normally of a cellulose cell-wall, dense protoplasm, and a relatively large nucleus. As the protoplasm works, it increases in amount for a time, then vacuoles appear, until in the adult cell the protoplasm forms a membrane lining the cell-wall and surrounding a large sap vacuole. The nucleus lies along one of the side walls, and appears relatively small, as its increase in size has not kept pace with that of the cell. The whole increase has taken place by the food formed through the agency of the chlorophyll apparatus. Much of this

food has been destroyed, however, in order to obtain energy. Meantime the cell-wall has increased in bulk through the activity of the protoplasm. This increase is owing to the distension (turgor) of the cell, brought about by the solution in the sap vacuole. When the wall is stretched, new material can most readily be added. The new material may be deposited between the original particles of the cell-wall, giving what is called growth by intussusception, or the new material may be laid down against the inside of the wall, when growth by apposition is said to occur. Generally both processes are at work. The new material may be cellulose, or it may be wood (lignin), or cork (suberin), or gum (mucilage), and in this way the chemical nature and the physical properties of the cell-wall are changed by the activity of the protoplasm. In appearance the cell-wall has now assumed its final shape and markings. Each cell passes through one grand phase of growth, and only one, unless it is stimulated in a suitable way—e.g. in fertilisation and in response to certain wound stimuli. The plant propagator makes use of this fact in raising plants by cuttings, layers, &c. Certain cells at the growing-points remain for long periods in the embryonic condition, but these are exceptions.

Every plant is composed of cells, and, as is indicated above, the cell starts by division, enlarges, and then reaches a permanent stage. Enlargement of plants and their component organs does not take place at a uniform rate throughout their development. Growth starts slowly, the rate gradually increases until a maximum is reached, after which the rate progressively decreases until enlargement ceases. Sachs introduced the term 'grand period of growth' to define this march of the rate of growth; other workers have analysed the progress of the growth-rate more fully, and find each grand period curve made up of a series of S-shaped curves. Blackman has introduced the idea of the law of compound interest governing the rate of growth, and other workers the law of autocatalytic reaction. The plant is, however, a living organism attuned to its surroundings, and influenced by them not only in the present but also by those of the past. This principle of predetermination is important, and helps to elucidate certain aspects in physiology whose explanation has been lacking.

Growth is conditioned by temperature, and an increase of temperature to a limit increases growth. Beyond this limit growth is retarded. The action of light is both direct and indirect. Both the quantity of light, its quality, and its duration have profound influence on growth. The elongation of the stem is retarded in light; leaves may remain dwarf in darkness, as in the pea, or may grow as much as in light, as in wheat, the difference apparently being connected with the amount of carbohydrate present. Water is another conditioning factor, as a cell to grow must be turgid. Both the humidity of the air and the moisture must be taken into account. Further, the vegetative and the reproductive phases in the plant are antagonistic. Thus dryness favours flowering; witness the early flowering of plants growing on walls. Nutrition is another factor, both in respect of the supply of food and the supply of raw material. In increasing the supply of the latter, experiment has shown the necessity of maintaining a balance and the incidence of limiting factors. Internally there is the possibility of growth being controlled by growth-promoting substances or auxinones. The nature of the growth may be determined by hormones, though the presence of hormones has not been demonstrated in the plant. Vitamins, so necessary in the animal diet, are produced only in the plant world.

Irritability is a fundamental property of protoplasm, by which organisms are able to respond to a stimulus by a release of energy according to their inherent character and according to the means at their disposal. The manifestation of irritability depends on the tonic conditions, existent and previous, and on the stage of development. A perceptible response is only produced when the stimulus reaches a certain minimal intensity, and, between the application of the stimulus and the response, a latent period or interval of non-responsiveness always intervenes. In plants, as in animals, there is no exact relation between the intensity of the stimulus and the amount of response, and beyond a certain intensity of stimulus the response may alter. After-effects also occur, as exhibited in the continuance of response after the stimulus has ceased to act.

The change of intensity of physiological processes, with variations in the tonic conditions, is a manifestation of irritability. This may be observed in the rate of circulation of protoplasm within the cell of *Elaeagnus*, *Tradescantia*, *Vallisneria*, *Urtica*, *Chara*, *Nitella*, &c. In *Elaeagnus* the whole protoplasm is in rotation, and the chloroplasts can be observed gliding round the cell walls. In the staminal hairs of *Tradescantia*, the denser particles in the protoplasm can be seen moving along the protoplasmic threads. The rate of movement depends on the temperature. The breath of the observer is sufficient to raise the temperature of the slide under inspection with a quickening of the movement. Free movement of the Myxomycetes, which creep about like an Amoeba, and of zoospores and gametes controlled by special organs (cilia), is, in its direction, a manifestation of irritability. Even in plants fixed to their substratum movements of growth and movements of variation, in response to external stimuli, occur, and are discussed under movements of plants. Reproduction is a manifestation of irritability depending on cell division. The products may be specially prepared, and then normally the stimulus of fusion is necessary prior to further development. This is sexual reproduction, resulting in numerical increase with the possibility of qualitative differences between the offspring. In vegetative reproduction, which gives numerical increase only, there is no special preparation of the products of division, and consequently no need for fusion. The fundamental difference underlying the two methods of reproduction will be found under other articles.

Physostigma. See CALABAR BEAN, the alkaloid of which, a valuable drug, is called Eserin or Physostigmine.

Physostomi. See BONY FISHES.

Phytolaccæ. See IVORY (VEGETABLE).

Phytolaccææ, a family of centrospermous plants related to *Chenopodiaceæ*, comprising over 100 species, mostly North, Central, South American, the rest distributed over Australia, Africa, China, and Hawaii. Most are herbs, but there are some trees too included, the best known being *Phytolacca dioica*, a native of South America, and there called Ombá, but cultivated as a shade tree in Spain under the names of Bella sombra and Sapote. *Phytolacca americana* has berries that served to colour wine

and liquors, and for this purpose it was introduced into all wine-growing European countries, where it has spread to such an extent that nobody would suspect its foreign origin. Many species are used medicinally in their own homes, and scientific examination of these plants may yet enrich the pharmacopœia of other countries.

Piacenza, a city of Northern Italy, on the right bank of the Po, a little below its confluence with the Trebbia, by rail 43 miles S.E. of Milan and 35 N.W. of Parma. Situated where the prolongation N. of the Via Emilia to Milan crossed the Po at the last convenient crossing-place (eastwards) of that river, and at the intersection of the Via Postumia from Cremona to Bertona (Tortona) and Genoa, it has always been an important city, both strategically and commercially, since its foundation (as *Piacentia*) by the Romans in 218 B.C. It is defended with bastioned walls and an outer ring of forts. Its streets are broad and regular, their arrangement being a survival from the Roman plan. The cathedral, in the Lombard-Romanesque style (1122-1233), has an immense crypt, a campanile 223 feet high, and paintings by L. Curraeci, Guercino, and others. The church of Sant'Antonio, the original cathedral, was perhaps founded in 324, but has been several times rebuilt. S. Savino is a fine Romanesque church of 903 (well restored in 1903). The church of Santa Maria della Campagna is adorned with fine frescoes by Pordenone; and it was for San Sisto that Raphael painted the celebrated Sistine Madonna, sold in 1754 by the monks to Frederick Augustus of Saxony. Among the other buildings are the Palazzo Farnese (1558), once a sumptuous edifice, but since 1800 in use as barracks; the communal palace, one of the finest in Italy (1281), its lower story built of marble and the upper of brick; the palace of justice, and others. A couple of miles to the east of the city is the theological seminary founded by Cardinal Alberoni. The municipal library contains 120,000 volumes. The principal square is adorned with colossal bronze equestrian statues of Alessandro and Raimondo Farnese. Manufactures of automobiles, silks, cottons, pottery, hats, &c., are carried on. The more notable facts in the history of Piacenza have been its capture by the Gauls in 200 and by Totila in 546, the meeting here of two church councils in 1005 and 1132, its active zeal as a member of the Lombard League in the 12th century, the sacking of it by Francesco Sforza in 1447, and its union with Parma (q.v.). Pop. (1921) 43,717. The province has an area of 950 square miles and a pop. of 281,256.

Pia Mater. See BRAIN.

Piana dei Greci, a town of Sicily, 10 miles S.W. of Palermo. It was the chief Albanian colony in Sicily in the 15th century. Pop. 10,000.

Pianoforte (Ital. *piano*, 'soft,' and *forte*, 'loud'), a stringed musical instrument, played by keys, developed out of the Clavichord (q.v.) and Harpsichord (q.v.), from which the pianoforte differs principally in the introduction, to put the strings in vibration, of hammers connected with the keys by a mechanism that enables the player to modify at will the intensity of the sounds; whence the name of the instrument. The invention of the pianoforte must be accredited to the Italian Bartolommeo Cristofori (q.v.), who produced the instrument early in the 18th century. Other claimants are a German organist of the name of Schroter, and Marinus, a French harpsichord maker. The first pianoforte seen in England was made at Rome by Father Wood, an English monk there. In Germany the invention met with more rapid encouragement and development than in Italy. The Silbermanns in Strasburg and Stein of Augs-

burg improved the discoveries of their countryman Schroter, and many maintain that the pianoforte is an independent invention indigenous to Germany. In England the manufacture of the instrument was at first chiefly by foreigners, principally Italians. Italian pianoforte-makers opened many shops, but the English makers ultimately rivalled and surpassed them. The English pianoforte has been brought to its present perfection by Broadwood, Collard, Brinsmead, and others. Edward and Pleyel made many improvements in France; Germany has long been famous for its pianos, including those of Bechstein and of Bluthner, while the Bösendorfer is of Austrian make; and the American pianos of Steinway are well known.

The compass of the early pianoforte was, like that of the harpsichord, four to five octaves, and has gradually increased to seven octaves, or occasionally more. The most natural of the various forms which the instrument assumes is that of the grand pianoforte, derived from the harpsichord, with the strings placed horizontally, and parallel to the keys. The strings are stretched across a compound frame of wood and metal, composed of bars, rods, and strengtheners of various kinds—appliances necessary to resist the enormous tension. This framework includes a wooden sound-board. The mechanism by which hammers are connected with the keys is called the *action* of the instrument. In the earliest pianofortes the hammer was raised from below by a button attached to an upright wire fixed on the back-end of the key. The impulse given to the hammer caused it to strike the string, after which it immediately fell back on the button, leaving the string free to vibrate. This was called the *single action*. As the hammer, when resting on the button with the key pressed down, was thus necessarily at a little distance from the string, the effectual working of this action required that a certain impetus should be communicated to the hammer to enable it to touch the string. Hence it was impossible to play very piano, and it was found that, if the hammer was adjusted so as to be too close to the string when resting on the button, it was apt not to leave the string till after the blow had been given, thereby deadening the sound. This defect was remedied by a jointed upright piece called the *hopper*, attached to the back-end of the key, in place of the wire and button. When the key was pressed down the hopper, engaging in a notch in the lower side of the hammer, lifted it so close to the hammer that the lightest possible pressure caused it to strike; and at this moment, when the key was still pressed down, the jointed part of the hopper, coming in contact with a fixed button as it rose, escaped from the notch, and let the hammer fall clear away from the string. To prevent the hammer from rebounding on the string a projection called the *check* was fixed on the end of the key, which caught the edge of the hammer as it fell, and held it firmly enough to prevent it from rising. A necessary part of the action is the *dampers*, which limits the duration of each particular note, so as to cause it to cease to sound as soon as the pressure is removed from the key. It consists of a piece of leather resting on the top of the string and connected with the back-part of the key by a vertical wire. When any key is pressed down its damper is raised off the string, so as to allow the sound produced to be clear and open; but immediately on the finger being lifted off the key the damper-wire falls, and the damper again presses on the string, muffling and stopping the vibration. The pianoforte possesses two pedals, the loud and the soft. By the former the dampers are raised, the result of which is to prolong the sound of the notes and cause them to run into one another. The soft

pedal, on the contrary, diminishes the sound by removing a string from the impact of each of the hammers, or in some way weakening the stroke of the hammers. Some modern pianos have a third pedal, which sustains any notes held down when the pedal is applied, but does not sustain any struck subsequently. One further frequent and important addition to the action may be alluded to. In the mechanism above described the key must rise to its position of rest before the hopper will again engage in the notch of the hammer for another stroke; hence a note cannot be repeated until time has been allowed for the full rise of the key. The *repetition action* is a contrivance, varying in different instruments, for getting rid of this defect by holding up the hammer at a certain height while the key is returning.

Great difference of detail exists in the actions of different makers. Some are more complicated than others; but in all are to be found the same essential parts, only modified in shape and arrangement. The subjoined figure represents one of the simplest grand pianoforte actions. A is the

key; B, the lever which raises the hammer; C, the hammer; D, the string; and E, the damper; F is the button which catches the lever after it has struck the hammer; G, the check; H, the damper pedal lifter; I, the spring; and K, K, K are rails and sockets. Formerly the strings of the pianoforte were all of thin wire; now the bass strings are very thick, and coated with a fine coil of copper-wire; and the thickness, strength, and tension of the strings all diminish from the lower to the upper notes. A grand pianoforte has three strings to each of the upper and middle notes, and now, generally, only two to the lower notes, and one to the lowest octave. In most modern pianos a system of overstringing has been adopted, whereby the lower strings are arranged to cross part of the others obliquely, to distribute the tension more equally.

Besides the full or concert grand, there is the semi-grand or square piano with curtailed keyboard, and there is the cottage piano, of which the upright grand is merely a larger form. In the cottage piano the strings run vertically from top to bottom of the instrument; and the difference in form necessitates alterations in the details of the action, but the general principle is the same. The pianette is a small form of the cottage. The pianoforte in its various forms has attained a widespread popularity, owing chiefly to the fact that it can render harmony; though the violin is a serious rival to it in domestic circles.

The improvement of the keyboard of the pianoforte has from time to time been attempted. Thus in 1882 the Hungarian, Paul von Jankó (1856-1919), patented his piano with six keyboards, rising in tiers above one another in the manner of an organ, so arranged that tenths and twelfths could be easily spanned by reaching a finger to a keyboard above or below that on which the hand was travelling; and, with a sweep of the wrist, an arpeggio could be executed through the whole compass of the instrument. But experience proved the invention to be impracticable. In 1921 Emanuel Moor, an Englishman of Hungarian descent, brought

forward a two-manual octave-coupler pianoforte, the upper keyboard giving tones an octave above those of the lower and capable of being coupled or uncoupled with it, the whole arrangement making possible the playing with facility of octaves, arpeggios, and widely extended chords. In an 'African piano' there are seventeen notes for a complex of tones corresponding to our octave. A pianoforte has been made with 11 scale proceeding in quarter-tones in place of the usual semitones.

The *Sostenente* or *Sostinente* pianoforte produces a sustained sound. But by acquiring this power it loses its distinctive character, and is a pianoforte only in name. The *hurdy-gurdy* is the genus of *sostenente* keyed instruments. Subsequently the principle was applied to the harpsichord and then to the pianoforte.

Music for the pianoforte is written in two staves, though some modern composers employ three or even four, and with the treble and bass clefs. Many of the most eminent musicians have devoted themselves to composing for the pianoforte, and some, of whom the most conspicuous is Chopin, have almost entirely confined themselves to that instrument. Amongst the greatest modern pianists have been Madame Schumann, Liszt, Rubinstein, Busoni, Cortot, and Paderewski.

Mechanical methods have been employed in the playing of the pianoforte. Different devices have been used, but the general principle of all is the same—a music roll as drawn over a wind-chest sets in motion, by means of perforations representing the duration and pitch of each note to be reproduced, a series of hammers which serve in playing as substitutes for the human fingers. The mechanism was formerly worked by foot pedals, but now generally by motor attachment. The earliest devices known as Piano-players were independent machines that could be moved up to the pianoforte keyboard, but these have generally given place to Player-pianos in which the player action is contained within the pianoforte itself. Now practically every standard pianoforte can be had in combination with a player. Contrivances of the sort are only semi-automatic in character, their action as it proceeds allowing of modification in speed and force by means of various controls, and it has been claimed that a performer can put an individual interpretation into music for which his manual technique would be quite insufficient. At the same time great pianists make records for mechanically-operated pianofortes, and by later 'editing' of their interpretations are enabled finally to produce in permanent form the best work of which they are capable; in this way, despite early scepticism, mechanical pianofortes must be held to have achieved an artistic and not merely a commercial success.

See Rimbaud, *History of the Pianoforte* (1860); Spillman, *History of the American Pianoforte* (1890); Hopkins, *The Pianoforte* (1896); Oscar Bie, *The History of the Pianoforte and Pianoforte Players* (trans. 1899); Krehbiel, *The Pianoforte and its Music* (1923); Westoby, *The History of Pianoforte Music* (1923); Grove's *Dictionary of Music and Musicians* (new ed. 1904 et seq.); works on the great pianists by Taahe (1901) and Ehrlich (1920); the histories of musical instruments; and works on mechanically-operated pianofortes by Newman (1920), Drake (1922), Wilson (1923).

Piano-player. See **PIANOFORTE**.

Piarists, or 'Fathers of Pious Schools,' a religious congregation for the education of children, especially poor boys, founded at Rome by a Spanish priest, Joseph of Calasanza, in 1597, confirmed by Gregory XVI., and active in Italy, central Europe, Poland, Spain, and elsewhere.

Piassaba, Piassava. See **FIBROUS SUBSTANCES, PALM**.

Piastre (Gr. and Lat. *emplastron*, 'a plaster'; in the Romance languages, 'anything spread out or flat,' 'a plate,' 'a coin'), an old Spanish silver coin worth about 4s. Divided into eight silver reals, it was termed a *piece of eight*, the name familiar from stories of the Spanish Main; from this the symbol for the dollar was probably derived (see DOLLAR). The Italian *piastre*, or *scudo*, was nearly equal to it in value. The Turkish *piastre* is a nickel coin worth about 2d. The Turkish *lira* (£T) contains 100 *piastres*. Pieces of 2, 5, 10, and 20 *piastres* are struck in silver.

Piatigorsk, a town in Northern Caucasia, at the southern foot of Mount Beshtan (4587 feet), facing Mount Elburz and the Caucasus Mountains, and 124 miles by rail N.W. of Vladikavkaz, is celebrated for its sulphur-springs. Ranging from 83° 7' to 117° 5' E. in longitude, they are useful for abdominal and rheumatic affections. Pop. 40,000.

Piatra, a town of Moldavia, 60 miles W. by S. of Jassy, romantically situated on the Bistritza, at the (eastern) foot of the Carpathians, has a trade in timber and a pop. of 20,000.

Piahy, a north-eastern state of Brazil, east of the river Paranhya, consists mostly of plain. The climate is hot with long droughts. Horses, cattle, and mules, cotton, timber, fibres, are the chief products. Gold and lead are mined, and there is some industry (cotton-spinning, meat-canning). Area, 95,000 sq. m.; pop. 600,000. The capital is Therezina, the chief commercial town Paranhya, the port Amarração.

Piazza (more fully *Piazza Armerina*), an episcopal town of Sicily, with a 15th-century cathedral with a fine campanile, 16 miles S.E. of Caltanissetta. pop. 44,000.

Piazzi, GIUSEPPE, Italian astronomer, was born at Ponte in the Valtellina, 16th July 1746, and entered the order of the Theatins at Milan in 1764. After holding professorial chairs of Philosophy, Mathematics, and Theology at Genoa, Malta, Ravenna, and Rome, he was appointed in 1780 to the chair of Mathematics in Palermo; and there, with the aid of government, he established an observatory in 1789. The first task he set himself to was to make a catalogue of the stars, published in 1803, and again extended in 1814. On the night of the 1st January 1801 he discovered a new planet, the first of the group of planetoids between Mars and Jupiter, and named it Ceres. He died, 22d July 1820, at Naples.

Pibroch (Gaelic, *piobaireachd*, from English *pipe*), a form of bagpipe music, generally of a warlike character, including marches, dirges, &c. The rhythm is very irregular and difficult for a stranger to follow, but when played by a good piper it has a very powerful effect. The earliest mention of the military music of the bagpipe is in 1594 at the battle of Glenlivet, but the various pibrochs belonging to the different clans are mostly of modern composition.

Picardy (*Picardie*), an ancient province in the north of France, was bounded on the W. by the English Channel, and on the E. by Champagne. The capital was Amiens. It now forms the department of Somme, and portions of Aisne and Pas-de-Calais.

Picaresque. See NOVELS.

Picasso, PABLO, or, properly, PABLO RUIZ, Spanish artist, born in 1881 at Málaga, received his art education at Barcelona, where his father was a professor. He early displayed ability, and by his inventiveness and versatility rose high in the ranks of the Post-Impressionists. Drawing

inspiration from El Greco and from Cézanne, he arrived at the formulation of cubism, though his fellow-artist Braque became perhaps the visible head of the school. Picasso, indeed, even abandoned cubism.

Picayune, a name derived from the Carib language, and used in Louisiana for a small coin worth 63 cents, current in the United States before 1857, and known in different states by various names (fourpence, fipence, fip, sixpence, &c.).

Piccadilly. See LONDON.

Piccolo. FLUTE.

Piccolo'mini, an old and distinguished family of Italy, settled at Siena, who subsequently obtained possession of the duchy of Analfi. It produced numerous celebrated *littérateurs* and warriors, one pope (Pius II.), and several cardinals. One of the most illustrious members of this family was OTTAVIO, Duke of Analfi, born in 1599. He entered the Spanish military service, and, being sent to aid the Emperor Ferdinand II., fought against the Bohemians at the battle of the Weissberg (1620), then in the Netherlands, and after that in Wallenstein's army at Lutzen (1632). He was one of the chief agents in effecting the fall of the all-powerful general, by betraying his secrets to the emperor. Then he greatly distinguished himself in the battle of Nordlingen (1634). In the following season he was sent to aid the Spaniards in the Netherlands, and speedily drove out the French, but had not much success against the Dutch. He was withdrawn by the emperor in 1640 to stay the Swedes, who, under Banér, were threatening the hereditary possessions of Austria. This purpose he accomplished; but, though he was successful against these northern invaders in the Palatinate, he was worsted in Silesia by Torstenson. Returning to the Spanish service in 1643, he was sent again to the Netherlands to take the command of the Spanish troops. But his success was not nearly so decisive as before, the prestige of the Spanish infantry having been destroyed by Condé at Rocroi (1643). After the signing of the peace of Westphalia (1648) Piccolomini was created a field-marshal by the emperor, and was sent as plenipotentiary to the Congress of Nuremberg (1649). He died at Vienna, 10th August 1656, leaving no children; his son Max, who figures in Schiller's *Wallenstein*, is only a poetical fiction.

Pic du Midi, a summit of the Pyrenees, 9466 feet high, in the south-east corner of the French department of Basses-Pyrénées.

Pichegru, CHARLES, French general, was born a labourer's son at Arbois in Jura, 16th February 1761, and was educated by the Minorite friars at Arbois and at the college of Brienne. He enlisted into an artillery regiment in 1783, and showed such capacity and courage on the Rhine in the fiery service of the young republic that by 1793 he was a general of division. In October of that year he was given supreme command on the Rhine, and in conjunction with Hoche and his army of the Moselle he drove back the Austrians, relieved Landau, and overran the Palatinate. Next year he continued his career of triumph in the Netherlands, and showed in three campaigns within one year consummate generalship and a fortunate audacity worthy of the great Napoleon. After by swift movements defeating the Austrians in detail, he broke their forces at Fleurus, June 27, 1794, and, continuing the struggle into the winter, crossed the Meuse and the Waal on the ice, entered Amsterdam, January 20, 1795, and soon occupied the whole of Holland. During this campaign occurred the famous capture by the French hussars of the Dutch ships frozen in the Helder. Recalled to

Paris by the Thermidorians, the 'Sauveur de la Patrie' crushed an insurrection of the *faubourgs* at Paris, 1st April 1795, next proceeded to the Rhine, and took Mannheim. But at the height of his fame he turned traitor, and sold himself for vast promises to the Bourbons. With deliberate treachery he remained inactive before the enemy, and allowed Jourdan to be defeated. The Directory becoming suspicious suspended him by Moreau, and Pichegru retired to Arbois. In 1797 he took his place, first as member, next as president, of the council of Five Hundred, and continued his Bourbon intrigues, but on the 18th Fructidor (4th September) was arrested and deported to Cayenne. Escaping in the June of next year, he made his way to London, was attached to the Austro-Russian army in 1799, and thereafter lived in Germany and England until the formation of the Bonrbon conspiracy of Georges Cadoudal (q.v.) for the assassination of the First Consul. The pair reached Paris secretly, but found it impossible to gain over Moreau. They were soon betrayed to the police, and Pichegru was seized in bed and carried to the Temple, 28th February 1804. Here, on the morning of the 6th April, it was found that he had anticipated justice, and ended his dishonoured life with his own hands. There is no justification for the royalist slander that he was made away with by Napoleon.

Pichichiago. See CHILAMYDOPHORUS.

Pichincha ('boiling mountain'), the most populous province (210,000 in 1922) of Ecuador, embraces the Quito plateau and its slopes. Area, 8300 sq. m. The soil is fertile in the west. The province takes its name from the active volcano of Pichincha, 8 miles NW. of Quito, the chief town. It has five peaks, two of which (15,918 feet) Edward Whymper ascended in 1880. The enormous crater, nearly a mile across at the top and perhaps 1500 feet in diameter at the bottom (which is 2500 feet below), is said to be the deepest in the world.

Pichler, KAROLINE, novelist, was born 7th September 1769 at Vienna, her maiden name being Groiner; and between 1800 and her death, 9th July 1843, published novels and dramas sufficient to fill a collected edition of 60 volumes, of which the most notable are *Agathokles* (1808), *Frauenveride* (1808), *Die Belagerung Wiens* (1824). Her autobiographical *Denkmürdigkeiten* (1814) fill 4 vols.

Pickercel. See PIKE.

Pickering, a market-town in the North Riding of Yorkshire, 27 miles NNE. of York. It has a fine ruined castle, which was Richard II.'s first prison and was dismantled by the Roundheads, and an interesting parish church. Pop. 3500.

Pico. See AZORES.

Pico della Mirandola, GIOVANNI, one of the most curious figures in the history of the Renaissance, was born in 1463, the son of Francesco Pico, Count of Mirandola and Concordia in the Modenese. He was a wonderfully precocious boy, and in his youth he made a round of the chief universities of Italy and France. In 1486 he challenged all comers to public discussion at Rome, but the debate was forbidden by the pope on the score of the heretical tendency of certain of the nine hundred theses which Pico offered to maintain. His *Apologia* exposed him to considerable persecution until Alexander VI. in 1493 absolved him of the charge of heresy. He spent much of his life in travelling, and became known as a generous bene-

factor of the poor. He was an intimate friend of Politian and Lorenzo de' Medici. He died of fever in 1494, and Savonarola, who had been anxious to enrol him among the Friars Preachers, vested him after death in the habit of the order. Mirandola was the last of the schoolmen. He endeavoured to reconcile the Catholic theology with medieval philosophy, and his works are a bewildering compound of mysticism, scholasticism, and recondite knowledge. He interpreted the Mosaic text by the Neoplatonic doctrine of the microcosm and the macrocosm, and maintained that in natural magic lay the strongest testimony to the truth of the Gospels. He appealed to the authority of the Cabbalists and Pythagoreans as well as to the Apostles; he exhibited, along with a childlike credulity, an argumentative ingenuity worthy of the subtlest schoolman. He was a humanist as well as a theologian, and was the author of various Latin epistles and elegies and of a series of florid Italian sonnets. His writings are of little value, but the magic of his personality survives. A theologian and an erotic poet, a philanthropist, a scholar, and a traveller, an adherent at once of Duns Scotus and of Politian, he was one of the most chivalrous, generous, and versatile of men; his character is as engaging as it is curious and complex.

See *G. P. della Mirandola*, his life by his nephew (1496; trans. by Sir Thomas More, 1510; ed. J. M. Rigg, 1890), and Faber's *Studies in the Renaissance*.

Picotee. See CARNATION.

Picquet. See PIQUET.

Picric Acid (Trinitrophenol), $C_6H_2(NO_2)_3OH$. This substance appears in the form of pale yellow crystalline scales. It is obtained by the action of nitric acid on phenolsulphonic acid. Equal parts of phenol and concentrated sulphuric acid are mixed together, and placed in a suitable vessel, which is heated till the mixture reaches $212^\circ F.$ ($100^\circ C.$). Nitric acid of the specific gravity 1.3 is then added. On cooling, a crystalline mass is produced which is filtered and drained, washed, and purified by recrystallising. Picric acid is easily soluble in hot but only slightly in cold water. It is also soluble in alcohol and ether. Its taste is intensely bitter, and its power as a yellow dyestuff is very great. It has been much used for dyeing silk, wool, and leather. As it does not adhere by itself to vegetable fibre, it serves for a test to distinguish cotton from wool or silk. The presence of cotton in a mixed fabric can therefore be detected by steeping it in a hot solution of the acid and afterwards washing it. It was formerly called Carbazotic Acid. The salts of picric acid form powerful explosives; and, since 1885, on Dr Sprengel's discovery that the acid itself is a very powerful explosive when detonated, the acid alone, or modified by the addition of oxidising material to combine with the slight excess of carbon which is the result of its detonation, has been used as the basis of blasting-charges for shells, for which it is peculiarly well suited owing to its comparative insensitiveness to shock. It is the basis of lyddite, melinite, shimose, and other explosives of this class. The objection to it is the readiness with which its salts (picrates) are formed, some of them being exceedingly sensitive explosives. This is notably the case with lead, the picrate of which approaches fulminate of mercury in sensitiveness. In the manufacture, therefore, of picric acid for warlike purposes, extraordinary care has to be taken that the ingredients of which the acid is made should be pure, and that subsequently it shall be kept from contamination. Picric acid was added to the British Pharmacopœia in 1914. For references see under DYNAMITE.

Picrite, an ultrabasic plagiocrystalline igneous rock, differing from Peridotite in containing a small amount of felspar (usually labradorite). The dominating ferromagnesian minerals are augite and olivine. Biotite, iron ores, and apatite are common accessories. The rock is often more or less altered into serpentine.

Pictet, ADOLPHE (1799-1875), a native of Geneva, and a writer on the Celts and the primitive Aryans. To the same Genevese family belong Marc-Antoine Pictet (1752-1825), physicist; François Jules Pictet (1809-72), zoologist and paleontologist; and Raoul Pictet (b. 1842), chemist and physicist, known in connection with the liquefaction of oxygen.

Picton, SIR THOMAS, British general, was born in August 1758 at Poyston in Pembrokeshire, entered the army as ensign in the 12th Foot in 1772, and two years later joined his regiment at Gibraltar. In 1794 he went out to the West Indies, and was given a command under Sir John Vaughan. He took part in the conquest of several islands of the West Indies, including Trinidad, and was appointed (1797) governor of the last named, being shortly afterwards raised to the rank of general. In 1803 he was unpetsed, but immediately after appointed governor of Tobago. He found it necessary, however, to return to England, to take his trial on a charge of having permitted, under the old Spanish laws, a female prisoner to be tortured. He was found guilty of sanctioning unlawful torture; but on appeal he was in a new trial acquitted. He saw active service again in the Walcheren expedition (1809), and was made governor of Flushing after its capture by the English. Early in the following year he was summoned to Spain, and put in command of the 'Fighting Division,' and with it rendered brilliant service at Busaco, during the subsequent expulsion of the French from Portugal, at Fuentes d'Oñoro, at the sieges of Ciudad Rodrigo and Badajoz, at Vittoria and in the battles of the Pyrenees, at Orthez and before Toulouse. Napoleon's escape from Elba once more called Picton into the field; he fought at Quatre Bras and was wounded, but kept the fact hidden that he might not miss the great day he saw coming, and he fell leading his men to the charge at Waterloo, 18th June 1815. See *Memoirs of Sir T. Picton*, by H. B. Robinson (2 vols. 1835).

Picton, a port of entry on the north coast of Nova Scotia, on a splendid harbour, 85 miles NNE. of Halifax. There are iron, lumber, leather, flour, and other industries, but coal, mined in the vicinity and largely exported, is the leading interest. Pop. 3000.

Picts. This is the name by which, for five and a half centuries (296-844 A.D.), the people that inhabited eastern Scotland from the Forth to the Pentland Firth were known. In the Irish chronicles they are generally styled Picti, Pictoune, Pictoures, or Piccadraig—all forms of the same root; but sometimes the native Gaelic name of Cruithnig or Cruithnig also in Ireland—never, however, called Picti. They formed the petty kingdom of Dalriada (County Down and part of Antrim) and bordered on the Irish Dálriada; and, as the kingdoms of both these provinces were contemporary with the whole extent of Pictish rule, much confusion is thereby caused as to what refers to Scots and what to Irish Cruithnig in the annals. Other Irish Cruithnig appear sporadically, not to say enigmatically, in Meath and Roscommon. There does not seem to have been any difference in language

and customs between these Irish Cruithnig and the rest of the people of Ireland, at least in historic times. They were probably early invaders from Britain belonging to the Pictish race.

The Picts are first mentioned in connection with the campaigns of Constantine Chlorus in Britain in 296 and 306. Eumenius, his panegyrist, speaks of 'Caledonum aliorumque Pictorum silvas et paludes' (the Caledonians and other Picts), which implies the inclusion of the former in the latter people. Caledonia is the name given by Tacitus to Scotland north of the Firths of Forth and Clyde, and he describes the Caledonians as a noble race of barbarians, who fight in chariots as well as on foot, with long swords and short shields, and whose fair red hair and large limbs argued a German origin. Ptolemy (120) places fourteen tribes in Tacitus's Caledonia, inclusive of the Caledonians themselves, and the more easterly ten of these may be claimed as Picts. So troublesome were these northern tribes to the Roman province that in 208 the Emperor Severus came to Britain and vainly attempted their subjugation. The contemporary historians mention only two tribes north of the Forth and Clyde wall—the Maer and the Caledonii—and Tacitus's noble barbarians appear in their pages but squalid savages, having no cities, knowing no agriculture, possessing wives in common, and tattooing their bodies with pictures of all kinds, to show which 'they wear no clothing,' says Herodian. Yet they have chariots and weapons as described by Tacitus, with dagger and peculiarly knobbed spear. One hundred years later the Caledonians and other Picts, as already said, are encountered by Constantine, and still fifty years later they are harassing the Roman province (360) now in company with the Scots, who are first mentioned at this date, and who appear as great sea-wanderers, starting from Ireland and Scotland both, it would seem, and attacking the whole seaboard of the province, especially Wales. The Picts and Scots are helped in this 'continual vexing' of the Britons by the Saxons and Atacotti. The Picts are represented at this time as divided into two nations called Dicalidona and Vecturiones, or rather Vecturiones, to accept Sir John Rhys's happy emendation of Ammianus's text, for this latter form may be identified with the historic Fortriu (Stathenus and Meith). Theodosius the elder in 369 subdued these northern foes and restored the district between the walls to Roman Britain, and the usurper Maximus signalled his assumption of power in 383 by an energetic campaign against the Picts and Scots. During the next quarter of a century the Romans were losing their hold on Britain, and their northern foes pressed on the province with great persistence. First the northern wall was rebuilt, then abandoned; and lastly the southern wall was repaired by the last legion sent. In vain did the brave Stilicho gaze on the 'figures fading on the dying Pict,' as Claudian says, for they burst on the Romanised Britons with more fury than ever, and the calling in of the Saxons against the Picts and Scots made the last state of the Britons worse than their first.

At this point the light of Roman history is withdrawn from us, and we have to depend on vague references in native writers—on Gildas of Wales (6th century), on Adamnan (704), on Bede (731), on Nennius (9th century), and on the Irish and other annalists of the middle ages, the best of whom is Tigernach (1088). There is a Pictish Chronicle, perhaps composed in the 10th century, but preserved only in a MS. four hundred years later in date. Gildas describes the Picts and Scots as 'differing somewhat in manners,' and 'shrouding their villainous faces in bushy hair rather than

clothing' their lower limbs. Bede points out that the Picts are divided into a southern and a northern division by the Grampians. The southern Picts were converted to Christianity by St Ninian (*circa* 400), and the northern Picts over a century and a half later by St Columba. Bede also notes and mythically explains the system of succession among the Picts, whereby the reigning monarch was succeeded not by his son but by either his brother or his sister's son, descent being counted through the females. This curious rule is amply confirmed by the Pictish list of kings. Scotland in Bede's time, and for more than a century previously, was divided among four nations: the Saxons and Britons were south of the Firths, and north of them were the Picts east of Drummalban, and the Scots to the west with Dalriada or Argyllshire as their head centre. The annals say little of the Isles and north-west coast, whether they were held by Scots or Picts, though subsequent history makes it clear that the Scots had long colonised them, for the sons of Ere in 501 were but the last of many Scottic invaders and colonisers. That the four nations of Bede's day spoke four different languages is clear from his oft-repeated statement to that effect, and his handing down a word in this Pictish tongue (*praufrithel*). Columba, according to Adamnan, had to employ an interpreter twice in dealing with the Picts, while Cormac of Cashel mentions a word (*carthi*) belonging to the *berla cruthnech* or Pictish language.

In the ninth year of the reign of Brude MacMailchon, the year 563, Columba landed in Scotland to convert the Picts. Brude had his royal residence near Inverness, and was 'a most powerful king,' Bede says, for he represents him as granting Iona to Columba, though Tigernach says that Connal of Dalriada made the gift. But the Picts were carrying on war among the Isles at the time, as the life of St Congall shows, and Brude had hostages from the king of the Orkneys. Brude's successor, Gartnait, seems to have fixed his capital at Abernethy, the church of which he founded. The Picts were subjugated by Oswald, king of Northumbria, and made tributary by his brother Oswin after 654. They remained under the Anglian yoke for thirty years; but Brude, son of Bile, asserted his rule among the northern Picts, and meeting the Anglian king Egfrid at Dunnichen in 685 defeated and slew him, and thus ended the Anglian rule over the Picts. About 710 Naiton or Nectan, son of Deuille, was king of the Picts, and, as Bede tells us, he conformed under Anglie influence to the Roman Church in regard to the celebration of Easter, going indeed so far as to expel recalcitrant Columban clerics across Drummalban. Following a custom not unfrequent at the time, Nectan resigned his throne and became a cleric. A fierce struggle ensued for the throne, during which Nectan emerged from his monastery, but eventually Angus, son of Fergus, petty king of Fortrenn, crushed all his rivals and reigned for thirty years, when this 'sanguinary tyrant' died in 761. His brother Brude died king of Fortrenn in 763, for evidently Angus's monarchy had collapsed and the provincial kings again came to the front. Unfortunately the next eighty years of Pictish and Scottish history are exceedingly difficult to unravel, for lists of kings and a reference or two in the Annals of Ulster are all the material which is to hand. Ciniad was king after Brude, but his rights were disputed by Aed of Dalriada; and after his death in 774 there is much confusion in the Chronicles, as there must have been in the facts. Dalriadic princes struggle with Pictish princes and with one another for the throne, till Constantine of Dalriada established himself about 815 as king over both. His and his brother's reign ended in

834, and a time of confusion followed, native Pictish princes striving against Eoganau of Dalriada, and he ultimately succeeding. The year 839, which ended his reign, saw a great defeat and slaughter of the Picts by the Danes, with confusion once again, from which emerged in 844 Kenneth MacAlpin, the Scot, as king over both nations, henceforward not to be disunited. Many things contributed to the overthrow of the Pictish kingdom, such as it was, and of the Pictish language: the disunion, physical and otherwise, between northern and southern Picts; the rule of female succession which allowed Anglie, Briton, and Scottic princes to rule in right of their mothers, with the consequent degradation of marriage which matriarchy implies; and the superior culture of the Scots, Christian and literary. Nor must it be forgotten that we really do not know much about the Isles and west coast north of Argyll, nor indeed of the counties north of Inverness, from the time of Brude MacMailchon till the Norsemen came. It is quite certain that the Scots colonised these very early, and had, indeed, established themselves in Perthshire. Aidan, the son of Gubhuan, makes expeditions to Orkney, and fights the Picts and defeats them on the Forth, or even further eastward, in Moarns. This aggressive energy, combined with the other facts of the situation above enumerated, would easily enable the Scots to supersede the Picts in power and language.

The real 'Pictish question,' however, is what the language was which they spoke. This question must not be confused with another if allied one, What race did the Picts belong to? The Picts may have spoken a Celtic language though racially possessed of little Celtic blood, and may have retained non-Celtic customs as survivals of a lower culture, as indeed they did in the case of female succession. Four hypotheses have been formed in regard to the language and origin of the Picts. The first, started by Pinkerton and put by Sir Walter Scott into the mouth of the 'Antiquary,' is that they were Teutons, speaking a Gothic dialect; the second, maintained by Dr Skene, is that they were Gaelic-speaking Celts, and that they and not the Scots finally conquered in the 9th century; the third, due to Sir John Rhys, is that the Picts were not Indo-Germanic, but that their language was overlaid by loans from Welsh and Irish; and the fourth, which was held by two of the most eminent of Celtic scholars, Professor Windisch and Dr Whitley Stokes, is that they were Celts, but more nearly allied to the Cymry than to the Gael.

The materials for deciding the linguistic relations of the Picts, though fairly abundant, consist almost entirely of names—those in the classical writers, in the king lists, and in the Book of Deer, and the still or lately existent place-names of ancient Pictavia. The main agreement between the Gallo-Cymric and Gaelic languages is their dropping of Indo-Germanic initial *p*; their main difference is their developing the labialised guttural *qu*—Gallo-Cymric (like Ossani) into *p*, and Gaelic (like Latin) into *q* or *c*. This fact led Sir John Rhys to call them respectively *P* Celts and *Q* Celts. No native initial *p* exists in old Gaelic language. The name Picti, which was usually regarded as the Latin for 'painted men,' is now considered inseparable from Pictones or Pictavi of Gaul, now Poitou, and is therefore Celtic of the *P* group. An old Gaelic equivalent is supposed to exist in *cicht* ('engraver'), which leaves the old idea of 'painted or pictured men' intact. Further, the Gaelic name *cruthni* is derived from *cruth* ('form, figure'), Welsh *pryd*; and the Welsh name for Pict is actually Prydyn. The form Pretannia, undoubtedly used by the best Greek writers for

the Latin Britannia, makes it possible that the Crutnigh gave their name to Britain. The meaning of Bede's Pictish word *peannfahel* is practically explained by himself as Wall's Head, where *peann*, with its *p*, answers to Welsh *pen* ('head') and not to Gaelic *ceann*. Similarly *Pern* and *part* in the king lists belong to the P group; but more striking still is the *petl* of the Book of Deer, which signifies 'a portion of land,' corresponding to Welsh *petl*, and etymologically to Gaelic *cuit* ('portion'). *Pet* or *put* is a prefix in place-names in Pictland from Sutherlandshire to the Forth at the present day, some two hundred being easily counted, though the Gaelic *Bal* has considerably extruded it in western Pictland. Minor points in the phonetics of the Pictish names are the preservation of *et* and *ut* as in Cymric; *ch*, as in Ochil, Welsh Uchel, but Gaelic Uasal; *it*, in Naiton, for Gaelic Nectan, being Cymric; Elphin for Alpin or Albin; Bridei for Brude, where *u*, as in Welsh, changes to *i*; the Cymric forms of the prefix *wr* or *wer* for Gaelic *for* or *fer*; and others. Names like Talorg and Morennu remind us of Gaulish Argio-talus, 'silver-brow,' and of Welsh Morgan. Modern place-names like Dee ('goddess'), Don for Divoua ('goddess'), Tay, Eden, Nith or Nethy, and Ythan can hardly be paralleled outside Gallo-Cymric ground. The *sp* of Spey and Spean is evidence of non-Gaelic origin. Dr Whitley Stokes, who collected all the extant Pictish words from Tacitus down to the mediæval annalists in 'On the Linguistic Value of the Irish Annals' (*Transactions of the Philological Society*, iii. 1889-90), sums up the philological arguments with sufficient temperateness thus: 'The foregoing list of names and other words contains much that is still obscure; but on the whole it shows that Pictish, so far as regards its vocabulary, is an Indo-European and especially Celtic speech. Its phonetics, so far as we can ascertain them, resemble those of Welsh rather than of Irish.' The conclusion to which we come is that the Picts, whatever traces they show of an alien racial element, with its consequent survival of lower ideas of marriage-laws, spoke a Celtic language belonging to a branch of Celtic allied to Cymric, but dialectically different from the Welsh of Bede's time; and that this dialect of the Gallo-Cymric stock was a wave of Celtic speech from the Continent previous to the Gaulish which held England when Cæsar entered Britain.

See Skene's *Chronicles of the Picts and Scots* (1867), and his *Celtic Scotland*, vol. I. (1886); Rhys's *Celtic Britain* (1884, and later editions), his Rhind Lectures for 1889 in the *Scottish Review*, and, with Brynmor Jones, his *The Welsh People* (1900); Stokes's study above mentioned; Windisch's article, 'Keltische Sprachen,' in Ersch and Gruber's *Encyclopædie*; Macbain's *Etymological Dictionary of the Gaelic Language* (1896, 2d ed. 1911); Nicholson's *Celtic Researches* (1904); Scott's *The Pictish Nation* (1918); Adamson's *Columba*; Hennessy's *Annals of Ulster* (1887); Bede's *Ecclesiastical History* and the other documents in the *Monumenta Historica Britannica*; Innes's *Critical Essay* (1729; new ed. 1879); and Pinkerton's *Inquiry into the History of Scotland*.

Picts' Houses, the name popularly given in many parts of Scotland to the rude underground buildings, more commonly and accurately called Earth-houses (q.v.). The Brochs (q.v.) are also sometimes called Pictish Towers.

Piedmont (Ital. *Piemonte*; Fr. *piéd*, 'foot,' *mout*, 'mountain'), a former Italian principality, which now forms the north-west part of the kingdom of Italy, is by the Alps separated from Switzerland on the N. and from France on the W.; on the E. lies Lombardy, and on the S. Liguria and Genoa. It included the duchy of Monferrat and part of the old duchy of Milan, and now embraces the provinces of Alessandria, Cuneo, Novara, and Turin, and covers 11,330 square miles, with a population of 3,384,000. For an account of its geographical features, see ITALY. From the end of the 12th century the name Piedmont was used as a collective title for the territories ruled over by the House of Savoy on the east side of the Graian and Cottian Alps; the history of the region will be found under ITALY, SARDINIA, SAVOY, and WALDENSES. See, too, S. Butler's *Alps and Sanctuaries of Piedmont*.

Piepowder Court, in England, an ancient court held in fairs and markets to administer justice in a rough and ready way to all comers, called also the Court of Dusty Foot (Old Fr. *piepoudrre*). Its jurisdiction seems to have been confined mostly to petty vagabonds, pedlars, and other wanderers. The court has long been obsolete, its jurisdiction merged in the court of Petty Sessions (q.v.).

Pierce, FRANKLIN, fourteenth president of the United States, was born at Hillsborough, New Hampshire, November 23, 1804. His father, Benjamin Pierce, a farmer who had risen in the war of independence to the rank of major, in 1827 and 1829 became governor of New Hampshire. Franklin Pierce was educated at Bowdoin College, and was an officer in a college military company, in which his biographer, Nathaniel Hawthorne, was a private. He graduated in 1824, studied law, and was admitted to the bar in 1827. From 1829 to 1833 he was a member of the state legislature, and for two years was its speaker; he was then elected to congress, a Democrat of the school of Jackson. In 1837 he was elected to the United States senate, of which he was the youngest member. In 1842 he resigned his seat, and returned to the practice of law. He refused the Democratic nomination for governor, as well as an appointment to fill a vacancy in the senate; and he declined the office of attorney-general offered him by President Polk. He remained, however, among the leaders of his party, zealously advocated the annexation of Texas, with or without slavery, and, after his opponents, the Whigs and Free-soilers, had been victorious at the polls in 1846, volunteered as a private for the Mexican war. The president made him a brigadier-general, and in August 1847 he joined General Scott, and led his brigade in the battles of Contreras and Churubusco. In 1852, in consequence of the conflicting claims of the leaders of the Democratic party at the Baltimore Convention, he was nominated as a compromise candidate for the presidency, against General Scott, the Whig nominee, and received the votes of all but four states. President Pierce in his inaugural address defended, on constitutional grounds, slavery and the Fugitive Slave Law; and his cabinet, which was an eminently able one, included Jefferson Davis as secretary of war. Pierce's view as to slavery was that it was the price paid for the Union by the framers of the federal constitution, and that, therefore, in honesty it must be maintained. The principal events of his administration—in importance far before the treaty for reciprocity of trade with the British American colonies and the treaty with

Japan, or the filibustering expeditions of Walker (q.v.) to Nicaragua and of others to Cuba, with the resultant abortive Ostend (q.v.) Manifesto—were the repeal of the Missouri Compromise (see MISSOURI) and the passing of the Kansas-Nebraska Act (see KANSAS), which kindled a flame of civil war in the new territory that ultimately set the whole Union in a blaze. Pierce, with his rigid regard for constitutional obligations, was intensely hostile to the free-state settlers and to abolitionists in general. At the close of his term of office in 1857 he spent three years in Europe; and afterwards, having no sympathy with the party which subsequently came into power, he took no part in politics. He died at Concord, 8th October 1869. As a lawyer Pierce was an eminent and eloquent pleader; as a statesman his administration would have passed for skilful and successful had it not been for the slavery storm which rose and wrecked it; while as a man he was amiable and generous, and of spotless integrity. There are *Lives* by Hawthorne (1852) and D. W. Bartlett (1852), and Ireland's more critical *Life, Administration, and Times of Franklin Pierce* (vol. xiv. of his *Republic*, 1887, &c.).

Pieria, a coast district of ancient Macedon, at the base of Olympus, and between the Peneus and Ilhacmon. It was the fabled birthplace of the Muses and of Orpheus.

Pierre, the capital of South Dakota, is a small town in the centre of the state, on the Missouri River, at the mouth of Bad River, 781 miles by rail WNW. of Chicago; pop. 3000.

Pierson, HENRY HUGO, composer, was born (Henry Hugh Pearson) at Oxford in 1815, in 1844–45 filled the chair of Music in Edinburgh, and from 1846 lived in Germany, dying at Leipzig, 28th January 1873. Among his works were the music for the second part of Goethe's *Faust*, the operas *Leila* and *Contarini*, and the oratorios *Jerusalem* and *Hezekiah*.

Piers the Plowman. See LANGLAND.—*Pierce the Ploughman's Creed* is a poem of similar character by another hand, dated about 1394 by Skeat, who edited it (1867 and 1906); and there were other imitations.

Pietà (an Italian word signifying *piety*, in the sense in which that term indicates or includes affection for relatives), the name given in art to representations of the Virgin Mary embracing the dead body of her son. It is a counterpart to the *Madonna* with the infant Jesus in her arms.

Pietermaritzburg, or MARITZBURG, capital of Natal (q.v.), occupies a fine situation near the Umsundusi River, 50 miles NW. of Durban, and 2218 feet above sea-level. The town is well laid out, and has some good buildings. It is built, in Dutch fashion, on the plain, though there are hills close by, among which the Town Hill is notable. Port Napier overlooks the city from a hill on the south-west. Pietermaritzburg has a university college, library and museum, asylums, a park, botanical gardens, &c. It takes its name from its founders (1839), the Boer leaders, Pieter Retief and Gert Maritz. There is railway connection with Durban, with the Orange Free State, and with Johannesburg and Pretoria in the Transvaal, &c. The place has steadily increased in importance with the development of the railways. Pop. (1887) 15,767; (1921) 36,023—17,998 whites, the rest Kaffirs and Indian coolies.

Pietists, a designation given at the end of the 17th century to a religious party in Germany, which, without forming a separate sect, was distinguished rather by fervour and zeal than by peculiarities of religious opinion. See CHURCH

HISTORY, the articles on SPENER and FRANCKE, and the Histories of Pietism by Heppe (1879) and Ritschl (1880–86).

Pietra-dura, a name given to the finest kinds of Florentine mosaic-work, in which the inlaid materials are hard stones, such as jasper, carnelian, amethyst, agate.

Piezometer (Gr. *piezō*, 'I press,' *metron*, 'a measure'), an instrument for measuring the compressibility of fluids, by observing the extent to which an air-bubble which marks the upper level of liquid in the capillary neck of a flask is depressed by the application of an external pressure acting through liquid surrounding the flask.

Pig, or HOG (*Sus*), a genus of artiodactyl ungulate mammals, of the family Suina (see BOAR, where the characteristics of the wild species are discussed, with an illustration). The term Swine is commonly applied to the genus in Britain. The body is covered more or less with bristles and hairs; the skin is very thick; the limbs short and stout; the neck, which is carried straight forward from the trunk, is very thick and strong; the face moderately prolonged and truncated, always terminating in a movable cartilaginous disc, furnished, as in the mole, with a special small bone, and employed with wonderful expedition in turning up the soil in search of roots and other food. In most of the improved varieties the face is much shorter than in the wild boar or ancient pig. There are six incisors, two canine teeth, and fourteen molars in each jaw, the lower incisors projecting forwards; the canine teeth long and strong, projecting and curved, becoming formidable tusks in wild boars, and large and powerful even in the females in a wild state. The feet have each four toes, the lateral ones small, and scarcely touching the ground, all separately hoofed. The tail is short. The stomach shows mere traces of division. The food is chiefly vegetable, but perhaps no animals may more properly be called omnivorous; and although, even in a wild state, pigs are not to be reckoned among beasts of prey, they not unfrequently, even in domestication, kill and eat small animals that come in their way, as many a housewife has had occasion to observe in respect to chickens. The Common Pig (*S. scrofa*) appears to be a native in the wild form (see BOAR) of most parts of Europe and Asia; the domestic European breeds are apparently descended from the European wild boar, crossed with domesticated Asiatic breeds. Like the hippopotamus, to which it is allied, the pig delights in humid and shadowy places. The pig usually grows until five years old. Its natural life ranges from fifteen to thirty years. Although the use of its flesh was prohibited to the Jews, and the prohibition has been adopted in the Mohammedan law, the pig has been a domesticated animal from a very early period, and its flesh constitutes a large part of the food of many nations. The fecundity of the pig is great; with proper treatment it will produce two litters annually, generally of six to eight pigs each, although sometimes there are as many as sixteen or more in a litter. Vast quantities of the flesh are consumed in various forms, as pork fresh or salted, bacon, ham, &c. Brawn (q.v.) is an esteemed luxury. The fat of the pig, which is produced in a thick layer under the skin, is an important article of commerce, and of various use under the name of Lard (q.v.). The skin of the pig is made into leather, which is particularly esteemed for saddles. The bristles, especially of the wild boar, are much used for brush-making. Indeed, there is no food-producing animal which is of greater benefit to mankind than the pig.

There are numerous varieties of the domestic pig. Some have erect and some pendant ears, and those are most esteemed which exhibit the

Improved Yorkshire Pigs.

greatest departure from the wild type, notably in shorter and less powerful limbs, less muscular and more rounded forms, wider ribs and greater wealth of flesh. The *Churse* breed and the *Neapolitan* have been of great use in the crossing and improving of the breeds commonly reared in Britain, giving rise to the improved white and black breeds respectively. The Chinese breed was renowned for its fertility, as well as for the rapidity with which, without materially increasing in offal or bone, it laid on flesh. Its head was short and thick, ears erect, legs very short, chine high and broad, and jowl wide, belly hanging very near to the ground. As a rule it carried a small quantity of hair. The skin was usually dark, but the flesh was delicate and white. These valuable characteristics distinguish the improved Yorkshire pigs which are now so much esteemed all over the British Isles as well as in several foreign countries. The Neapolitan breed was entirely black, with little hair, moderately short in the face, ears small and erect, short in the leg, moderately long and thick in the body, remarkably easy to fatten, but scarcely so robust in constitution or so prolific as the Chinese pig.

There are now twelve distinct improved breeds of swine reared in the British Isles. The Large White or Large Yorkshire is a hardy, prolific and useful white breed, which is the most widely distributed and the most numerously represented. It is of medium length of face, and the nose is not upturned as in the next breed mentioned. It is a good general-purpose type for British conditions, though somewhat late in reaching maturity. The Middle White breed, of smaller size, is more easily fattened at an early age, though somewhat less prolific. The Lincoln Curly-Coated White breed is another large variety, with drooping ears and curly hair. The Large Black breed, of a sooty black colour throughout, and also with lop ears, is of the same general type. The Berkshire is a smaller, less prolific type, black with white 'points,' which is excellent for the production of young porkers, but liable to get too fat when kept to greater age. The Tamworth, a chestnut-coloured animal, is of large size, rather stronger in bone than the other sorts, and is noted for its high proportion of lean meat and the excellent quality of its bacon. It is a prolific but slow maturing type. The Gloucester Old Spot, the Essex, the Wessex, the Ulster, the Cumberland, and the Long White Lop-Eared are breeds of considerable local but of less general importance. In the United States the Berkshire and three breeds that have originated in that country, viz., the Poland China, Duroc Jersey, and Chester White, are the common

varieties. When allowed to run wild, pigs multiply rapidly under favourable conditions, as has happened, for example, in the Polynesian Islands and in New Zealand.

Pigs are profitably kept wherever there is much vegetable refuse on which to feed them, as by cottagers having gardens, farmers, millers, brewers, &c. They are often allowed to roam over fallow ground, which they grub up for roots, and over stubble-fields, which they glean very thoroughly. It was an ancient practice to allow pigs to feed in woods, where they consumed acorns, beechmast, and the like. When they are fed, as is sometimes the case, chiefly on animal garbage, their flesh is less palatable and less wholesome. The pig has a reputation, which it does not deserve, of peculiar filthiness of habits. It is true that it wallows in the mire, to cool itself and to provide itself with a protection against insects, and it searches for food in any puddle; but its sleeping-place is, if possible, kept scrupulously clean. The too common filthiness of pigsties is rather the fault of their owners than of their occupants; and a clean and dry sleeping-place is of great importance to the profitable keeping of pigs.

Hog Cholera or Swine Fever, due to the presence of a bacterium, caused terrible havoc in the United States in 1870-80, though hardly known twenty years before. As in the splenic fever of sheep, due also to bacteria, attempts have been made to ward off the more violent form of the disease by inoculating animals with a milder type.

The pig is not inferior to other quadrupeds generally in intelligence, but it excels most of them in obstinacy. It can be easily rendered very tame and familiar. Its scentness of scent has been turned to account in making it search for truffles; and a tale is told of a pig having been successfully used as a pointer. The pig has sometimes served as a beast of draught.

The *Bosch Vark*, or Bush Hog of South Africa (*Phacochorus*), is about 2 feet 6 inches high, covered with long bristles; it has projecting tusks, a large callous protuberance on each cheek, and long, sharp, tufted ears. It is gregarious, subsists chiefly on vegetable food, and makes destructive inroads on cultivated fields. Other wild pigs are *Sus vittatus* (East and Southern Asia), *Sus veruucosus*, and the *Babiroussa* (Celebes and Bunu). The *Peccaries* (q.v.) are closely allied.

See *Pigs*, by Sanders Spencer (Vinton & Co.), also works by Long and Day.

Pigeon (Ital. *pigione*, *piccione*, or *pipuone*, from *pipiare*, Lat. *pipire*, 'to peep or cheep'), a name sometimes applied, like dove, to all the species of Columbidae, and sometimes almost restricted to those still included by ornithologists in the genus *Columba*; having a bill of moderate length, hard, and a little arched at the point, the base of the upper mandible covered with a soft thick skin, in which the nostrils are pierced; the feet with toes divided to the base, and fanned both for walking and perching; the wings rather large and pointed; the tail of moderate length, and generally square at the end. The species of this group are very numerous, there being nearly 150 different kinds, and they are found in all parts of the world. Some of them build their nests in trees, and others in rocks. They invariably lay only two eggs at a time, but breed several times in the year, both the male and the female taking part in the process of incubation, as also in that of feeding the young birds. The origin of all the domesticated varieties of the pigeon is the Blue Rock-pigeon (*C. livia*), the *Isot* of the French, a bird of extensive geographical range, being found as far north as the Faeroe Islands, and in nearly all parts

of the eastern hemisphere. It is found in large numbers on the British coast, particularly on the Orkney Islands and the Hebrides, and also in the Mediterranean. Its food consists partly of molluscs and other small animals, and partly of grain and seeds; and it often pays unwelcome visits to the cornfields within its radius. In a wild state the blue rock-pigeon exhibits great uniformity both of size and plumage; it is not quite 12 inches in length from the tip of the bill to the end of the tail; the prevailing colour is bluish gray, in some parts with green and purple reflections, and having two broad and distinct black bars across the closed wings; the lower part of the back is whitish; the tail is a deep gray with a black bar at the end; the bill is dark brown; the legs and feet reddish orange. There are also the Stock-dove or Smaller Wood-pigeon (*C.enas*), found all over southern and mid Europe, a species found in woods; and the Ring-dove, Wood-pigeon, or Cushat (*C. palumbus*), very common in all parts of Europe and Asia and in northern Africa, and the largest of the British species. These are all the British species of pigeon. In addition we may mention the Ring-tail Pigeon (*C. caribbea*), a West Indian species; the Bald-pate or White-headed Pigeon (*C. leucocephala*), also found in the West Indies and Florida; the Double-crested Pigeon (*C. dilopha*),

especially many of our most beautiful varieties have been produced. From North Africa we have also received at least one fine breed. Throughout Europe this pursuit is followed with a great amount of enthusiasm, more especially in Italy, Germany, France, and Belgium, as well as the United Kingdom. In Belgium the sport of pigeon-flying or racing is the national sport engaged in by all sections of the community; and to that country we owe the variety known as the Homing Pigeon (see CARRIER PIGEON). In the United Kingdom, as in America, there are enormous numbers of breeders who devote themselves to what are known as 'fancy pigeons,' by which term are known those bred for their special points or characteristics. Of these there is a great and ever-increasing variety, which it is impossible to describe in detail, as there are in all some two hundred breeds, many of which have several distinct colours. The following are some of the most prominent: *Carrier* (q.v.).—This is not, as is commonly supposed, a member of the homing family, though undoubtedly it was at one time used to carry messages. It is much longer in feather than the blue rock, and is specially characterised by having an abnormal development of the beak and eye wattles, the former of which is like a round fleshy ball pierced by the beak. *Dragon*.—Of a similar type, rather lighter in body, and with less heavy wattles. *Barb*.—A heavy-wattled pigeon; but in this case the eye-wattle is the chief point, and it is bled so that the head has the appearance of a bobbin on reel. These three varieties make up the *Wattled Pigeons*; and they are all very valuable when bred to perfection. *Pouters*.—The Pouter Pigeon is equally high class, the name arising from the great development of the crop, which has a globular form, and stands out from the neck. Of these the best known is the English Pouter; and there is also the Norwich Cropper; the former a large bird, and the latter a smaller one. The smallest of this family is the diminutive *Pigmy Pigeon*. In these the head, which is at the back of the crop, is often almost buried by it. *Jacobin*.—A breed in which the head and neck feathers are largely developed, the former in the shape of a hood, so that the head is often buried within it, and the latter falling on to the shoulders, leaving a round space between, known as the rose. *Fantail*.—In this the characteristic which gives the variety its name is that the tail-feathers spread themselves out transversely to the body in the shape of a fan, and in good specimens evenly so. The head is thrown back, often touching the tail, with a nervous motion, the body poised on short legs, and the bird looking as if it were falling backwards. *Tumblers*.—In these the name is derived from the tumbling or turning motion when flying in the air, and good well-trained birds have been known to remain on the wing for many hours without cessation. They are divided into two sections:—viz. Flying Tumblers—i.e. those which are bred for this quality, and Fancy Tumblers, in which the propensity is lost or suspended through disuse. A very valuable breed is the Short and Long Faced Tumbler, of which there are several varieties, notably the Almond, so called from its rich coloured plumage. The Nun and the Magpie are supposed to be descended from the same family. Allied to the flying tumblers are the Rollers and the Tiplers. *Frisled Pigeons*.—These include a very large variety, the greater portion of which originated in the Orient. They are thus called because the throat or chest is decorated with a frill of curled feathers, more or less perfect. Some have in addition a crest on the head, and there is an almost endless variety of colour and of markings, the richest—those known as Oriental Frills—

a, Rock-dove (*Columba livia*); b, Stock-dove (*C.enas*); c, Ring-dove (*C. palumbus*).

found in the northern parts of Australia, and having, as its name indicates, a double crest, one half on the back part of the head, and the other springing from the forehead. There are other species, too numerous to mention.

As already stated, only the blue rock-pigeon has been domesticated, but this species lends itself very readily to the restrictions of civilised life. The changes brought about in it are very varied and remarkable; and the description of his experiments upon the pigeon by Darwin is of the deepest interest. For many centuries and in all lands pigeon-breeding has been a favourite pursuit with all classes of society. In India several of the native rulers have very extensive establishments for the breeding of pigeons. In Persia and in Asia Minor the pigeon is very largely and carefully bred; and in the latter country

being of much later introduction than the Owls and Turbits. One, the White African Owl, is the smallest of all domestic pigeons, and comes from Tunis. *Antwerps*.—A very massive-built bird in which there is a considerable admixture of homer blood. Of the other prominent varieties the homer has already been referred to; the Russian Trumpeter has a large crest and very profuse leg-feathering; the Rant is the largest of all pigeons, and on the continent of Europe is extensively bred for the table.

For the keeping of pigeons different forms of houses may be adopted. When they are permitted to fly about they may have either small cofts for, say, four pairs, mounted on tall poles—and these can be made very attractive—or they may be accommodated in larger houses. Fancy pigeons are usually restrained by what are called flights or aviaries, which consist of a large space attached to the house, the sides and top made of wire-netting, so that the birds cannot get away. It would be too great a risk to permit valuable birds to fly. Whether in confinement or at liberty each pair of pigeons must be supplied with a nest of their own, which is better if double, as often they are sitting on eggs and feeding young pigeons at the same time. In the nest-boxes pans are placed of the usual construction for this purpose. Pigeons are prolific breeders, and will lay several times during the year, each time a couple of eggs. The male and female, if permitted to do so, continue faithful to each other from year to year, a circumstance noted by Pliny and others of the ancients.

Pigeon-flying. See CARRIER PIGEON.

Pigeon-shooting is a form of shooting in which live pigeons are shot at as released from traps. The traps, usually five, are placed 5 yards apart on an arc of a circle which has the shooter, not more than 31 yards off, as its centre. The traps are boxes falling flat open at the release of a spring, so ordered that it is impossible for anyone to know beforehand which bird will be freed; emptied traps are immediately refilled, and at the next word from the shooter the same or any other trap may be released. To count, birds must fall and be retrieved within a boundary from 65 to 20 yards off. As quickest on the wing the blue rock is the pigeon generally used. The sport, as will be seen, is artificial. It is also essentially competitive, and matches are usually for money, sometimes large sums; handicapping is effected by shortening the shooter's distance from the traps. Betting is usual. The merits of pigeon-shooting as a test of marksmanship are undoubted, but the organised nature of the killing, the unfair chance of escape, the incidental cruelties, as of maiming, &c., have tended to bring it, where it has not been suppressed, into disrepute. Pigeon-shooting in England can be traced onwards from 1793. In the days of the Red House, at Battersea, betting was frequently heavy. When the Red House Club was closed in 1850 pigeon-shooting was for some years out of fashion, but later, under Frank Heathcote, many successful meetings were held at the Old Hornsey Wood House. In 1867 the Hurlingham Club at Fillingham was opened, and there pigeon-shooting was a favourite sport; it was, however, stopped on a resolution of the club in 1905. Thereafter meetings took place under the National Gun Club, but in 1921 the sport was prohibited in Britain by act of parliament. Monte Carlo, where pigeon-shooting was instituted in 1872, is the great centre of competitions; prizes are rich, and competitors are attracted from many countries; in 1921 it was promised that live birds would not be used, but in the same year the practice was resumed—only a short distance across the frontier

in French territory. After Monte Carlo, Aix-les-Bains is next in importance.

The substitution of artificial for live birds has given rise to what is known as clay-bird shooting. The 'birds,' of saucer shape, were originally of clay, now more generally of a composition of pitch. They are thrown from traps (usually fifteen) at different and unknown angles. The ordinary distance of an unhandicapped shooter is 18 yards. The sport originated in the United States, and spread to Canada, Britain, France, Belgium, Holland, and elsewhere. In 1893 the Iuanimate Bird Shooting Association, restyled in 1903 the Clay Bird Shooting Association, was formed in England, and under it annual championship meetings were initiated. Throughout Britain there are many clubs.

Pigments used in artistic work vary much in permanence; not a few of the pictures painted by distinguished artists during the 18th and the first half of the 19th century are already more or less faded by the action of light or otherwise injured by impurities in the atmosphere of rooms. It is imprudent to expose any kind of artistic work in colours to direct sunlight or even, it would seem, to the light of electric arc lamps. The following refers to the durability of pigments employed in oil-painting, when continuously exposed to fairly strong daylight. Among blue colours, ultramarine, both real and artificial, is permanent; while Prussian blue is liable to some change, and indigo is fugitive. Among red colours, vermilion and the red ochres are perfectly durable; while the madder reds and purples can hardly be so thoroughly relied upon, and the carmine and crimson lakes, from cochineal, quickly give way. Among the yellows, raw sienna, yellow ochre, as well as the cadmium and Naples yellows, are quite stable; while Indian, chrome, and lemon yellows, and also anacolin, although less so, are yet fairly durable, but gamboge and yellow lake are not. Among greens, oxide of chromium undergoes no change, terre verte is practically permanent, and so also is emerald green, but it is blackened by contact with cadmium yellow. Among browns, burnt sienna, raw and burnt umber, capcagh brown, and Caledonian brown do not at all fade; but hardly as much can be said of madder brown, Cologne earth, and Vandyke brown, although these are fairly durable. Asphaltum or bitumen has a tendency to move on the canvas unless very carefully prepared, and its rich brown colour is not altogether permanent. Lampblack, Ivory black, and charcoal black are quite durable, so also are flake white, zinc white, and baryta white. It is generally the case that a colour produced by a mixture of permanent pigments is also permanent, and it may be added here that flake white (white lead), so much used to mix with other colours for light tints, is liable to discolour when exposed to sulphuretted hydrogen (an occasional impurity in coal-gas), and this colour has also a tendency to tarnish when kept in the dark.

The above remarks on colours made up with oil apply equally to water-colour pigments, with a few exceptions. These are vermilion, especially if artificial, Naples yellow, chrome yellow, and madder brown, the permanency of which cannot be relied upon in water-colours, under which head some further remarks on this subject will be found.

Fuller information about the pigments named above, as well as others, will be found under the heads ASPHALT, BLACK, BLUE, GREEN PIGMENTS, LAKES, OCHRES, &c. The oils and varnishes used as media for pigments, as well as the nature of the prepared canvas or paper used for painting upon, have all a bearing on the preservation of the colours of a picture. See works by A. P. Laurie. The

history of the introduction of the principal pigments is given at PAINTING.

Pigments of Animals. The colour of an animal or part of an animal may be due to the physical structure of the surface from which the light is reflected, as in the case of the mother-of-pearl in the interior of a shell. Or it may be due to the presence of a substance whose molecules absorb or reflect only certain parts of the visible spectrum. Such substances are called pigments, and they vary greatly in their chemical nature. The reddish pigment of the blood, the blackish pigment of dark fur, and the yellowish pigment of yolk of egg may serve as examples. Thirdly, the finest colouration among animals is due to a combination of physical and pigmentary colour, as in the blue feathers of some parrots, the metallic-green wing-cases of some beetles, the beautiful blue scales of some butterflies, and the iridescent scales of Aphrodite, the sea-mouse. When physical structure is a factor the colour of the surface changes as it is moved about, as is familiar in peacocks' feathers; when physical structure enhances the effect of a pigment, it may result in a colour—notably blue or green—which is quite different from the colour of the pigment.

Chemistry of Animal Pigments.—It is convenient to begin with chlorophyll, the green colouring matter of plants, for it is the most important pigment in the world, being connected with the utilising of red and orange light rays in photosynthesis. In the green freshwater sponge, the green hydra, the green sea-anemones, in the green worm called *Convoluta*, and in many other cases, the green colour of the animal is due to partner or symbiotic Algae (*Zoochlorella* and others), but there are also a few green animals, which have chlorophyll of their own. These may be illustrated by the green Bell-Animalcule (*Vorticella nireidis*) and various green Flagellates, such as *Englema* and *Volvox*. The molecule of chlorophyll is still very imperfectly understood, but it is readily split into two parts by the action of alkali, one of the parts being a complex, colourless alcohol called phytyl. The other part has for its foundation the pyrrol ring, in which four carbon atoms form a ring with one atom of nitrogen. In chlorophyll there are four of these pyrrol rings joined together, and linked to these in some way there is a single atom of magnesium. The reason for giving this detail is that a very similar structure recurs in the red pigment of the blood. As a matter of fact the chlorophyll of plants is much more complicated than used to be supposed; it is a system of four pigments, chlorophyll-*a* and chlorophyll-*b*, which absorb red and orange rays, and therefore appear green, and besides these there are two yellowish pigments, carotin and xanthophyll, which seem to be less important. When the light shines on the green leaf, there is probably a continuous cycle of change, from chlorophyll-*a* to chlorophyll-*b*, with absorption of carbon dioxide, and back again from chlorophyll-*b* to chlorophyll-*a*, with liberation of oxygen. This is very interesting, because in the blood of vertebrates the red pigment shows the same general alternation between oxy-haemoglobin and haemoglobin. (See RESPIRATION.)

The molecule of haemoglobin, the red pigment of the blood, may be split into two parts, the colourless portion being a protein called globin. The coloured portion, now called haem, consists (like that of chlorophyll) of four pyrrol rings linked together with an atom of iron. Haemoglobin varies from species to species, but the differences concern the attached protein, not the essential nucleus. In the lungs the pigment in the red blood-corpuscles captures oxygen and forms oxy-haemoglobin; in the tissues oxygen is set free to

supply the needs of the cells. There is a continual breaking down of haemoglobin in the body, and the products, free from protein and iron, are dealt with in various ways. Thus they almost certainly give rise to the bilirubin and biliverdin of the bile of vertebrates, and some are laid down as tissue-pigments in various backboneless animals, such as leeches and molluscs. Allied to haemoglobin, but not so effective, is haemocyanin, a bluish copper-containing blood-pigment, common among invertebrates such as crustaceans, some insects, and most molluscs. Here also a reference must be made to the 'cytochrome' pigments discovered by Keilin in 1925. A cytochrome contains the haem nucleus and is therefore related to haemoglobin, but it is much more widely distributed, perhaps universally. It does not carry oxygen over a distance as haemoglobin does, but probably serves to control oxygen within the cell.

Another series of pigments with a wide distribution is the melanin series. Melanin gives dark colour to skins, as in negroes, to the black feathers of the blackbird, to the dark choroid of the eye, to the ink of cuttlefishes, and in scores of other cases. It always occurs in little granules and it will not crystallise. Its origin may be diverse, but there is strong reason for deriving it from tyrosine, an important amino-acid, that is, one belonging to the series that build up proteins. When tyrosine is treated in air with a widely distributed ferment called tyrosinase, it becomes reddish and then black, and is practically indistinguishable from melanin. It is probable that melanins arise from tyrosine and related substances.

Another group of animal pigments includes the chromolipoids or lipochromes, the 'coloured fat-like bodies.' They are mostly reddish and yellowish pigments, such as occur in many brightly coloured birds and fishes, where melanins often accompany them. The colouring-matter of yellow fat in many animals has a chromolipoid nature, and reference has already been made to two chromolipoids, carotin and xanthophyll, that accompany chlorophyll. This is an important fact, for these two pigments occur also in many animals, e.g. carotin in butter and xanthophyll in the yolk of eggs, thus suggesting that chromolipoids in animals may be derived directly or indirectly from plants.

In higher crustaceans, such as rock-lobsters and prawns, a reddish chromolipoid (*zoonerythrin*), which is next door to carotin, is common. The blue colour of the common lobster is due to a compound of *zoonerythrin* with a protein. When the protein is destroyed by heating, the free pigment is left to give its familiar red colour to the boiled lobster.

There are many other animal pigments that cannot be included in any of the groups referred to—such as the uric acid pigments of some butterflies, the purple secretion of the dog-welk *Purpura* and some other Gastropods (the animal counterpart of indigo), the red pigment of the cochineal insect (a distant counterpart of the alizarin of madder), but it is perhaps more important to emphasise the great classes: the blood pigments, the melanins, the chromolipoids, and the chlorophylls—the last being almost confined to plants.

Physiology of Pigments.—Little can be said with any security as to the connection between the molecular structure of a substance and the colour to which it gives rise; and our knowledge of the physiological production of pigments is also very tentative. There are glimpses of light, however, in the derivation of melanins from amino-acids and the like, since these are constituents of the proteins which are present in all living matter. Similarly it is satisfactory when an animal lipochrome can be linked back to the

carotin or xanthophyll of plants. The 'flavone' or 'flavonol' of the wings of the marbled-white butterfly (*Melanargia galatca*) is probably derived by the caterpillar from the Cocksfoot or the Timothy grasses on which it feeds. Some pigments may be unhesitatingly classified as waste-products, such as the uric acid pigments of some butterflies. The carmine that sometimes forms half of the weight of a female cochineal insect (*Coccus cacti*) is a glucoside, yielding sugar when treated with dilute acid, and may perhaps be interpreted as a reserve product. Of others, it may be said vaguely that they are by-products of the everyday chemical routine (or metabolism) of the body. Another physiological problem is to correlate the pigmentation with external conditions. Thus in some cases the amount of pigment formed is known to vary with the temperature and the illumination. Albinism, i.e. the abnormal absence of superficial pigment, is probably due to a germinal perturbation, involving the loss of some essential pigment-producing factor, but the wan whiteness of the cave newt called *Proteus* is due to the absence of the light stimulus, as is experimentally proved by rearing the animal in a well-lighted laboratory. Melanism or darkening is probably in many cases a modification, hammered on from without by some environmental peculiarity; but there is also evidence that it may arise as a germinal variation.

Internal Uses of Pigments.—Apart from the problem of determining origin is the easier problem of discovering utility. Thus the blood-pigments are of value in capturing and transporting gases; cytochrome is probably of value in controlling the disposal of oxygen within the cell; eye-pigments, like retinal purple, may be auxiliary to vision; a superficial melanin may be protective against too intense illumination; and chlorophyll is important in connection with the absorption of orange-red rays of light.

External Utility of Colouring.—In many different ways the colouring of animals is of importance to their well-being in the struggle for existence. Thus, the green insects and reptiles which live in the grass or on trees, the sandy-coloured animals which are hardly to be detected against a background of similar colour, the white animals which are almost invisible among the snow illustrate protective colouring. This colour-resemblance between animals and their surroundings is sometimes marvellously exact, and doubtless of great advantage. Moreover not a few animals, among crustaceans, fishes, amphibians, and reptiles, have the power of changing their colour, for the pigment-cell or the pigmented protoplasm expands or contracts under stimulus, and this is in some cases a cloak of invisibility. The conspicuous colours of some unpalatable or noxious animals may be of everyday value in warning off possible molesters. It may also be that colours are sometimes useful in assisting mutual recognition between individuals, or in indicating attitudes and movements. The bright colour of the inside of the mouth of some nestlings may help the parents to transfer the food without fumbling. Sometimes the strong colour of a gaping mouth, as in a chameleon, may have some use in repelling intruders. Finally, in many animals the sexes differ markedly in colour, the males being almost always brighter than their mates. According to some, this depends on the constitutional peculiarities of maleness and femaleness, while Darwin has emphasised that the brightness of males has been enhanced by the selective taste of the females, and Wallace has urged that natural selection has retarded female butterflies and birds from attaining a brightness which would expose

them during the weakness or preoccupation of the reproductive period to the hungry eyes of their enemies. But our recognition of the way in which variations of colouring are fostered or eliminated in the course of natural selection must not lead us to forget the primary problems of the origin of the pigments, and of the physiological conditions which determine their distribution.

Pika. See OCHOTONA.

Pike (*Esox lucius*), a well-known fresh-water fish abundant in the temperate parts of Europe, Asia, and America. The body is long and covered with small cycloid scales; the dorsal fin is near the tail; the mouth is large, with strong, sharp teeth; the lips have no barbels; the stomach is without the usual pyloric appendages; the open (physostomous) air-bladder is simple; the gill-aperture is very wide. The fish is olive gray above, silvery white on the belly, and is mottled with pale spots; in length it may measure from 2 to 4 feet; and it may attain a weight of 10 to 20 lb., or in rare

Pike (*Esox lucius*).

cases, it is said, about 60. The genus includes besides four or five other species, notably the *Maskallonge* of the North American lakes, a 'grand game fish,' often 6 feet long, in habit a dauntless marauder. Another of smaller size (*Esox reticulatus*) is the common *Pickeral* of the eastern states. All three are valuable food-fishes.

The common pike or *Jack* (Scotch *Gadd*) is said to spawn when three years old. The ova are usually laid in March, but the spawning is protracted. There is great mortality among the young, which take about a week to hatch. Growth is at first rapid, and continues more slowly for years. The longevity of the fish is great, but the records of pike which have attained to 250 years are as unsatisfactory as the evidence for longevity usually is. There is no doubt, however, that they may outlive their keepers; and it is also true that they sometimes venture ashore, and that they sometimes lie in a torpid slumber in the pools. But the most characteristic quality of pikes is voracity. Feeding for the most part on frogs and small fishes, they are often prompted by hunger to bid for higher game, such as ducks, geese, water-hens, and water-rats. Thoreau describes the pike as the 'swiftest, coarsest, and most ravenous of fishes, which Josselyn calls the river-wolf. It is a solemn, stately, ruminant fish, lurking under the shadow

of a lily-pad at noon, with still, circumspect, voracious eyes; motionless as a jewel set in water, or moving slowly along to take up its position; darting from time to time at such unlucky fish or frog or insect as comes within its range, and swallowing it at a gulp. Sometimes a striped snake, banded for greener meadows across the stream, ends its undulatory progress in the same receptacle. The Bony Pike (*Lepidosteus*) is a Ganoid, and the name is sometimes applied to the marine Gar-fish (*Belone*) and to some American perches. See BONY PIKE, GAR-PIKE.

See the articles ANGLING and PISCICULTURE; Pennell's *Book of the Pike* (3d ed. 1884); and Bickerdyke's *Angling for Pike* (1888).

Pike, a word loosely used for almost any kind of lance or Spear (q.v.), whether larger or smaller headed, as used by infantry troops, and now superseded by the bayonet. The naval boarding-pike is a lance about the length of a man. The short pike, called *half-pike* or *sponton*, long carried by some classes of infantry officers in most European armies, was a kind of Halbert (q.v.) with a smaller but ornamented head, and was rather an emblem of dignity than a fighting weapon. In 1804, when a French invasion was threatened, pikes were distributed by government through the country; and the secret manufacture of iron pike-heads was one of the most disquieting features of the Radical reform agitation in 1819 and during the Chartist troubles.

Pike's Peak, a peak of the Rocky Mountains, in Colorado, 65 miles S. of Denver, discovered by Captain Pike, in 1806. It rises to a height of 14,134 feet. On its summit is one of the highest meteorological stations in the world; while at the base, at Colorado Springs, there is a low-level station. There is a railway to the top, 9 miles long ($4\frac{1}{2}$ miles of curves), with a maximum gradient of 1 in 4.

Pilaster, in Classical Architecture, a square pillar, sometimes standing free, but usually attached to a wall, from which it projects $\frac{1}{4}$ th, $\frac{1}{3}$ th, or other definite proportion of its breadth. Greek pilasters, or antæ, were of the same breadth from top to bottom, and had different capitals and bases from those of the orders with which they were associated. The Romans gave them a taper like the columns, and the same capitals and bases.

Pilaster.

Pilate, PONTIUS, the fifth Roman procurator of Judea and Samaria, from 26 to 36 A.D. He was personally convinced of the innocence of Jesus, and tried to save him, yet sent him to be crucified to appease the raving mob of Jerusalem, washing his hands before the people to show that he took no responsibility for his death. His rapacity and cruelties caused many outbreaks, which were sternly suppressed, and at length culminated in the murder of a number of Samaritans on Mount Gerizim, which caused such loud complaints that Vitellius sent him to Rome to answer to Caesar (36 A.D.). Eusebius tells us that Pilate made away with himself; others say that he was banished to Vienna Allobrogum (*Vienne*), or beheaded under Nero. In the Eastern Church there is a persistent tradition that he eventually embraced Christianity like his wife, and indeed in the Ethiopian Church Pilate is commemorated as a saint, his day falling on June 25. Pilate is said by Justin Martyr, Tertullian, and Eusebius to have forwarded to Tiberius for his own justification an account of the judgment of Jesus, but the so-called

Report, and *Acts of Pilate*, as well as the two letters of Pilate to Tiberius, have no claim to authenticity.

Many legends have clustered round the sinist figure of Pontius Pilate. One relates how his box was flung into the Tiber, and caused the river to overflow, and how it was next thrown into the Rhone near Vienna, but (according to the late form of the mediæval legend) again caused so great a storm that it was carried to Mount Pilatus near Lucerne, and there sunk securely in the deep pool on its top. But here again it made storms arise and every year to this day on Good Friday the devil lifts him out of the pool and sets him on judgment-seat, where he washes his hands anew. Pilate's wife, traditionally called Procla or Claud Procula, from her solemn warning to her husband against putting Jesus to death, has been regarded as a Christian by Origen, Chrysostom, and Hilary. In the Greek Church she is a saint, her day falling on October 27.

Pilatus, MOUNT (Lat. *Mons Pilatus*, 'the hooded peak,' from its top being frequently enveloped in cloud; the legends connecting Pilate with the place have presumably grown out of the altered name), an isolated mountain at the western end of the Lake of Lucerne, rising opposite the Rigi. The lower half is clothed with wood and meadow, where in summer many head of cattle are pastured; the upper portion is a mass of bare and jagged peaks, rising in the Tomlishorn to 6998 feet. Below the summit lies Lake Pilatus (see preceding article). On two of the peaks there are hotels; and since 1889 there has been a trolley and-rack railway from Alpnach to the top, when there is a splendid view of the Bernese Alps.

Pilau, or PILLAU, a dish common in Turkey, Egypt, Syria, and India, consists generally of rice thoroughly boiled, drained, and gently stirred with butter, pepper, and finely-chopped onions. For the tables of the wealthy, fowls, lamb, mutton, slices of ham or bacon, variously cooked, but always much boiled or roasted, are placed on the top of the rice, and served up with it.

Pilchard (*Clupea pilchardus*, or *Mosa sadina*), an important fish of the family Clupeidæ. The pilchard is nearly equal in size to the herring, but rather thicker, and the lines of the back are fewer; and the dorsal fin is rather further forward. The mouth is small, and in the adult fish destitute of teeth; the under-jaw is longer than the upper. The upper part of the body is bluish green, the sides and belly silvery white, the cheeks and gill-covers tinged with golden yellow, and marked with radiating striae, the dorsal fin and tail dusky. The pilchard is an inhabitant of more southern seas than

Pilchard (*Clupea pilchardus*).

the herring. In British seas it is abundant off the coasts of Devon and Cornwall, and the south and south-west coasts of Ireland; towards the east end of the English Channel it becomes scarce, and on the more northern coasts of the British Isles it is only taken occasionally in small numbers. It extends in abundance throughout the Bay of Biscay along the west coast of Portugal, and the shores of the Mediterranean; its southern limit is Madeira

In France this fish is known as *la sardine*. It is true that the sardines in oil imported into Great Britain are smaller than the majority of English pilchards, but they are of the same species. The English pilchard is usually about 10 inches long. The French sardine is said by Moreau to be from 12 to 20 cm. in length—i.e. 5 to 8 inches—sometimes reaching 25 cm. or 10 inches. The fish used for preserving in France are certainly young and not full grown. Pilchards are now prepared in oil in the same way as French sardines, at Mevagissey in Cornwall, and have an extensive sale; so are Sprats (q.v.) at Deal.

Unlike herrings, the pilchards which are captured are not in breeding condition, but are fat, with small reproductive organs. In fact the habits of the pilchard are the direct converse of those of the herring. The pilchard is found feeding near shore in more or less abundance for nine months of the year, but in June, July, and August, when as a rule none are being caught near shore, spawning pilchards are found at some distance, 10 to 50 miles or more, from the land. At this season a few are occasionally taken in mackerel nets, in which the largest ones are meshed in consequence of their swollen condition. The ova, unlike those of the herring, are quite transparent, and buoyant like those of the cod and mackerel; they pass through their development while suspended separately in the sea-water. Like the herring, the pilchard feeds upon minute crustacea and other animals, some adult, some larval, which swarm in the sea.

In Scotland the pilchard is known as the *Gypsy Herring*, *Garvie Herring* (the sprat being *Garvie*), or *Crue Herring*. See FISHERIES.

Pilcomayo, a river of South America, which takes its rise in two branches in the Bolivian Andes, in the department of Potosí, flows in a very winding course south-east through the Gran Chaco, separating Paraguay and Argentina, and finally joins the Río Paraguay a little below Asunción. The volume of water brought down is comparatively insignificant, much being spent in lagoons on its way; at the mouth there is scarcely any perceptible current, and the breadth is not 60 yards, while within the first 200 miles it narrows more than once to less than 20 yards, and moreover divides into branches, among some of which explorers, like Captain Page, have lost their way. There have been many attempts, all fruitless, made to open the river route between Argentina and Bolivia; since 1556 numerous expeditions have been sent out, and many of the explorers have perished. There are numerous rapids, and long canals would be required. In its upper course its sands are auriferous and the banks fertile; lower down the valley is swampy. The river's water is rendered like brine by the great salt lakes of the Chaco—in which part the river is hurried for hundreds of leagues in a great forest of fan-palms.

Piles are usually squared logs of wood used in engineering operations, such as dams, bridges, and roads (see COFFERDAM, &c.). They are sharpened, and, if necessary, protected with iron points. Piles are also used for permanent works, when they are driven through loose soil till they reach a firm bottom, and thus form a foundation on which buildings, roads, &c. may be placed. Cast-iron is also used for piles, which are cast hollow. Common piles are driven in by machines called *pile-drivers*. In these a heavy weight (or monkey) is raised to a considerable height between two guides, and then let fall on the head of the pile. The application of steam to these drivers has made them very powerful engines—Nasmyth's steam-hammer being a well-known instance. See also LAKE-DWELLINGS.

Piles, or HÆMORRHOIDS, are small swellings

situated either within or on the verge of the anus. The first step in their development is the dilatation of one or more veins in this region. They consist of folds of skin or mucous membrane, with the subjacent tissues in an inflamed, infiltrated, or permanently thickened condition, and usually contain enlarged veins, though these sometimes become obliterated. There are several varieties of these tumours. Sometimes the pile is mainly composed of a little knot of varicose veins; in this case it is readily emptied by pressure of the fluid blood contained in it, which, however, returns when the pressure is removed. Sometimes the blood coagulates, either in a dilated vein, or, if this has given way, around it, forming a solid tumour surrounded by tissues thickened in consequence of inflammation; or the tumour may consist of a kind of erectile tissue formed by an abnormal condition of the vessels of the mucous membrane; this variety is especially liable to bleed. These tumours are divided into *bleeding* and *blind* piles, according as they are or are not accompanied with hæmorrhage; and into *internal* and *external* piles, according as they are within or without the sphincter muscle of the anus.

The following are the general symptoms of this affection. The patient, after having experienced for a varying time a feeling of heat, fullness, and dull pain about the lower part of the bowel, becomes conscious of a sensation as if there were a foreign body in the anus, and on examination after an evacuation discovers a small tumour, usually about the size of a grape, which either remains outside or is retracted, according as it originated without or within the sphincter. This tumour gradually increases, and others form around it, until a mass at length may result as large as a pigeon's egg, or larger. In its ordinary *indolent* state the tumour has little sensibility, and occasions comparatively little annoyance; but when it is *inflamed* (from strangulation by the sphincter muscle, or from any other cause) it is exquisitely tender to the touch, and is the seat of burning and stinging sensations, rendering the evacuation of the bowels (and sometimes of the bladder also) difficult and painful. In women an inflamed pile may cause pain in the back, irritation of the womb, with mucous discharge, and many other anomalous symptoms. In severe cases the patient can neither stand nor sit with comfort, and only finds relief in the horizontal position. In internal piles the most important symptom, sometimes the first to be noticed, is hæmorrhage, which may be so profuse or so often repeated as to cause serious anæmia.

Piles may be caused by any circumstances which cause congestion in the lower bowel, such as luxurious and sedentary habits of life, pregnancy, and such diseases of the liver as tend to check the return of blood from the veins of the rectum. Moreover, anything that causes irritation of the rectum, such as excessive use of purgatives, dysentery, inflammation of the prostate gland, &c., may cause piles. But of all causes constipation is probably the most frequent; it operates in producing them partly by the pressure of the accumulated and hardened feces upon the veins carrying the blood away from the rectum, and partly by the straining and irritation such feces occasion during their evacuation.

In the treatment of piles it is expedient to relieve the congested state of the lower bowel by one or two doses of sulphate of magnesia, and a course of vegetable diet, after which the continued use of mild laxatives should be resorted to. A teaspoonful of an electuary, consisting of an ounce of confectio of senna, half an ounce of cream of tartar, and half an ounce of sublimar, if taken in the middle of the day, usually acts gently about bedtime,

which is far the best time for the bowels of patients of this kind to act, as the parts irritated by the passage of the evacuation become quieted during the night. It is most important that the piles should be carefully pressed back after every movement of the bowels. Amongst the milder forms of local treatment must be mentioned (1) the injection of the rectum with cold water both before and after the motion; (2) washing the anus with yellow soap and water after each evacuation—this should never be omitted by anyone who suffers from piles; (3) the application of gall ointment, adrenalin ointment, or of other astringents; and (4) the injection of astringent lotions, as, for instance, of sulphate of iron, in the proportion of a grain to an ounce of water. When the piles are inflamed, a suppository of morphia and cocaine relieves the pain; which is also eased by plunging the buttocks into a sitz bath or basin of very hot water; the inflammation generally subsides under the influence of rest in the horizontal position, fomentations, poultices, and low diet. In severe and prolonged cases operative interference becomes necessary. For external piles removal with seissors is usually employed. In certain forms of internal piles the application of caustics, especially injection of a few drops of pure carbolic acid into the centre of the pile, sometimes causes clotting in and disappearance of the pile. Where their removal is required it may be effected either by ligature or by canterisation, or in severe cases by excision of a ring of mucous membrane containing the piles.

The treatment of the hemorrhage that frequently accompanies piles requires a few words. If the bleeding is moderate in quantity, and has continued for some time without inducing weakness or any other bad symptom, it is not expedient to interfere with it. When, however, it obviously requires checking, the effect of cold water injected into the rectum, as already recommended, should be tried, and, in case of its failing, astringent injections should be had recourse to. At the same time the patient should remain in the horizontal position. Surgical interference to check the bleeding is seldom, if ever, necessary.

Pileus (Lat. 'a hat'), the upper expanded portion of many Fungi (q.v.).

Pilewort. See *IRANUNCULUS*, *CELANDINE*.

Pilgrim (Ital. *pellegrino*, Lat. *peregrinus*, 'a visitor of foreign lands'). A pilgrim is one who visits, with religious intent, some place reputed to possess especial holiness. The early Christians, like the Jews and the pagan Gentiles, regarded certain places with special religious interest; above all, the Holy Land, and particularly the scenes of the Passion of Christ at Jerusalem. St Jerome refers the practice of visiting Jerusalem to the discovery of the Holy Cross by St Helena. He himself was a zealous pilgrim; and throughout the 4th, 5th, and 6th centuries pilgrims habitually undertook the long and perilous journey to the Holy Land from almost every part of the West. Other sacred places, too, were held to be fit objects of the same visits of religious veneration. The tombs of the apostles Peter and Paul, and of the martyrs in the catacombs at Rome, are so described by St Jerome. St Basil speaks in the same terms of the tomb of the Forty Martyrs; and the historian Theodoret tells of not only visiting such sanctuaries, but of hanging up therein, as offerings, gold and silver ornaments, and even models of hands, feet, eyes, &c., in commemoration of the cures of diseases supernaturally obtained as the fruit of these pious visits. The Pilgrimage, however, pre-eminently so called, was that of the Holy Land; and, even after Jerusalem had been occupied by the Saracens, the liberty of pilgrimage, on payment of

a tax, was formally secured by treaty; and it was from the necessity of protecting pilgrims from outrage that the well-known Military Orders had their origin. The Crusades may be regarded as a pilgrimage on a great scale; the direct object being to secure for the Latin Christians immunity of pilgrimage. On the other hand, the final abandonment of the Crusades led to a great extension of what may be called domestic pilgrimage, and drew into religious notice and veneration many shrines in Europe, which, after the lapse of time, became celebrated places of pious resort. The chief places of pilgrimage in the West were, in Italy—Rome, Loretto (q.v.), Assisi; in Spain—Compostela, Guadalupe, Montserrat; in France—Fourvières at Lyons (q.v.), St Denis; in Germany—Maria Zell, Cologne, Trier; in Switzerland—Einsiedeln; in England—Walsingham, Canterbury; in Scotland—Whithorn, Whitekirk (near North Berwick), Loretto (Musselburgh), Scone, Dundee, Paisley, and Melrose; in Ireland—Station Island (see *PERC*), and many places connected with the life or death of the early Irish saints. The pilgrim commonly bound himself only by a temporary vow (differing in this from the palmer), which terminated with the actual visit to the place of pilgrimage, or at least with the return home, and by which he was bound for the time to chastity and to certain other ascetic observances. Many abuses arose out of these pilgrimages, the popular notions regarding which may be gathered—although, probably, with a dash of caricature—from Chaucer's *Canterbury Tales*, and from Erasmus's account of the pilgrimage to Walsingham (*Peregrinatio religiosus ergo*). Pilgrimages have gone much into disuse in France since the Revolution. In late years, however, pilgrims have resorted in large numbers, not only to the ancient sanctuaries of Fourvières, Puy, &c., but also to La Salette, Paray-le-Monial, and since 1858 to Lourdes. Knock (q.v.) became in 1880 a resort of Irish Catholics; Calfn, near Motherwell, in 1922 of Scottish. Pilgrimage is of cardinal importance to Hindus (see *BENARES*, *HARDWAR*, &c.) and to Moslems (see *HAJJ*, *MECCA*). Positivists also visit the places connected with the lives of selected great men. See Jusseind's *English Wayfaring Life in the Middle Ages* (1888, new ed. 1920), and Sidney Heath's *Pilgrim Life in the Middle Ages* (1912); and for the historic route from Winchester to Canterbury, see *The Old Road*, by Hilaire Belloc (1905) and *The Pilgrims' Way*, by Julia Cartwright (new ed. 1912).

Pilgrimage of Grace, a rising of the rural population in Lincolnshire and Yorkshire in 1536. When the commissioners charged with the suppression of the minor monasteries arrived in Lincolnshire, reports were spread abroad among the people that all the church jewels and plate were to be taken away, that most of the churches were to be pulled down, that new taxes were to be levied, and that the rights of the commons were in other ways to be vexatiously interfered with. The rising began at Louth on 1st October; 20,000 men soon gathered at Lincoln, under the leadership of Dr Mackerel, Abbot of Barlings, a shoemaker named Melton, better known as Captain Cobbler, and some of the dispossessed monks and gentry. But the approach of the Duke of Suffolk from the south, and a proclamation by the Earl of Shrewsbury, who was drawing near from the west, stating that what had been done was with the consent of parliament, and promising a free pardon to the rebels, caused them to disband and go away home (October 13). In the meantime a similar rising for precisely similar causes had taken place in Yorkshire; it began on 9th October in the East Riding, the chief leader in the movement being a lawyer named Robert Aske. The rebels, 40,000 in number, took York and Ponte-

fract, capturing in this last town Lord Darey and the Archbishop of York (not unwilling to be captured). The king sent against them the Earl of Shrewsbury and the Duke of Norfolk, and on the reading of a similar proclamation to that in Lincolnshire they dispersed to their homes. In the following year Aske, Sir Robert Constable (who had been associated with Aske in the leadership), Lord Hansey (suspected of complicity in the Lincolnshire movement), Mackerel, and others, about twenty in all, were executed. See Gairdner's preface to *Calendar of State Papers: Henry VIII.*, vol. xi. (1888), and a book by M. H. and R. Dodds (1915).

Pilgrim Fathers, generally known in American history as THE PILGRIMS, the founders of the first English colony to be permanently settled in New England. They belonged mostly to a set of separatists (Brownists) from the Church of England. Originating in Yorkshire they had established independent churches at Scrooby in Nottinghamshire and at Gainsborough in Lincolnshire at the end of the 16th and at the beginning of the 17th century, and, in 1608, seeking escape from religious persecution, had fled to Holland, first to Amsterdam and then (1609) to Leyden where they formed a church. With little hope of returning to England, and desirous of preserving their distinctive national character and of realising what they believed to be their providential calling of founding a new church and of spreading their religion in some remote part of the earth, they turned to the New World and sailed in the *Speedwell* from Delfshaven about 22nd July 1620; in the *Speedwell* and the *Mayflower* from Southampton (here they had been joined by associates in England), 5th August, and later from Dartmouth, where the *Speedwell* had put in for repair; and in the *Mayflower* from Plymouth (a depleted company, the *Speedwell* having there been abandoned), 6th September. The company (exclusive of the crew) sailing from Plymouth numbered in all 102 persons, men, women, and children, and was bound for the banks of the Hudson within the colony of Virginia; but after a long and stormy voyage they landed, 21st December (though in the United States Forefathers' Day marking the event is celebrated on the 22d), on the bleak shores of Cape Cod at a point to which Captain John Smith in the course of an exploration in 1614 had given the name of Plymouth. Here was founded the colony of Plymouth (q.v.), which existed as a separate state from 1620 till, under a charter of 1692, it was united to the colony of Massachusetts Bay, which after 1628 had been established by Puritan emigrants from England to be distinguished from the Pilgrim Fathers (see MASSACHUSETTS). Soon the earliest Plymouth colonists were joined by others from the church at Leyden, and by 1631 almost the whole of that body had emigrated. The first years of the colony were years of much difficulty and of great privation. From the outset democratic government was established, and communism at first was practised but gradually was forsaken, and in 1626 was completely abandoned. A religious illiberality which came to be displayed is to be viewed, it has been held, only in relation to the prime necessity of maintaining civil order. Though the Virginia Company founded the first permanent English colony in America the Pilgrim Fathers formed the nucleus of the New England states, and as such are peculiarly revered in the United States as pioneers and natural founders. In 1894 a General Society of Mayflower descendants was organised to preserve the memory, records, and history of the pilgrims and their stock. Among notable pilgrims were Myles Standish (q.v.) and William Bradford (1590-1657), historian of the

colony and its governor (except for five years' interval at his own request) from April 1621 till his death. See also ROBINSON (JOHN). A barn at Jordan's Hostel, Chalfont St Giles, Buckinghamshire, is held by Dr Rendel Harris (see his *The Finding of the Mayflower*, 1920) to have been built of the veritable timbers of the *Mayflower*.

See the Massachusetts Historical Society's edition (2 vols. 1912) of Bradford's *History of Plymouth Plantation, 1620-31*, written after 1630 and first printed in 1856 from the original MS., which, lost it is supposed during the War of Independence from the New England Library, in the tower of the Old South Church, Boston, reappeared in the Fulham Library, London, but was not generally identified till 1855, and was returned to the United States in 1898, being deposited in the Massachusetts archives. See also Goodwin, *The Pilgrim Republic* (1888); John Brown, *The Pilgrim Fathers of New England* (1895, new ed. 1920); H. M. & M. Dexter, *The England and Holland of the Pilgrims* (1905); and works by Devereux (1887), Arber (1897), Usher (1919).

Pilibhit, a town in the United Provinces of India, 30 miles N.E. of Bareilly; pop. 32 000

Pili-nuts. See CANARIUM.

Pillar, a detached support like a column; but its section may be of any shape, whereas the column is always round. Pillars have been used in all styles of architecture, and their forms and ornaments are usually amongst the most characteristic features of the style. The Greek and Roman pillars (or columns) are the distinguishing elements in the various orders. In Gothic architecture, also, the pillars or piers are of different forms at the various epochs of that style. In the Norman period we have plain massive pillars, square, circular, and octagonal, frequently ornamented with zigzag ornaments, spiral bands, &c. on the surface (fig. 1). As vaulting progressed, the system of breaking the plain surface of the pier, and giving

Fig. 1.
Norman Clustered Pillar.

to each portion of the vaulting a separate little column or shaft to support it, was introduced. This was done either by attaching shafts to the pillars or by cutting nooks in the pillars and setting little

shafts in them, as at *a*, *b*, fig. 2. In the Early Pointed style a plain circular or octagonal pillar, with a number of small shafts attached around it, is a favourite arrangement, as at *c*, *d*, fig. 2. In this style the attached shafts are very frequently banded to the main pillar at different heights, and they are sometimes made of a finer material, such as Purbeck marble. In the Decorated style the pillar is of a lozenge form, and not so much ornamented with detached shafts as with mouldings; plain, circular, or octagonal pillars, however, are used in this, as in all the styles. The mouldings and shafts are usually filleted; and some of the mouldings run up into the arch without any cap. In Perpendicular the same idea is further carried out; the mouldings become thinner, and are more frequently run up into the arch without caps. See FLAMBOYANT.

Pillar-saints, an English rendering of the Greek *stylitai*, the name of a class of hermit-ascetics, chiefly Syrian, who crucified the flesh by living on the summit of pillars in the open air. The most noted was Simeon called Stylites (q.v.).

Pillars of Hercules. See HERCULES, PILLARS OF.

Pillau, a Prussian town and fortress on a spit of land at the entrance of the Frisches Haff, 25 miles W. of Königsberg, of which it is the outer port—by a good channel; pop. 10,000.

Pillnitz was the ordinary summer residence of the royal family of Saxony, in a beautiful situation on the Elbe, 5 miles SE. of Dresden. The palace embraces three main buildings or 'castles,' and is surrounded with beautiful parks and gardens, particularly rich in conifers. It is now a school of gardening. Here, in August 1791, the Declaration of Pillnitz was framed, in which Austria and Prussia called upon the European powers to take common action on behalf of the royal family of France against the republicans, at the same time safeguarding the liberties of the French people.

Pillory, an engine for the public punishment of criminals, disused in Britain since 1837, but previous to that time commonly employed, as it also was in France and Germany. It consisted of a stout plank fixed like a signboard on the top of a pole, the pole being supported on a wooden platform elevated above the ground. Above, and parallel to this plank, another of like dimensions was placed in a similar position with respect to the pole, and fixed to the former by a hinge, being thus capable of being moved upwards from it, or closed upon it, when necessary. A large circular hole was cut, with its centre in the line of junction of the two planks, and two corresponding holes of smaller size were formed, one on each side of it; the large hole was for receiving the neck, and the two smaller the wrists. When a criminal was to be placed in the pillory he was made to mount and stand upon the platform; the upper of the two hinged planks was raised to allow the culprit's neck and wrists to be inserted in their proper grooves, and then brought down into its place, and fastened by a padlock, or in some other way. The pillory seems to have existed in England before the Conquest, in the form of the *stretch-neck* (an instrument by which the neck only was confined), and was originally intended, according to the 'Statute of the Pillory' (51 Hen. III. chap. 6), for persons guilty of forestalling and regrating, using deceitful weights and measures, perjury, &c. Its use was exclusively confined to this class of offenders till 1637, when restrictions were put upon the press, and all who printed books without a license were put in the pillory. From this time it became the favourite mode of punishing libellers

against the government, and many eminent men were accordingly from this time pilloried, among them Leighton, Lilburn and Warton the printers, Prynne, Dr Bastwick, and Daniel Defoe. These sufferers were popular favourites, and the encouragement, applause, and sympathy of the crowd around converted the intended punishment into a triumph; but such men as Titus Oates, and the class of offenders including perjurers, swindlers, polygamists, &c., who were objects of popular hatred and disgust, were pelted with rotten eggs, garbage, mud, sometimes even with more dangerous missiles. In 1797 the preacher Thomas Evans was pilloried for singing a seditious Welsh song; so too, in May 1812, was Eaton, the publisher of Paine's *Age of Reason*; and in 1814 the celebrated naval hero Lord Cochrane, afterwards Earl of Dundonald (q.v.), was sentenced to stand an hour in the pillory, but the government did not dare to carry the sentence into effect. The punishment was abolished for all offences save perjury in 1815; totally in 1837. The perjurer Peter James Bossy was the last to stand in the London pillory, in the Old Bailey, for one hour, on 22d June 1830. In France the pillory was anciently called *pilon* (a word of uncertain origin), and in recent times *carcan*, from the iron collar by which the criminal's neck was attached to the post; and even so late as 1840 a woman who had poisoned her husband was at least sentenced to the pillory at Tulle as part of her punishment.

Defoe's occupancy of the pillory on the 29th, 30th, and 31st July 1703 was memorable in many ways, and helped to deprive the pillory of its terrors. He ingeniously took the opportunity of publishing on the first day of his appearance there his vigorous *Hymn to the Pillory*; the crowd was on his side, and, instead of pelting him with unpleasantness, crowned the pillory with flowers and drank the martyr's health. 'Damnable on high stood unabashed Defoe,' like a new Simeon Stylites, and his temper was apparently infectious.

See DANCE, *Illustrations of Shakespeare*; Griffiths, *Chronicles of Newgate*; Andrews, *Punishments in the Olden Times*; and Jewitt in the *Reliquary* for April 1861. See also JOUGS, CAGE, STOCKS, and STOOL OF REPENTANCE.

Pills are the most generally convenient and popular of all forms of medicine. They are formed from masses of a consistence sufficient to preserve the globular shape, and yet not so hard as to be of too difficult solution in the stomach and intestines. This form is especially suitable for drugs which operate in small doses, as aloe, colocynth, &c., while the disagreeable taste is always less than when the drug is given in solution. It is also useful where it is desired that the drug shall not dissolve in the stomach or upper intestines, but shall act only in the lower intestines. In such cases the pills may be coated with keratin, which is only soluble in the lower bowels. Many substances, such as vegetable extracts, may be at once formed into pills without any addition; but most substances require the addition of a material termed an excipient for converting it into a pill-mass. The excipients in most common use are bread-crumbs, hard soap, extract of liquorice, mucilage, syrup, treacle, honey, castor-oil, and conserve of roses. From the property of preserving pills for a long time in a properly soft state the most valuable excipient is the conserve of red roses; and, perhaps, next to it treacle is the most valuable excipient, as it does not undergo any change by time, but maintains a proper consistence, and preserves the properties of vegetable powders unimpaired for years. It is common to place pills in some fine powder to prevent them from adhering to each other, and to conceal their taste. For this purpose liquorice powder, wheat-flour, starch, and

magnesia are generally used in Britain, and lycopodium on the Continent. Pills retain their moisture and activity far longer in small bottles than in the ordinary pasteboard boxes. The ordinary weight of a pill is five grains; if it much exceeds that weight it is too bulky to swallow conveniently if consisting of vegetable matter. It is very common to meet with patients who express their inability to take this form of medicine. If, however, they practise with a small glolular mass towards which they feel no repugnance, as a pellet of bread or a currant, placing it on the back of the tongue and gulping it down with water, they will soon get over the difficulty.

To many people the taste of pills is a great deterrent, and various methods of coating the pills are resorted to for their benefit. Formerly coating with gold or silver leaf and coating with a little tolu resin dissolved in chloroform were the only methods; but more recently gelatine-coated, sugar-coated, and pearl-coated pills have been prepared in vast quantities and have become very popular. There is, however, a risk of deterioration owing to the length of time which they may be kept before being sold. See also QUACK DOCTORS.

Pillwort. See WATER-FERNS.

Pilocarpine. See JABORANDI.

Pilot is a person specially deputed to take charge of a ship while passing through a particular sea, reach, or dangerous channel, or from or into a port. Pilots are of three classes—(1) those licensed to act in districts where the pilotage is compulsory; (2) those licensed to act where the pilotage is not compulsory; (3) unlicensed pilots. British pilots are licensed by the Trinity Houses of London, Hull, Newcastle-on-Tyne, and Leith, and by Pilotage Commissioners in other ports. The British law relating to pilotage has been consolidated by the Pilotage Act 1913, which repeals Part X. of the Merchant Shipping Act 1894, and certain of the other sections in the Merchant Shipping Act. The Pilotage Act substitutes for the prior legislation, which was frequently confused and inconsistent: (1) a general Pilotage Act extending to the United Kingdom and the Isle of Man, and applicable to all ships, British and foreign; (2) a Pilotage Order applicable to the particular district; (3) bye-laws of the local pilotage authority. By this Pilotage Act, a licensed pilot is always entitled to supersede an unqualified pilot, and in such a case the master must pay to the unlicensed pilot a proportionate sum for his services, and may deduct the sum so paid from the sum payable to the licensed pilot. The scale of pilotage fees paid by the ship depends upon the distance piloted and the ship's draught of water. The fees earned are sometimes retained by the pilot earning them, less deductions for collection, superannuation, sick, or widows' funds, and sometimes they are thrown into a joint stock.

A British pilot-boat must have conspicuously painted upon it its number, owner's name, and the port to which it belongs, and must show a large flag of two horizontal stripes, the upper white and the lower red. At night a pilot-vessel on its station shows a white light, and in addition shows a flare at intervals not exceeding fifteen minutes. Ship-masters or mates are often licensed to act as pilots for their own vessels.

At common law the pilot, being appointed by the owners, or their servant the master, is their agent, and they are responsible for damage done by the ship while under his charge. By the Pilotage Act 1913, the liability of the owner or master of the ship for damage caused by her, or by any fault in her navigation is made the same in a district where pilotage is compulsory as in a district where

pilotage is not compulsory; in other words the fact of the ship being under compulsory pilotage will not relieve the owner or master of any liability for loss or damage occasioned by her wrongful navigation.

Pilot-fish (*Naucrates ductor*), a well-known fish which accompanies sharks and follows ships. It usually keeps to the open sea, and is very widely distributed in tropical and temperate regions. From the Mediterranean it sometimes follows ships to

Pilot-fish (*Naucrates ductor*).

British coasts. In length it is about a foot, in shape like a mackerel, in colour variable, though generally grayish blue with five transverse dark blue bands. The first dorsal fin is represented by a few spines. Its zoological position is beside the horse-mackerels in the family Carangidae.

Many wonderful stories are told about the pilot-fish, which seems to be the *Pomplius* of the ancients. It is said to guide the shark to its prey—nay, more, to show sailors their desired course. It certainly is a very frequent companion of the shark, especially if that fish be swimming alone, but the precise nature of the association is doubtful. The pilot-fish probably follows the shark as it follows a ship for the sake of scraps of food, and perhaps eats the parasitic crustaceans, &c., with which the skin of the shark is often infested. Moreover, companionship with the shark probably protects the pilot-fish from its enemies.

Piloty, KARL VON, German painter, was born at Munich 1st October 1826, studied at its academy under Schnorr and Schorn, and abroad under the French and Belgian masters of colour. In 1856 he was appointed professor of painting at the Munich Academy, and in 1874 succeeded Kaulbach as director. He died at Munich 21st July 1886. Piloty inaugurated a new era in the school of Munich, and his great work was through it to restore the colour element to German art. All his best pictures belong to the class of historical genre, and through him the centre of German historical painting came to be Munich. Several of his historical paintings adorn the sumptuous palaces of art built by the Bavarian kings at their capital, as the Maximilianen and the New Pinakothek. Piloty was a pronounced realist, but he tended to distort the relative importance of essentials and subordinate details, and, in spite of his skill as a portraitist, his pictures frequently have a theatrical air. His drawing was strictly objective; but he allowed his personal tastes all the more freedom in the choice of subject and in the employment of colour. Most of his pictures have melancholy subjects; amongst the best of them are 'Sani beside the Body of Wallenstein,' 'Nero amid the Ruins of Rome,' 'Wallenstein's March upon Eger,' 'Galilee in Prison,' 'Columbus,' 'Death of Caesar,' 'Announcement of the Sentence of Death to Mary Stuart,' 'Thurselda in the Triumph of Genucius,' and 'Death of Alexander the Great.' Piloty was a famous teacher, and among his pupils were Makart, Defregger, Lenbach, Max, Dietz, and others. See Stieler, *Die Pilotschule* (1881), and Rosenberg, *Die Munchener Malerschule* (1887).

Pilpay. See BIDPAY.

Pilsen (Czech, *Plzeň*), the second town of Bohemia, situated in a fertile and beautiful valley, 67 miles by rail SW. of Prague. There are numerous active industries, producing sulphuric acid, building materials, machinery, metal-work, porcelain, spirits, liqueurs, leather, &c. In the neighbourhood are mines of iron, alum, vitriol, and coal. The great Skoda armament and ordnance works, devoted after the Great War (other works in Czechoslovakia being incorporated) mainly to steel manufacture and to engineering, were established here in 1869. But the town is most widely known from giving its name to the most approved kind of Bohemian beer. The town was stormed by Ziska in the Hussite war and by Count Mansfeld in the Thirty Years' War (1618); it was Wallenstein's headquarters in 1633-34. Pop. 88,000.

Pilsudski, **JÓZEF**, Polish soldier and statesman, was born of Lithuanian-Polish noble stock at Żulów in the then Russian government of Vilno, 19th March 1867. Even while at school at Vilno he was a member of a circle of Polish revolutionaries, and later, when a student of medicine at Kharkov, was expelled for his socialist and nationalist activities. In 1887 at St Petersburg, although innocent, he was summarily despatched for five years to Siberia for alleged complicity in a plot against the Tsar. In 1892 he returned to Russian Poland and became one of the chief founders of the Polish Socialist Party, whose primary object, united to the general aims of labour, was the emancipation of Russian Poland from tsarist rule. He founded also, in 1894, the at first secretly issued journal *Robotnik* ('The Workman') of the party; his connection therewith, however, having at the last been discovered, he was imprisoned in 1901; but later, successfully simulating madness, made good his escape to Sweden, and in 1902 returned to Russian Poland. It was a conviction of Pilsudski's that independence for Poland was to be won from Russia only by force and not by peaceful means, and by organising a military element in the Polish Socialist Party he sought to create a secret national army; but the activities of the force ran to little more than banditism. In 1907, in consequence of the suppression of the revolution of 1905, Pilsudski was obliged to seek refuge in Austrian Poland, and by making use of athletic clubs (*sokols*) and rifle clubs he continued the work of organising a national army, to be turned against Russia when occasion presented. The Great War furnished the moment, and, assembling his Polish legion, Pilsudski crossed into Russian Poland and seized Kielce. Thereafter, however, the force fell into the hands of Austro-Polish politicians, against Pilsudski's will was made subject to the Austrian command, and was freely exploited in the interests of the Central Powers. It was then that Pilsudski, with a view to creating a real national army to be used solely in the cause of an independent Poland, established his secret Polish military organisation. He remained, however, with the legion, but shortly was removed from his command for insubordination, and later, having refused to raise a Polish army for the assistance of the Central Powers, was imprisoned at Magdeburg. But on the outbreak in 1918 of revolution in Germany he was released, and returning on 14th November—Polish independence had been proclaimed on the 9th—was received with acclamation, invested with dictatorial powers, and became provisional president. Thereafter, on the basis of the work of the military organisation, a Polish army was established, and by it, and by display of non-party statesmanship, Pilsudski raised the new Poland from the dangers external and internal

which threatened it. Of the three wars (with the Ukrainians, with the Czechoslovaks, and with the Bolsheviks), in which in 1919-20 Pilsudski led the Polish army, the third had European bearings in so far as it checked the westward advance of Bolshevism. The election according to the constitution of the president in December 1922 brought the end of political office, and shortly thereafter, having also retired from the leadership of the army, Pilsudski withdrew into private life. In 1926, however, he effected, with some bloodshed in Warsaw, a successful military revolt, and, having ejected the existing government, was subsequently elected president, but refused acceptance of the office, though by retaining the post of minister of war, which after the first success of his rising he had assumed, he remained in control of the army.

Piltown. See EOANTHROPUS.**Pilularia.** See WATER-FEINS.

Pimento, also called **ALLSPICE** or **JAMAICA PEPPER**, the dried fruit of *Pimenta officinalis*, a small myrtaceous tree which grows to the height of 20 or 30 feet, and has oblong or oval leaves about 4 inches long, of a deep shining green, and numerous axillary and terminal trichotomous panicles of white flowers, followed by small dark purple berries. The pimento tree is cultivated in some of the West Indian Islands. It is a very beautiful tree, with straight white trunk and much-branched head; about the month of April it is covered with an exuberance of flowers, which diffuse a rich aromatic odour. The leaves and bark partake of the aromatic property for which the fruit is valued. The fruit, when ripe, is filled with a sweet pulp, and the aromatic property has then in a great measure disappeared. The gathering of the berries, therefore, takes place as soon as they have reached their full size, which is about that of peppercorns. Their colour changes in drying from green to reddish-brown. The name *Allspice* was given from a supposed resemblance in flavour to a mixture of cinnamon, nutmeg, and cloves. Pimento is much employed in cookery, and is also used in medicine as a carminative and stimulant to prevent the griping of purgatives, and to disguise the taste of nauseous drugs. It depends for its properties chiefly on a volatile oil, *Oil of Pimento*, which is obtained by distillation with water. The leaves are used for tanning. From the oil extracted from the young shoots vanillin can be made.

Pimlico, a district of London between Westminster and Chelsea, strictly includes the fashionable Belgrave; but the name is now usually reserved for the less distinguished southern riverside portion. Within the confines are Buckingham Palace and the railway terminus of Victoria. The district was formerly one of public gardens much frequented in holidays. It takes its name from Ben Pimlico, famous in the later 16th century and after for his nut-brown ale.

Pimpernel (*Anagallis*), a genus of Primulaceae, having a wheel-shaped corolla, and the capsule opening by division round the middle. The species are elegant little annual and perennial plants, natives chiefly of temperate climates. The flowers are not large, but very beautiful. The Scarlet Pimpernel (*A. arvensis*) is a common plant in Britain, occurring as a weed in fields and gardens; it is common also in most parts of Europe and in many parts of Asia. The flowers are of a fine scarlet colour, with a purple circle at the eye. The flowers close very readily on the approach of rain; hence the name Poor Man's Weather-glass. They usually open about eight in the morning, and close about noon. The Blue Pimpernel (*A. carulea*) is far less common in

Britain, but very abundant in some parts of Europe. The Bog Pimpernel (*A. tenella*), frequent in bogs in England, but rare in Scotland, is an exquisitely beautiful plant. Several species are cultivated in flower-gardens. Acrid properties prevail in this genus. The name Water Pimpernel is given to *Samolus Valerandi*, also called *Brookweed*, another British plant of the same family, with racemes of small white flowers, growing in watery gravelly places. It is supposed to be the *Samolus* which Pliny says the Druids gathered fasting, with the left hand, and without looking at it, ascribing to it magical virtues in the cure and prevention of diseases in cattle. It is distributed over almost all the world. See also *LYSIMACHIA*.

Pimples. See PAPULES, ACNE, PUSTULE.

Pin. See PINS.

Pina Cloth, a beautiful fabric made of the fibres of the leaves of the pine apple plant. See *FIBROUS SUBSTANCES*, *BROMELIACEÆ*.

Pinar del Río, capital of the Pinar del Río province (area, 5206 sq. m.; pop. 274,000), Cuba, some 100 miles WSW. of Havana, with which it is connected by road and rail. It is the centre of the famous Vuelta Abajo tobacco-growing district. Pop. 50,000.

Pinchbeck, a reddish-yellow alloy of 4 parts of copper to 1 of zinc; much employed at the beginning of the 19th century in making watch-cases and other small articles in imitation of gold. It was named after its inventor, Christopher Pinchbeck (c. 1670-1732), a London clockmaker.

Pinckney, CHARLES COTESWORTH, American statesman, born at Charleston, South Carolina, 25th February 1746, was educated at Westminster and at Christ Church, Oxford, read law at the Middle Temple, and studied for a while at the military academy in Caen. He afterwards settled as a barrister at Charleston. He was Washington's aide-de-camp at the battles of Brandywine and Germantown, and afterwards, as colonel, saw much active service, until 1780, when he was taken prisoner at the surrender of Charleston. A member of the convention that framed the constitution of the United States (1787), he introduced the clause forbidding religious tests as a qualification for office. In 1796 he was sent as minister to France, but the Directory refused to receive him, and he had to quit the country. And in 1797, along with John Marshall (q.v.) and Ellbridge Gerry, he had little better success; it was while on this mission, which produced the XYZ correspondence (q.v.), that, when it was intimated that peace might be granted in return for a money payment, Pinckney is said to have made the reply, 'Millions for defence, but not a cent for tribute.' In 1804-8 he was twice an unsuccessful Federalist candidate for the presidency. He died 16th August 1825.

Pindar (Gr. *Pindaros*), the chief lyric poet of Greece, was born about 522 B.C. of Theban family at Cynoscephalæ, near Thebes, the capital of Boeotia, a district in which music and poetry were widely cultivated. His family, the Ægeidæ, was an old and illustrious one, often mentioned in the heroic legends. His father or his uncle was a flute-player, and Pindar inherited the musical talent of his family. He made music and poetry his profession, and was placed under the tuition of Lasus, a well-known musician and poet, at Athens. Though Thebes was the bitter foe of that city, Pindar often speaks of Athens with love and veneration. But Pindar seems, as a poet, to have been influenced far more deeply by Corinna and Myrtis, two poetesses then famous, with whom he

the young poet with her advice, judiciously as it would seem. It is said that she urged him to introduce mythical subjects into his poems, and then, when he had composed an ode introducing almost the whole Theban mythology in the first six verses, she smiled and said: 'We ought to sow with the hand, and not with the whole sack.' He commenced his career as a composer of choral odes for special occasions at the early age of twenty with a song of victory which still remains (*Pyth. X.*, composed in 502). He soon reached the highest rank in his profession, and composed odes for persons in all parts of the Greek world. He was employed by the Sicilian rulers, Hiero of Syracuse and Thero of Agrigentinum, by Arcesilaus of Cyrene and Amyntas of Macedon, as well as by the free cities of Greece. Wherever he went, he was honoured and loved for his own sake as well as for his art. States vied with one another in doing him honour; great cities like Athens created him their public guest. Though a frequenter of princely houses and king's palaces, he never lost his independence. In his poems he gives advice and reproof as well as praise to his patrons. He warns the great Hiero to avoid flatterers, and cautions Arcesilaus of Cyrene against undue severity. He resided four years at the court of Hiero. He died about the age of eighty in 443 B.C. Two conquerors—Pausanias, king of Sparta during the Peloponnesian war, and later Alexander the Great, who left no other dwelling in Thebes standing—spared the house of Pindar.

Pindar was in the prime of life when Salamis and Thermopylæ were fought, when Greek energy and enterprise were at their highest, and Greek poetry and philosophy were opening into their richest blossom. But his poetry belongs to the old rather than the new period of literature. In spite of his admiration for Athens, which he calls 'the pillar of Greece,' the spirit of Athens did not lay hold of him. Intellectually, he stands nearer to the age of Homer than to that of his contemporary Æschylus. Pindar's language is

of maidens (*parthênai*), convivial songs (*skoloi*), dirges (*thrênai*), and odes in praise of princes (*enkômiai*). Of all these poems we possess fragments only, often very beautiful, but his *Epimikra* or Triumphant Odes have come down to us entire. They are divided into four books, celebrating the victories won respectively in the Olympian, Pythian, Nemean, and Isthmian games. The special occasion for which these odes were composed explains their character. A victory won either in the chariot-race, for prowess in wrestling or other exercises, or for skill in music was held to confer honour not only on the winner and his family, but also on his city, and received a solemn celebration, partly religious, partly convivial and joyous. For the occasion an ode was composed, and was sung by a chorus. Pindar treats the victory not as a mere incident, but as connected with the victor's whole life and history. He loves to dwell on the moral side of it, not merely on the bodily prowess which gained it, but on the virtues which secured the favour of the gods who granted success. The plan of his poetry is intricate, and the connection of the different parts is often very hard to see. Pindar takes up various trains of thought, either relating to the victor, his ancestors, the history of his city, or else moral reflection; he breaks off each of these before the application is seen, and it is not till

the end of the poem that he weaves the different threads together and explains the allusions. Thus, says Müller, 'the curiosity of the reader is kept on the stretch throughout the entire ode.' The great merit of Pindar's poetry is its vividness and picturesque power, seen even in single epithets, as when he calls the mountain-mass of Etna, overtopping all heights in the island, 'the forehead of fertile Sicily.' It is this vigour and vividness which suggest Mrs Browning's picture of 'bold, electric Pindar . . . with race-dust on his cheeks,' and eyes that seem to see 'the chariot rounding its last goal.' The description of the happy lot of the god after the final judgment in the Islands of the Blessed (*Ol. ii.*), the voyage of the Argonauts (*Pgth. iv.*), and the vivid picture of the eruption of Etna in the First Pythian illustrate this power. To us his poems are specially interesting because they show as in a mirror the intense admiration of the Greeks for bodily prowess, strength, endurance, and beauty. Such gifts came in him a feeling of religious veneration; they come from the gods and are sacred. The ground-work of Pindar's poems consists in those legends which form the Greek religious literature. It will be seen that his life was intimately associated with the observances of Greek religion. In connection with the worship at Delphi he received unique honours. The belief in his devoutness as a worshipper of the gods shows itself in the legend, which apparently sprang up during his life, that the god Pan was seen and heard in a glade between Citharon and Helicon singing one of Pindar's hymns. When once asked what sacrifice he intended to offer at Delphi, he answered 'a psalm,' a reply not presumptuous, for his odes are full of religious feeling, not formal but real. His protest against myths dishonouring to the gods shows a truly reverent nature and an enlightened belief. Both in its strength and in its deficiencies his poetry reminds us of his claim on his own behalf: 'That man is wise *who knows much by natural genius*;' but the poets, his rivals, 'those *who have learned*, the versatile talkers, are but as zeus vainly clattering against the divine bird of Crows.' Thus the distinction between genius and talent is as old as Pindar's time. This high faith in his own poetic inspiration must not be mistaken for self-confidence; but it almost verges on a contempt for art which seems responsible for the frequent intricacy and obscurity of his poetry.

See editions by Boeckh (1811-21); Dissen (1830); re-edited by Schneidewin, 1840-47—commentary excellent but incomplete; Tychon Monmsen (1864); Fennell (1879-83; new ed. 1893-99); Bury (*Nemean Odes*, 1890; *Isthmian Odes*, 1892); O. Schroder (1908); Sir John Sandys (with Eng. prose trans. 'Loeb Classical Library,' 1915); English translations, in prose, by Paley (1869); E. Myers (2d ed. 1883); in verse by Carey (1833) Way (1922). The chapter in Müller and Donaldson's *History of Greek Literature* is full of sound criticism; and see works by Morice (1879) in English, by Villemain (1859) and Crouzet (1880); 3d ed. 1896) in French, and by L. Schmidt (1862), Friedländer (1863), and Lübbert (1882) in German. Fragments of some of the psalms, hitherto unknown, were found at Oxyrhynchus in Egypt in 1905-7.

Pindar, PETER. See WOLCOT.

Pindarics are in a general sense odes written in imitation of the Greek odes of Pindar, but by special English literary usage are rather odes of this kind where the imitation is merely fancied. In form the odes of Pindar are essentially strict and ordered, but the pindarics of English literature, based on a misunderstanding of the nature of Pindar's prosody, are characteristically loose and irregular. The form enjoyed great vogue in the late 17th and early 18th century. Abraham Cowley was its inventor, attracted mainly by the freedom of expression its structurelessness afforded. Dryden

and Pope wrote pindarics, and among numerous lesser poets Oldham, Mrs Behn, Otway, Sprat, Flatman. Following Congreve's exposure in his *Discourse on the Pindarique Ode* (1706) of the misconception upon which the pindaric was based more shape was given to the form. But even in the odes of Wordsworth, Shelley, and Coleridge, in a broken versification, traces of the 'vicious tradition' are to be seen. Or odes written in just imitation of Pindar, memorable examples are furnished by Congreve and by Gray, and Tennyson's 'Ode on the Death of the Duke of Wellington' is among the latest noteworthy odes of the kind. See ODE.

Pindaris, bands of unpaid freebooting horse-soldiers who, after the overthrow of the Mogul empire of India, grew (1804-17) to be a formidable power in the Central Provinces, their headquarters being at Malwa. Hastings, to put an end to their depredations, gathered two armies (120,000 men in all) in 1817 and crushed them. See R. G. Burton, *The Mahratta and Pindari War* (1910).

Pind Dadan Khan, a town in the Punjab, stands one mile N. of the Jhelum and 110 miles NW. of Lahore. The people (10,000) make brass and copper utensils, pottery, whips, boats, and woollens, and carry on a large trade.

Pindus. See GREECE.

Pine (*Pinus*), a genus of trees of the family Coniferae (q.v.). Pines is distinguished by monocious flowers, and woody cones with numerous two-seeded scales, the scales having an angular truncated apex. The leaves are linear and very narrow, growing in clusters or in pairs, and surrounded by scarious scales at the base. To this genus belong many noble and useful trees. They mostly grow in mountainous or other exposed situations, and their narrow leaves are admirably adapted to evade the force of winds, which produce in the tops of pines a peculiar sound, much noticed by the ancient poets, more soft and continuous than in trees of richer foliage. Most of the pines are more or less social, one kind often covering a considerable tract; some of them clothing the sides and even the summits of mountains with magnificent but sombre forests; some growing in lower situations, on otherwise unproductive sandy grounds, as the *Pine Barrens* of North America. The pines growing in the most barren soils, or in the coldest climates and most exposed situations, are often very small, and, although very unlike any other shrubs or bushes, are scarcely to be called trees. Pines are widely diffused over the northern hemisphere, being found on mountains within and near the tropics, and in the colder temperate and the arctic regions descending to the level of the sea.

The Scots Pine (*P. sylvestris*), commonly but erroneously known as the Scotch Fir, is the only species indigenous to Britain. It has leaves in pairs, two to three inches long, the cones about the same length, obtuse, and with unarmd scales. On very poor soils and at great elevations it is reduced to a kind of shrub, but in favourable situations it becomes a lofty tree. A plank five feet and a half in width has been obtained from a Scottish forest. The Scots pine is of quick growth, but has been known to attain the age of 400 years. Its head is somewhat conical or rounded, and the lower branches die off as the tree grows, leaving the older trees bare of branches for the greater part of their height; but it is more apt to send off large branches than most of the Coniferae. There are still native forests of Scots pine at Braemar and elsewhere in the Highlands; and even in the south of Scotland noble trees are to be seen which, probably, were not planted by man. The Scots pine is not indigenous to

the south of England, but, having been introduced, has spread rapidly and spontaneously, along with the *Pinaster*, in some of the heaths and other unfertile tracts. Immense forests of it exist in some countries of Europe, in some of which it is mingled with the Spruce Fir. In the middle and north of Europe and of Asia it is found even in plains near the level of the sea, especially where the soil is somewhat sandy; in the south of Europe

Fig. 1.—Scots Pine (*Pinus sylvestris*):

a, young shoot with female flower; b, twig with male flower; c, female flower; d, ripe cone; e, the same, opened; f, pair of needles with section.

it grows only on mountains. Its timber is highly valuable, being very resinous and durable, and is the *Red Deal* or *Red Pine* used in house and ship carpentry. There is a very great difference, however, in the timber of Scots pine growing in different soils and situations, rich soils and sheltered situations being unfavourable. One of the best varieties is that which forms the northern Scottish forests, remarkable for its very horizontal branches. The Scots pine is not only valuable for its timber. Common Turpentine is obtained from it, and much Tar, Pitch, Resin, and Lampblack (see these heads). Oil of turpentine is sometimes distilled from the cones, and even from the leaves; the leaves have also been used for the manufacture of Pine-wool (see FIBROUS SUBSTANCES). The inner bark, when most soft and succulent in spring, is by the Kanchadales and Laplanders dried, ground, steeped in water to remove the resinous taste, and used for making a coarse kind of bread.

The Dwarf Pine (*P. montana*, or *P. Pamilio*) is found on the Alps and Pyrenees, its trunk often lying on the ground, although sometimes it appears as a bush or low tree. The leaves are in pairs, very like those of the Scots pine, but a little longer; the cones are also similar. The resin spontaneously exuding from the tree is known as *Hungarian Balsam*. The Aleppo Pine (*P. halepensis*), a native of the south of Europe, Syria, &c., is a very graceful tree of moderate size, with leaves in pairs and slender. The *Laricio* (*P. Laricio*) has leaves in pairs, lax, and 4 to 8 inches long, cones 2 to 4 inches long, with the scales slightly pointed. It is often called the Corsican Pine. It grows on the shores of the Mediterranean, and is valuable for its timber and resinous products. In Corsica it frequently attains the height of 140 feet. It grows well in sandy soils, and has been made particularly useful for preventing the drifting of sand,

and turning to account the otherwise useless tracts between the mouths of the Garonne and the Adour, thus also preserving valuable lands which the sand threatened to overwhelm. Of its varieties the Austrian or Black Pine (*P. Laricio nigricans*, or *P. austriaca*), with light-gray buds, thick dark shaggy foliage, and great spread of branches, abounds in resin more than any other European tree; and *P. Laricio Pallasiana*, with bristling needles, abundant cones, and heavy branches, is a good tree for ill-drained peaty soils. The *Pinaster* or Cluster Pine (*P. Pinaster*) is another of the most important European species. It is a big tree, with cones in groups sometimes of 20 or more, 4 to 6 inches long, leaves in pairs, and very long. It is found on the shores of the Mediterranean, and also in the Himalayas and in China. It has been used in France to a great extent, in the same way as the *Laricio*, for covering waste sandy tracts. The timber is inferior. The Stone Pine (*P. Pinea*), a tree with a broad umbrella-shaped head, a form often seen also in the Scots pine, forms a characteristic feature of the scenery of the Mediterranean. It is the *Pine* of the Germans, the *Pignon* of the French. The leaves are in pairs, 4 to 5 inches long, the cones very large, ovate, and obtuse. The seeds, which do not ripen till the fourth year, are large, abound in a fixed oil, and, when fresh, have a sweet taste resembling that of almonds. They are used like

Fig. 2.

cones of (a) *Pinus montana*; (b) *P. Pinaster*; and (c) *P. Pinaster*. Cones and needles of (d) *P. Coulteri*; and (e) *P. Lambertiana*. All about 1/2 natural size.

almonds and pistachio nuts, but very soon become acid. The wood is very beautiful. The *Cembra* pine, or Swiss Stone Pine (*P. Cembra*), which grows in the central parts of Europe and the south of Siberia—a stately tree, with the lower branches more persistent than they are in most pines, and rigid leaves in groups of three to six, commonly five—also produces eatable seeds (*Cembra Nuts*).

North America produces many species of pine, one of them very beautiful and very valuable. The Red Canadian Pine (*P. resinosa*) is found from Canada to the Pacific, but does not reach as south in the United States. It is the Yellow Pine of Canada and Nova Scotia. It delights in dry and sandy soils, and attains a height of 70 to 80 feet, with a diameter of 2 feet at the base, the trunk continuing of uniform diameter for two-thirds of its length. The leaves are in pairs, and

etc. congregated towards the extremities of the branches. Somewhat resembling this in botanical characters is the Scrub Pine, or Gray Pine (*P. Banksiana*), generally only 3 to 10 feet high, which begins to appear in the northern parts of the United States upon high mountains, and is interesting as an arctic species, extending farther north than any other. The Yellow Pine (*P. variabilis*, or *P. mitis*) abounds in the Atlantic states from New Jersey to Virginia. It is a tree 50 to 60 feet high, 15 to 18 inches in diameter at the base, with leaves 4 to 5 inches long, usually in pairs, but sometimes in threes upon the younger shoots. For timber it is one of the most valuable of American pines. The Jersey Pine, or Scrub Pine (*P. inops*), abounds in the lower parts of New Jersey, and thence to the south-west. The leaves are in pairs, 1 to 2 inches long, the cones armed with strong spines. The tree is rarely 30 or 40 feet high. *P. rigida*, a native of the northern and middle parts of the United States, shares the name of Pitch Pine with several others. The leaves are in threes, varying much in length, as the cones do in size. The Loblolly or Old Field Pine (*P. Taeda*) grows in dry and sandy soils in the lower parts of the southern states, often occupying lands exhausted by cultivation. Vast tracts never cultivated in the southern states are *Pine Barrens*, in great part covered with this species of pine. It attains a height of 80 feet and upwards, and has a wide-spreading crown. The leaves are 6 inches long, in threes, sometimes in fours on young branches; the cones 4 inches high, with strong spines. The timber is not of much value. The Pitch Pine, Long-leaved Pine, or Southern Pine (*P. palustris*, or *P. australis*), is perhaps the most important of North American forest trees. It furnishes the greater part of the tar, resin, pitch, and turpentine used in the United States. The timber is also very valuable. The tree attains a height of 60 to 70 feet, and a diameter of about 16 to 18 inches; the leaves are in threes, and about a foot long, the cones 7 to 8 inches long, and 4 inches in diameter, with small spines. The seeds are sometimes eaten. The White Pine (*P. Strobus*), called in Britain the Weymouth Pine, from its having been largely planted by Lord Weymouth, attains a height of 150 feet, and a diameter of 5 feet and upwards. It has lax sub-triangular leaves in groups of five, and pendulous cones 4 to 8 inches long, with thin smooth scales. It is frequently planted in Britain and on the continent of Europe for its beauty. In its native country it abounds chiefly from lat. 47° to lat. 43°, and southward to the Alleghanies. The timber is not strong, but easily wrought and durable. Of the species belonging to the north-western parts of America one of the most magnificent is *P. Lambertiana*, which is found on the Rocky Mountains between lat. 40° and lat. 43°, chiefly on sandy soils. It attains a height of 150 to 200 feet, and a diameter of 7 feet and upwards, almost to 20 feet. The trunk is remarkably straight, and destitute of branches for two-thirds of its height; the leaves in fives, the cones upwards of a foot long. The timber is white, soft, and light; and the tree produces great quantities of a pure amber-coloured resin, which, when the wood is partly burned, is changed into a somewhat saccharine substance, used by the Indians as a substitute for sugar. The seeds are eaten either roasted or pounded into coarse cakes. *P. flexilis* is found on the Rocky Mountains, and occurs almost to the limit of perpetual snow. It has a dense crown formed of numerous and remarkably flexile branches. The leaves are in fives. *P. ponderosa*, another native of the Rocky Mountains, is a magnificent tree, remark-

able for the heaviness of its timber, which almost sinks in water. The leaves are in threes, and 9 to 14 inches long. *P. Sabiniiana*, *P. Coulteri*, and *P. insignis* are also noble species from the west of North America.

The Himalayas abound in pines, some of which rival in magnificence those of North-west America. The Bhutan Pine (*P. excolsa*), much resembling the Weymouth Pine in its botanical characters, and attaining a height of 90 to 120 feet, abounds in Bhutan. The Cheer Pine (*P. longifolia*) of India is a tree of remarkable and most graceful appearance, with leaves in threes, very long, very slender, and generally pendulous. It is abundant on the crests of hills in the lower Himalayas, growing at a lower elevation than the other pines. *P. Gerardiana*, a species with leaves in threes, is a large tree, a native of Nepal.

The term pine is in general use for the timber of the pine-tribe (see CONIFERÆ), and is not confined to that of the genus *Pinus*, but embraces the wood of species of *Abies*, *Larix*, *Araucaria*, *Agathis*, &c., and even of *Callitris* and *Dacrydium* of the Cypress tribe. From the Baltic ports come red wood and white wood. The former is yielded by the Scots Pine (*Pinus sylvestris*), and the latter by the Spruce Fir (*Abies excelsa*). These two, with the Larch (*Larix europæa*), yield the greatest part of the pine-timber of Europe. See TIMBER.

Pineal Gland, a small reddish body at the end of an upgrowth from the optic thalami in the vertebrate brain. It is about the size of a pea in man, and rests on the corpora quadrigemina (see BRAIN). It consists of epithelial cells, a few atrophied nerve-cells, and salt deposits ('brain sand'). Descartes regarded it as the seat of the soul. Its stalk sometimes gives rise to a 'parietal organ,' which may also arise separately from the brain-roof, and in some forms, notably in the New Zealand *Sphenodon* (q.v.), this parietal organ assumes a remarkable eye-like structure, as if it were a vestigial unpaired eye.

Pine-apple, or ANANAS, genus of Bromeliaceæ, highly esteemed, and much cultivated for its fruit. The fruit is a *sorosis*, formed by the calyces and bracts of a close spike of flowers, becoming succulent

Pine-apple (*Ananas sativus*).

and combined. This is the distinctive character of the genus *Ananas*. The pine-apple has a number of long, serrated or smooth-edged, sharp-pointed, rigid leaves, springing from the root, in the midst of which a short flower-stem is thrown up, bearing a single spike of flowers, and therefore a single fruit. From the summit of the fruit springs a crown or tuft of small leaves, capable of becoming

a new plant; the pine-apple, in cultivation, being propagated entirely by crowns and suckers, as, in a state of high cultivation, perfect seed is almost never produced. The various cultivated forms spring from two species, *A. sativus* and *A. bracteatus*. These are found wild in sandy maritime districts in the north-east of South America. The pine-apple has also been gradually diffused over tropical and subtropical countries, and not only as a cultivated plant, for it is fully naturalised in many parts both of Asia and Africa, and has even been adopted as a kind of armorial bearing by the Luwu people of Central Celebes. It delights in a moist climate, and consequently does not succeed well in the dry climate of the south of Italy, although the warmth is sufficient. The first particular account of the pine-apple was given by Oviedo in 1533. It was in Holland that it first began to be cultivated in hothouses; but it was introduced into England from that country in 1690, and first cultivated by Mr Bentinck, ancestor to the ducal family of Portland; and its cultivation rapidly became general in the gardens of the wealthy. It was only after the peace of 1815 that it received similar attention in continental Europe. Later in the century, however, with improvements in means of transportation, the pine-apple disappeared as an important British and European hothouse crop. To-day among leading sources of supply are the Azores, Canary Islands, Hawaii, Florida, Straits Settlements, Queensland. Great care is requisite in the cultivation of the pine-apple, which without it is generally fibrous and coarse, with little sweetness or flavour, and with it one of the most delicate and richly flavoured of fruits. Its size, too, very much depends on cultivation, but there is also considerable difference in the size of the fruit in different varieties, the largest not being always the most luscious and superior in flavour. The size varies from 2½ lb. to 12 lb. in weight.

A spirituous liquor (*Pine-apple Rum*) is made from the pine-apple in some warm countries. The use of the fibre of the pine-apple is noticed in the articles BROMELIACEÆ, FIBROUS SUBSTANCES. For Pine-apple Oil, see BUTYRIC ETHER.

Pine-beetle. See BARK-BEETLES.

Pine Bluff, capital of Jefferson county, Arkansas, is built on a high bluff on the south bank of the Arkansas River, at the head of low-water navigation, about 120 miles from its mouth. Cotton and lumber are the staples of trade, and among industrial undertakings are cotton seed oil mills, cotton gins, saw-mills, stave and spoke factories; also foundries, brickworks, &c. Pop. 19,000.

Pinel, PHILIPPE (1745-1826), a Parisian physician who gained for himself undying fame by his reformation of the old barbarous methods of treating the insane.

Pinero, SIR ARTHUR WING, English playwright, was born in London, of Portuguese-Jewish ancestry on his father's side, 24th May 1855. He studied law, but in 1874 made his *début* on the stage at Edinburgh, and, without any notable success, continued actor (in 1876-81 in Irving's Lyceum Company) till 1884, when he left the stage to devote himself to playwriting, in which he had already achieved first successes. His earliest plays of importance were *The Money Spinner*, of 1881, and *The Squire* of the same year. Both were serious plays, but later came successes in farce, as *The Magistrate* (1885), *The Schoolmistress* (1886), *Dandy Dick* (1887), and in comedy, sometimes sentimental, as *Sweet Lavender* (1888), *The Weaker Sex* (1889), sometimes satirical, as *The Hobby-Horse* (1886), *Lady Bountiful* (1891); by this work Pinero revealed himself as a master of the technique of English comedy, and by some comedy

has been held to be his most characteristic form. *The Profligate*, of 1889, however, brought a return to the serious drama, and in 1893 appeared the epoch-marking problem play, *The Second Mrs Tanqueray*; by it the English drama of the time was given a European standing, and Pinero was placed among the first rank of living dramatists. Numerous plays followed, displaying a remarkable versatility. Of the number were the serious dramas *The Notorious Mrs Elphinstone* (1895), *Mid-Channel* (1909); the comedies *The Gay Lord Quex* (1899), *Letty* (1903), *His House in Order* (1906), *The 'Mind the Paint' Girl* (1912); also the idyll *The Freaks* (1918), the wordless play, *Monica's Blue Boy* (1918, with music by Sir Frederic Cowan), and the fable *The Enchanted Cottage* (1922). Pinero was knighted in 1909. See a work by H. Hamilton Fyfe (1902).

Pinerolo, or PIGNEROL, a town of North Italy (formerly in Savoy), 23 miles S.W. of Turin. In its strong citadel, then regarded as the key of Italy, the Man with the Iron Mask, Lauzun, and Fougnet were imprisoned. This fortress was in French hands from 1536 to 1574, again from 1630 to 1696, from 1704 to 1706, and from 1801 to 1814. The town contains a cathedral and a cavalry school. Cloth, paper, leather, cotton, and silk are manufactured. Pop. 19,000.

Pine-tree Money, silver money coined at Boston, Massachusetts, in the 17th century (from 1652), and so called from the coins' bearing the rude figure of a Weymouth pine (*Pinus Strobus*) on one side. The date 1652 was retained, though there were changes in the dies.

Pine-wool. See FIBROUS SUBSTANCES.

Ping-pong, or TABLE-TENNIS, a miniature form of lawn-tennis played on a table indoors. The ball, of light celluloid and hollow, is about 1½ inch in diameter. The racket is usually of wood generally covered with vellum, cork, sand-paper, or rubber: from the sound of play with the original hollow vellum-covered racket the onomatopoeic name—a trade name—of the game was derived. While the general conception of the game corresponds to that of lawn-tennis, there are important differences in detail. The game was invented in England, or in India by Englishmen, and dates from the close of the 19th century, when the introduction of celluloid balls made it possible. At first it was known as 'gossima.' In 1900-2, as 'ping-pong,' it became a rage in Great Britain and also in the British colonies, and in France and America. But presently the craze disappeared. In 1922, however, a revival took place. Since then the ruling authority of the game has been the Table Tennis Association, the heir, because of difficulties arising out of the use of the trade name, not of the original Table Tennis Association, but of its contemporary and rival the Ping-Pong Association.

Pink (*Dianthus*), a genus of Caryophyllaceæ, of which there are some 300 species, annuals and perennials, with beautiful and often fragrant flowers, chiefly natives of Europe and temperate Asia. The calyx is tubular, 5-toothed, with two or four scales at the base; there are five petals suddenly contracted at the throat of the corolla into a linear claw. There are ten stamens, and one ovary with two styles. The capsule is cylindrical and one-celled. The exquisite beauty of the flowers has attracted admiration in all ages; and some of the species have long been much cultivated in gardens, particularly the Garden Pink and Carnation (q.v.), which are often referred to one original, the Clove Pink (*D. Caryophyllus*), a native of the south of Europe, growing wild on rocks and old walls, and naturalised in some places in the south of England; whilst some botanists refer the garden

pinks with more probability in part to the Maiden Pink (*D. deltoidea*), a British species, and those called Pheasant-eye pinks to the Feather Pink (*D. plumarius*), a native of some parts of continental Europe naturalised in England. The varieties of the garden pink and the pheasant-eye pink, which are usually designated the florists' pink, are of much less antiquity than the carnation as garden ornaments. Gerard scarcely mentions them, while in Parkinson's time they appear only to have been cultivated as other hardy perennials and annuals were, without any special care. Their capabilities as choice florists' flowers were recognised about 1810, and the number of varieties has since then greatly increased. Nearly allied to them is *D. superbus*, found in moist places in some parts of Europe, and not unfrequently to be seen in flower-borders. It has very fragrant flowers. Both single and double pinks are generally propagated by *pupings*, which are short cuttings of the younger shoots. They are also sometimes propagated by layers. A rich loamy soil is the best for pinks. The Maiden Pink is a small, much-branched plant, growing in grassy places, on gravelly and sandy soils; it has rose-coloured flowers spotted with white, and a white eye encircled by a deep purple ring. The very rare Cheddar Pink (*D. carvius*) grows on the limestone cliffs of Cheddar. The Deptford Pink (*D. Armeria*) and the Clustered Pink, or Chidding Pink (now placed in another genus, as *Twinea prolifer*), also natives of England, differ from those in being annuals, and in having clustered flowers. The Bearded Pink, or Sweet William (*D. barbatus*), with bearded petals, has long been a favourite garden-flower. The choice Mule Pink, or Fielding's Pink, is supposed to be a hybrid between Sweet William and Picotee. The Indian Pink, or China Pink (*D. chinensis*), is now common in flower-gardens. Although perennial, pinks are sown annually by florists to secure fine flowers.—*See-pink* is a common name of Thift (q.v.).

Pinkerton, ALLAN (1819-84), born in Glasgow, became a Chartist, but in 1842 emigrated to Chicago, where he organised a famous detective agency, which developed into a kind of private mercenary army (armed with rifles, revolvers, and shot-proof shelters), suppressed the Molly Maguires (q.v.), and was conspicuous in labour troubles, as at Homestead in 1892. He wrote several books on his triumphs.

Pinkerton, JOHN, an acrid little book-maker, born at Edinburgh in 1758, who, after five years' irksome apprenticeship to a lawyer, in 1780 settled in London as a man of letters, in 1802 in Paris, where he died in indigent circumstances, 10th May 1826. His twenty-four works and compilations include some pseudo-archaic 'rimes,' ballads, &c.; *Essay on Medals* (1784); *Letters of Literature* (1785), marked chiefly by a novel system of inflection and orthography; *Ancient Scottish Poems from the MS. Collections of Sir Richard Maitland of Lethington* (1786); *Dissertation on the Origin and Progress of the Scythians or Goths* (1787), in which he first fell foul of the whole Celtic race; *Enquiry into the History of Scotland preceding the Reign of Malcolm III.* (1790); *Iconographia Scotica* (1795-97); *History of Scotland from the Accession of the House of Stuart to that of Mary* (1797); *Walpoliana* (1799); *Modern Geography* (1802-1807); *Voyages and Travels* (16 vols. 1808-13); *New Modern Atlas* (1809-15); and *Petrology, or a Treatise on Rocks* (1811). See his *Literary Correspondence* (2 vols. 1830).

Pink-eye, a contagious and infectious disease of horses. The primary symptoms are loss of appetite, dullness, perhaps rigors, with fever (tem-

perature varying from about 104° to 107°, or, in very severe cases 108° F.). In slight cases the pulse may be 65, in very severe ones over 100 beats a minute. These symptoms are succeeded—but not always—by swelling of the eyelids and redness of the eye—hence the term pink-eye—pain in and stiffness of the limbs, with tumefaction, particularly around the joints. The swellings are at first limited, but soon extend upwards and downwards from the joints affected, and their occurrence gives rise to the pain. The digestive organs are disturbed; there is generally constipation at first, the feces are covered with mucus, and in many instances there is some degree of colicky or intestinal pain. Some horses have a loud, hoarse cough, at first dry, but often becoming moist; but lung complications are not very common. In some instances the pulse gradually becomes very feeble, though the animal presents no other bad symptom, the pain having left the limbs, the appetite returning, the swellings diminishing, and the secretions regaining the normal condition; whilst an ordinary observer is confident of a rapid recovery, the animal suddenly dies, and a post-mortem examination reveals the presence of ante-mortem clots of blood in the cavities of the heart, and perhaps in the great pulmonary blood-vessels. To the veterinarian the apparently convalescent stage is a most critical condition, and he must endeavour, by rousing the heart's action, to prevent the formation of these coagula.

As a rule the disease runs its course favourably in from four to ten days, leaving the animal with more or less loss of condition and strength, but both are soon restored by good nursing (a comfortable roomy airy loose-box, warm clothing if necessary, great attention to diet) and gentle exercise. The treatment which has proved most successful is based on the conclusion that the disease runs a definite course, and that attempts to check it do more harm than good. It is dangerous to work a horse with this disease after he has manifested the slightest loss of appetite; many horses turned out to work after failure of appetite have been brought back a few hours after in a dying condition. The medicines made use of are those which moderate pain if excessive, keep the contents of the stomach and bowels from undergoing putrefactive fermentation, and act as very slight aperients; and, when the heart's action threatens the condition above described, cardiac stimulants, such as the carbonate of ammonia given in a ball. Alcoholic stimulants, in virtue of their irritating properties and their effect on the nervous system, are very injurious, and should not be administered in this nor in any other disease where the so-called fibrinous state of the blood is one of the conditions.—The name Pink-eye is also given to a red discoloration in salted food, especially fish, due to the use of salt contaminated by a 'red coccus' and another organism.

Pinkle, a battle fought on 10th September 1547 near Musselburgh in Midlothian between 14,000 English under the Protector Somerset and twice that number of Scots. The latter were utterly defeated, more than 10,000, it is said, being killed on the field and in the pursuit, whilst the English loss was barely 200.

Pink Root. See SPIGELIA.

Pinna, a genus of bivalves, not far removed from mussels (*Mytilida*). The shell is acutely triangular, beautifully translucent, and in some species measures two feet in length. The attaching byssus, especially of the Mediterranean species (*P. nobilis*), is very long and silky, and admits of being woven into fabrics. So the ancients occasionally used it, and, to gratify the curious, byssus-gloves,

See, are still made at Taranto and elsewhere. The animal is sometimes eaten. It lives from low-water to sixty fathoms.

Pinnacle. See BOAT.

Pinnacle, a termination of tapering form crowning some architectural member. It did not become common till the Gothic period, when it became a highly-important decorative element. See GOTHIC ARCHITECTURE.

Pinnipedia. See SEAL.

Pinnock, WILLIAM (1782-1843), once famous as the originator of the catechisms which bear his name, was born at Alton in Hampshire. The catechisms consisted of short popular manuals on almost every conceivable subject, arranged in the form of question and answer. They were produced in association with his brother-in-law, Samuel Mauder (q.v.), and finally extended to 12 volumes, or 83 separate parts. Histories of England, Greece, and Rome ran through more than a hundred editions. Before his death in London he had lost nearly all his wealth in speculation.—His son, WILLIAM HENRY PINNOCK, LL.D. (1813-85), vicar of Pinner, studied at Cambridge, and wrote on church law and church history.

Pinos, ISLA DE, an island in the West Indies, south of Cuba, of the Havana province of which it forms part. It was discovered by Columbus in 1494, has an area of 1200 sq. m., part low and swampy, and part hilly (1500 feet), and is clothed with fine meadows and woods (it takes its name from *Pinus cubensis*), and produces fruit, and silver, quicksilver, and iron. It was once notorious as the resort of pirates.

Pins. The earliest kinds of pins were probably thorns or fish bones. Prehistoric pins of bone and bronze are common, and copper and iron pins also occur. Munro estimated that 10,000 pins had been collected at the lacustrine stations of Switzerland alone. They seem to have been chiefly used as hair-pins, though no doubt they were also employed to fasten the dress, and for other purposes. The forms of these ancient pins are extremely varied, and in the numerous cases where they have ornamented heads the patterns are often curious and beautiful. A good many both of bone and of bronze have a head formed of a loose ring in an eye. Some have bulbous heads (these occasionally being of amber). For numerous illustrations of ancient pins, see Munro's *Lake-dwellings of Europe* (1890). Among articles for the toilet found in Egypt some pins with gold heads occur, and ancient Roman bronze pins and bone hair-pins, with ornamental heads, have been found at Pompeii. About 1840 the solid-headed kind now in common use took the place of the older form of pin, which had a globular head of fine twisted wire made separately and secured to the shank by compression from a falling block and die. These old pins had the disadvantage of frequently losing their heads. They were made by manual labour in such a way that each pin passed through the hands of fourteen different persons (see DIVISION OF LABOUR). Solid-headed pins are made by an improved form of a machine which was patented in England by an American, named L. W. Wright, in 1824. Pincers draw from a reel of wire a length sufficient to make a pin, which is at the same time straightened by passing between fixed studs. The pin length is seized by lateral jaws, from which a portion of the wire is left projecting. A snap head die next advances to shape the head partially; the jaws or grippers then release it, and the pin is pushed forward again about a twentieth of an inch, when the head gets another squeeze of the die. These movements of the machine are repeated once more to finish the head, and the wire is then cut

to the length of a pin. The headed blanks drop into a receptacle and arrange themselves in the line of a slot formed by two inclined and bevel-edged bars. The opening between the bars is just wide enough to let the shank of the pin fall through. From the lower end the blanks are passed along, rotating as they move, in front of a cylindrical cutter, which files them to a point.

Ordinary pins are made of brass wire, and after cleaning are coated with tin, or 'coloured,' as it is called. For black pins iron wire is used, and these are either 'blued' by heating in a muffle or varnished. Safety-pins, with the point resting in a loop, were already made in prehistoric times.

Pinsk, a town ceded by Ukraine to Poland by the treaty of Riga, 1920, stands in the midst of what were formerly vast marshes (in large part drained since 1875), on a branch of the Pripet, 98 miles by rail E. of Brest-Litovsk. It manufactures leather and has a large transit trade. Pop. 36,500, two-thirds being Jews.

Pinsuti, CRO (1829-88), composer of over 300 songs, was born at Sinalinga in Tuscany. He studied music at Bologna (1845), and was a special pupil of Rossini. From 1848 to 1885 he taught singing in England, chiefly at London and Newcastle, from 1856 at the Royal Academy of Music.

Pint, a measure of capacity used both for liquids and dry goods, and equivalent to the eighth part of a Gallon (q.v.), or 34.65925 cubic inches. The Scots pint, superseded as a legal measure by the imperial pint, was equal to 3.0065 imperial pints.

Pintado. See GUINEA FOWL.

Pintail (*Dafila*), a genus of ducks, widely represented in northern regions. One of the species, *D. acuta*, also called the Sea Pheasant because of its elongated form, is a regular winter visitor to

Pintail Duck (*Dafila acuta*).

Great Britain, and has established itself as a breeding species in some parts of Scotland. It often crosses with the mallard. The flesh is very palatable.

Pinto, FERNÃO MENDEZ, Portuguese adventurer, born at Montemor-o-Velho, near Coimbra, about 1510. When twenty-seven years of age he made his way out to India, and remained twenty-one years in the south and south-east of Asia, leading the life of an adventurous seaman, fighting pirates at one time, trading at another, and again being employed on special missions to Japan or elsewhere. His fortune often fluctuating between great wealth and poverty. He returned home to Portugal in 1558, spent much time in writing an account of his adventures, adding to them many exaggerations and gross fictions, and died at

Almada near Lisbon, probably in 1583. His travels—*Peregrinacão*—were not published until 1614, but have since then been translated into several European languages—into English by F. Cogan in 1663 (abridged with introduction by A. Vambéry, 1891).

Pinturicchio, whose proper name was BERNARDINO DI BETTI, was a painter, born at Perugia, in 1454. An assistant to Perugino, he helped him with the frescoes in the Sistine Chapel at Rome, and then spent the best part of eight years (1484–92) in painting frescoes on the walls of the chapels of Santa Maria del Popolo in Rome. After executing two pieces in the cathedral at Orvieto he decorated the walls of what is now the Vatican Library with a series of six frescoes; this occupied him six years (till 1498). On the walls of Sta Maria in Ara Cœli he illustrated the life of St Bernardino of Siena. Other frescoes by his brush adorned two churches in Spello, the Petrucci Palace at Siena, and the cathedral library in the same city, this last series illustrating the life of Pope Pius II. All these works are admirable examples of decorative art. Pinturicchio painted a few panel pictures of high merit, as Christ bearing the Cross, two Madonnas enthroned (at Perugia), Coronation of the Virgin (in the Vatican), and others at Siena, Florence, and Spello. He died at Siena, 11th December 1513.

See *Life* by Vermigholi (1837), books by Schmarsow (1880–82) and E. M. Phillips (1901), but especially *Pinturicchio: his Life, Work, and Time*, by Corrado Ricci (trans. 1902).

Pinwell, GEORGE JOHN (1842–75), born in Wycombe, drew on wood, did book illustration, and after 1865 became a water-colour painter. Dying young, he left few works, but the promise of these was great. See *Life* by G. C. Williamson (1900).

Pinzon, a wealthy Andalusian family, of which three brothers who flourished in the 15th and early 16th centuries were associated with Columbus in the discovery of America. On Columbus's first voyage (1492) MARTIN ALONZO commanded the *Pinta*, but did not remain loyal to his leader; FRANCISCO was pilot of the *Pinta*; and VICENTE YAÑEZ commanded the *Niña*. On an independent voyage Vicente Yañez discovered Brazil (q.v.).

Piombi, the notorious roof-cells (*sotto i piombi*, 'under the leads') of the state-prisons of Venice (q.v.), in which Casanova and many other notable prisoners were confined.

Piombino, a former principality of Italy, lies along the coast opposite the island of Elba, the greater part of which belonged to it. Its extent was 139 sq. m.; and its population, previous to its incorporation with Italy in 1860, about 25,000. Piombino, originally a fief of the empire, came in the 14th century into the possession of the Appiani, who, after ruling it for nearly 200 years, made way for the Buoncompagni, who were expelled by Napoleon in 1801; but after the Congress of Vienna the principality was put under the suzerainty of Tuscany. The town of Piombino (pop. 24,000), at the S. end of a promontory 50 miles S. of Leghorn, has iron-rolling mills and is the port of embarkation for Elba. At the N. end of the promontory was the ancient Etruscan city of Populonium: considerable remains of its walls exist, and numerous Etruscan tombs have been found.

Piombo. See SEBASTIAN DEL PIOMBO.

Pioneer, in the British infantry, is a military artisan employed during peace in such work as painting and repairing barrack-rooms, &c., and in war marching at the head of each battalion with

tools to clear a passage for it through woods or other obstructions, improve roads, make bridges, and generally to do any minor engineering or constructive work that may be necessary.

Cavalry Pioneers are instructed at the School of Military Engineering, Chatham, in the best method of rapidly destroying railways, telegraph lines, &c., and carry gun-cotton and the tools necessary for this purpose. Abroad, and in the Indian army, there are whole battalions called pioneers, who are nothing less than lightly-equipped engineers, but who also fight like infantry.

Piotrkow (Ger. *Petrikau*), a town of Poland, 87 miles by rail S.W. of Warsaw. There are various industries—leather, textiles, founding, saw and flour milling. It is one of the oldest Polish towns; here in the 15th and 16th centuries diets were held and the kings elected. Pop. 41,000.

Piozzi, MRS, more famous as MRS THRALE, and by that name to be remembered until Dr Samuel Johnson is forgotten. Her maiden name was Hester Lynch Salusbury, and she was born of a good Welsh family at Bodvel in Camarvanshire, 27th January 1741. She early gave promise of quick parts and lively disposition, and received a good education. Early introduced into the fashionable world of London, in October 1763 she married Henry Thrale, a prosperous Southwark brewer, thirteen years her senior. She bore him one son and eleven daughters, the eldest Dr Johnson's 'Queenie.' Thrale was an honest man, an indulgent, if somewhat indifferent, husband, uncommunicative and phlegmatic in temperament. Mrs Thrale made Johnson's acquaintance through the kind offices of Arthur Murphy (q.v.) in January 1765, and one of the most interesting friendships in the history of letters at once began. The sage quickly conceived an extraordinary affection for his 'mistress,' was domiciliated in her house at Streatham Place for over sixteen years, and for her sake learned to soften many of the eccentricities of his speech, dress, and behaviour. Thrale himself had esteem for Johnson, carried him with the family to Brighton, to Wales in 1774, and to France in 1775, and left him £200 as one of his four executors. Thrale died in April 1781, and three years later the brewery was sold for £135,000. Dr Johnson's health was now declining, and he soon began to feel himself slighted as the widow's affection for the Italian musician Piozzi began to occupy her heart. A few letters on the subject of the proposed marriage passed betwixt Johnson and herself, in which it must be confessed that the woman shows to more advantage than the sage. The marriage, for some time postponed owing to the objections of her daughters and her friends, took place at Bath, 25th July 1784, and the pair travelled through France, Italy, Germany, and Belgium, returning to England early in 1787. Piozzi proved an inoffensive husband and managed their finances with prudence. Mrs Piozzi returned to Streatham in 1790, but soon after built Brynbell in the banks of the Clwyd. Here Piozzi died in 1809, and here his widow remained till 1814, living thereafter at Bath, Clifton, and Penzance. When past seventy she formed a sentimental attachment for William Augustus Conway, a handsome young actor, who drowned himself crossing the Atlantic in 1828. She died at Clifton, 2d May 1821.

Mrs Thrale was vivacious, frank, witty, thoroughly feminine, and charming, if somewhat wanting in refinement. She was pretty, if hardly beautiful—her face gave Hogarth his model in 'The Lady's Last Stake,' but the best portrait is that by Sir Joshua Reynolds. Baretti, Boswell, Wolcott, Gifford, and Horace Walpole all abused her; but she lives secure of immortality in the love of Samuel

Johnson, and in the happiness she brought into nearly twenty years of a life 'radically wretched.'

Mrs Prozzi had a fatal facility in composition, but two of her books at least live through their subject, and indeed are only less interesting than Boswell himself: *Anecdotes of Dr Samuel Johnson during the last Twenty Years of his Life* (1796, ed. with introduction by S. C. Roberts, 1925), and *Letters to and from Dr Samuel Johnson* (2 vols. 1788). Her *Observations and Reflections made in a Journey through France, Italy, and Germany* (2 vols. 1789), *British Synonymy* (2 vols. 1794), and *Retrospection, or a Review of the most striking and important Events, &c.* (2 vols. 1801) are long forgotten. Of her poems the 'Three Warnings' survives—it was first printed in the *Miscellanies* of Miss Williams (1766), a volume containing a prose-tale of Johnson's, 'The Fountains,' the heroine of which, Floretta, was a study of Mrs Thrale. Her notes to Wrayall's *Historical Memoirs* were reprinted in the 1884 edition of that work, as well as in Hayward. Her *Autobiography, Letters, and Literary Remains* were edited with notes and an account of her life by Abraham Hayward, in 1861 (2 vols.); and selections from this work were edited with introduction and notes by J. H. Lobbart as *Dr Johnson's Mrs Thrale* (1909). *Thraliana*, a 6-volume MS. partly in diary form and covering the years 1775–1809, was begun by Mrs Thrale at Johnson's suggestion, and records many conversations, anecdotes, &c. of Johnson and his friends; C. Hughes's *Mrs Prozzi's Thraliana* (1913) gives many extracts hitherto unpublished. See further the Rev. E. Mangin's *Piozziana* (1833), Boswell's *Life of Johnson*, Madame D'Arbly's *Diary*, L. R. Seelye's *Mrs Thrale* (1891), and Broadley's *Dr Johnson and Mrs Thrale* (1910), with introductory essay by Thomas Seecombe, and Mrs Thrale's unpublished journal of the Welsh tour in 1774.

Pip is the name by which various diseases in fowls and pheasants were once known. Roup (q.v.) is now the term in use.

Pipa, a genus of Amphibia (q.v.), of which the best known is the Surinam Toad.

Pipal. See PEEPUL.

Pipe, a measure of quantity which has been employed in Portugal, Spain, France, England, and in some other countries, used almost exclusively for wine and oil. In England it is also called a butt, and is equal to two hogsheads. But the capacity varies with the locality as well as with the description of wine the cask contains: a pipe of port is 137 imperial gallons; of sherry, 130 imperial gallons; that of Madeira, 110 imperial gallons; while the common English pipe contains 126 wine gallons, or nearly 105 imperial gallons.

Pipeclay, a fine white plastic clay, very like kaolin, but containing a larger percentage of silica. For the manufacture of tobacco-pipes the most desirable clay contains only small traces of limonite and alkaline earths. Clays of this nature are met with in Cornwall, Devon, and Dorset, but the purer varieties of clay used for pottery-making are also employed in the manufacture. Such clays, however, have siliceous materials added to them artificially. Pipeclay is used by soldiers for whitening belts, &c.

Pipe-fish, a family of remarkable fishes in the same (Lophobranch) order as the Sea-horses. The body is elongated like a thin pipe; the jaws are prolonged in a tubular toothless snout; the muscular development is slight; the skin is covered with an armature of hard plates; the gills are in the form of tufts, and the branchial aperture is very small. The eggs are carried about and hatched by the male, usually within a capacious pouch formed from two folds of skin on the ventral surface of the tail-region. One of the commonest British species is the Great Pipe-fish (*Syngnathus acus*), which is sometimes found in deep water, and sometimes at low tide among the seaweed in rock-pools. The specimens commonly seen are from 1 foot to 18 inches in length. It may be seen slowly moving

about, with curious contortions, poking its long snout into every crevice in search of food, and sometimes assuming a vertical position with the head downwards, boring into or stirring the sand.

Pipe-fish (*Syngnathus acus*).

One of the commonest American pipe-fish is *Siphonostomus pecki*, which lives among the eel-grasses of the coast.

The name Pipe-fish is sometimes given also to the fishes forming the family *Fistulariidae*, or Flute-mouths, of which one of the most remarkable is the Tobacco-pipe-fish (*Fistularia tabaccaria*). But these are large marine sticklebacks, and have only a superficial resemblance to the true pipe-fish.

Piperaceæ, a family of dicotyledons, natives almost exclusively of the hottest parts of the globe, particularly of Asia and America. About 1200 species are known, to most of which the name Pepper (q.v.) is sometimes given, although some are also known by other names, particularly those of which the fruit is not used as a spice, but of which some part is employed for some other purpose, as Betel, Cubebs, Matico, and Ava.

Piperine, an Alkaloid (q.v.) found in pepper.

Pipe-rolls. See RECORDS.

Pipes of ductile metal, such as brass, copper, and tin, are made by first casting an ingot into the shape of a lead-pencil, with a hole through its length of the same diameter as the bore of the pipe is intended to have. Into this is placed an iron rod, called the mandrel, which exactly fits, and projects slightly at the tapered end, which is then put into a funnel-shaped hole drilled through a steel post, and gripped on the other side; the machine power is then applied, and the soft metal and its mandrel are drawn through, the former being extended equally over the surface of the latter, which is then removed, and the length of pipe is complete. Some metals require repeated drawing through smaller and smaller holes, and have to be softened or annealed at intervals, as the metal hardens under repeated drawing. In this way brass, copper, tin, and pewter pipes are made; but lead pipes are made of great lengths by squeezing the soft metal through a hole in a steel plate in which there is a fixed core or mandrel projecting, which forms and regulates the size of the bore of the pipe. Pipes are also made from copper, brass, and malleable iron by rolling out narrow strips of metal, and then passing them successively through rollers, which are deeply grooved, and which turn up the edges. A mandrel is then laid in it, and it is next passed through double-grooved rollers, which turn the edges in, and thus form a complete tube round the mandrel. The edges, however, require hard soldering—i.e. soldering with a fusible brass alloy, or welding, if of iron. All boiler-tubes used to be made in this way; but the method of drawing has been so much improved that copper and brass pipes, or tubes, as they are frequently called, are now drawn of considerable thickness and diameter. Steel tubes likewise are drawn. Iron pipes, as for water and

gas, are cast. Steel water-pipes can be made by rolling, the edges being riveted and caulked. See WATER-SUPPLY. For earthenware pipes see POTTERY, DRAINAGE, SEWAGE. See also for various kinds of pipe, TOBACCO, FIRE.

Pipi, the name given to the ripe pods of *Cassia-pipia Papai* (see CASSALPINTIA), which are used in tanning, and are not infrequently imported along with Dividivi (q.v.).

Piping Crow, and PIPING CROW SHRIKE, are names sometimes loosely applied in Australia to any bird of the genus *Gymnorhina* or *Barita* (q.v.); now more commonly known as 'Magpies.'

Pipit (*Anthus*), a genus of small birds forming with the wagtails the family Motacillidae. The pipits have a strong resemblance to the larks in external appearance, and even in many of their habits, such as singing while on the wing; but they moult twice a year, while larks moult only once. With the wagtails they agree in all respects except in colour, and like them they are chiefly terrestrial in habit, running along the ground, working in and out among grass or heather in search of the insects, worms and slugs which

Meadow s-pipit (*Anthus pratensis*).

form their food. The Meadow-pipit (*A. pratensis*), also known as the Titlark or Moss-cheeper, is the species most abundant in Britain. It breeds early in spring, nesting in a hollow on the ground or under a bank, and rears two broods in a season. The Tree-pipit (*A. trivialis*), though only a summer visitor, is common in many districts, and breeds freely in the south and west of Scotland. The Rock-pipit (*A. obscurus*) frequents rocky shores and feeds on molluscs and small crustaceans.

Pippi. See GIULIO ROMANO.

Pippin. See PEPIN.

Pippin, a name given to many varieties of apple, among which are some of the finest in cultivation, as the *Golden Pippin*, *Ribston Pippin*, &c.

Piprahwa, or PIPRAWA, a village of India, near the frontier of Nepal, in the Basbi district of the United Provinces. Here is a ruined tope, which, following excavations by W. C. Peppé in 1896-98, proved to be one, and the first to be revealed in modern times, of the topes erected over the distributed ashes of the Buddha (see BUDDHISM). The tope itself, the underlying stone coffin holding the ashes, and various objects contained in the coffin, among them a vase bearing an inscription, are of first importance in the evidence they offer as to the state of civilisation in India about 450 B.C. See Peppé's article in the *Journal of the Royal Asiatic Society* (1898).

Piqua, a city of Ohio, on the Miami River (here crossed by two bridges) and canal, 28 miles by rail N. of Dayton. It has foundries and factories for woollens, worsteds, oil-mill machinery, flour, furniture, &c. Pop. (1890) 9090; (1920) 15,044.

Piquet, a game at cards for two players, played with thirty-two cards, the sixes, fives, fours, threes, and twos being rejected. The game was formerly played a hundred up, a *partie* being the best of five games; but about 1880 the rubicon game superseded piquet *au cent*. At the rubicon game six hands are played, each player dealing alternately. The one whose aggregate score is the higher wins the *partie*. He deducts the loser's score, and adds a hundred to the difference. If the loser fails to score a hundred in the six hands, he is *rubiconed*, and the scores are added instead of being deducted. For a description of the mode of play, handbooks should be consulted.

The earliest known mention of piquet is by Rabelais in the Gargantuan list of games (1530-45). Hence it has been concluded that piquet is of French origin. But it is more probable that a similar game, called *rouffa*, was played in Italy at an earlier date, and that this game, with modifications, travelled from Italy to Spain, where it was renamed *centos*, and to France, where it was renamed *piquet*, a word of which the etymology continues unsettled. In England from the time of the marriage of Mary to Philip of Spain (1554) the English equivalent (*cent*) of the Spanish name of the game was in vogue, and contemporaneously with the marriage of Charles I. to the daughter of Henry IV. of France (1625) the French name *piquet* would seem to have been substituted.

In 1651 was published *The Royal and Delightful Game of Piquet*, translated from the earliest known French book on the subject. The first important original work in English was Horace's *Short Treatise on the Game of Piquet* (1744). This included the laws which were the authority until 1873, when the Portland Club issued a code. The general adoption of the rubicon game, shortly afterwards, necessitated a fresh revision; and in 1881 the Portland and Turf Clubs agreed to the code of laws which now governs the game. These laws were published in 1882, together with a history of and a treatise on the game, by 'Cavendish'; there have been various later editions.

Piracy (Lat. *pirata*; Gr. *peiratēs*, 'an adventurer', 'a pirate'), robbery on the high sea, was apparently very much mixed up with early maritime adventure, the sea-rover being frequently pirate as much as trader; thus, the Phœnicians often combined piracy with more legitimate seafaring enterprise. In Homeric times piracy was accounted a reputable or even dignified calling; and the Greeks, especially the Phœnicians, long displayed a natural genius for piracy. This aptitude was cherished by the constant warfare between small states, it being difficult sometimes to decide what was public and what was private war. Cicia was long the headquarters of Mediterranean piracy, until in 67 B.C. Pompey made his memorable expedition against the pirates with great naval and military forces. From the 8th to the 11th century the Norse vikings were the terror of western coasts and waters (see NORTHMEN). The Hanseatic League (q.v.) had its origin in the desire for mutual defence against Baltic and other pirates. At a later date the Moslem rovers scourged the Mediterranean, commingling naval war on the large scale with peddling, thievery, and the abduction of slaves; Algiers was a piratical stronghold till well into the 19th century (see COUSAIRS); and in the 17th century the English Channel swarmed with Algerine pirates. The Buccaneers (q.v.) preyed mainly on the Spanish commerce with the Spanish American colonies. Lundy Island (q.v.) was long a nest of pirates, English and other. Captain Kidd (q.v.) is in the popular mind the chief representative of the picturesque type of pirates, whose career of reckless blood-

shed and rapine under their 'Jolly Roger' or black flag, alternating with luxurious debauchery, has come to be surrounded with a halo of romance, reflected in E. A. Poe's *Gold Bug* and R. L. Stevenson's *Treasure Island*. The prototype of Scott's *Pirate* was John Gow, who in January 1725 boldly anchored in Orreidian waters, and entered into friendly relations with the islanders, till, recognised as an atrocious villain, he was with his crew captured and carried to London to be tried. He and eleven of his comrades were condemned a month or two after, and the pirate captain and nine of his men were executed together. So late as 1864 five men were hanged in London for murder and piracy. National prejudices tend to obscure the distinction between privateering (see *PRIVATEER*) and piracy: Paul Jones (q.v.) was called a pirate in England, and the commanders of the Confederate ships *Alabama* (q.v.), *Shenandoah*, and *Florida*, which preyed on northern commerce, were in northern eyes practically pirates. Of late the pirates tried by admiralty courts are rather naval mutineers than pirates in the old sense. The African slave-trade was not considered piracy by the law of nations; but the municipal laws of the United Kingdom and of the United States by statute declared it to be so; and in or after 1841 it was declared to be so by Austria, Prussia, and Russia. The home of professional piracy, now on a small scale, is the Malay Archipelago and the China Seas; Sea-Dyaks and Malays disputing with Chinese the palm of hardihood as sea-robbers.

Piracy is recognised as an offence against the law of nations. It is a crime not against any particular state, but against all mankind, and may be punished in the competent tribunal of any country where the offender may be found, or into which he may be carried, although committed on board a foreign vessel on the high seas; but it is not permitted to put pirates to death without trial save in battle.

See H. A. Ormerod, *Piracy in the Ancient World* (1924); Philip Gosse, *The Pirates Who's Who* (1924), and his edition (vol. i. 1926) of Captain Charles Johnson's *A General History of the Pyrates* (1724), which treats of English pirates only. Johnson was possibly himself a pirate, and his work, the general historical accuracy of which has found support in modern research, is famous as the great inspiration of pirate stories.

Piræus (Gr. *Peiræus*), called also *PORT DRAGO*, the harbour of both ancient and modern Athens (q.v.). Planned by Themistocles and laid out by Hippodamus of Miletus, the Piræus was built in the glorious days of Pericles; this ruler and Cimon before him built the three 'long walls' that connected Athens with its port (5 miles to the south-west), and so ensured a free and safe passage from one to the other at all times. It was both a war harbour and a commercial port, many foreigners living within its walls. Its arsenal (built 347-323 B.C.) and fortifications were destroyed by Sulla in 86 B.C., and from that time the town sank into decay. The modern Piræus, which has grown up since 1834, is a regularly laid-out but mean-looking town, with a naval and a military school, arsenal depôts, and miscellaneous manufactures, and is growing rapidly. A railway (1869), 5½ miles long, connects it with Athens, and another with Athens, the Peloponnese, and the general European system. It is the principal port of Greece. Pop. (1871) 11,000; (1879) 21,055; (1890) 36,000; (1920) 133,482.

Pirandello, **LUIGI**, Italian novelist and playwright, born at Girgenti in 1867, is principally known by some striking plays (written mostly during or since the Great War), *Six Characters in Search of an Author*, *Henry IV.*, *Right You Are*

(if you think so), *Naked*, &c., in which largely he discusses, with an ironic style, the question of reality, identifying it in its usual meaning, with the conventional and the illusory, whereas the real life is that of ideas, evolved from the subconscious. Pirandello gives an objective reality to his own fictitious characters, besides somewhat exaggerating them, so as to throw the substance of life into higher relief.

Piranesi, **GIOVANNI BATTISTA**, Italian engraver, 'the Rembrandt of architecture,' was born 4th October 1720 at Venice. He studied art there and at Rome, and worked for a time as an architect. Of his engravings, of which he left about 2000 (29 vols., Paris, 1835-36), the best are of the architectural ruins of ancient Rome. In his work he restored the missing parts of ruins and introduced statues, tombs, vases, altars, and other details. Latterly he was assisted by his family, chiefly his son Francesco, and his daughter Laura. He died at Rome or at Tivoli 9th November 1778. See A. Samuel, *Piranesi* (1910; 2d edition 1912).

Pirano, a seaport of Italy, on a promontory on the south side of the Gulf of Trieste and 12 miles SW. of the city of Trieste. It has two harbours, picturesque Venetian walls (14th century), some interesting buildings, and manufactures of soap, glass, &c., with neighbouring salt-works. It was the birthplace of the violinist Tartini. Pop. 14,000.

Pirates. See *PIRACY*.

Pirkheimer. See *DÜRER*.

Pirmasens, a town of the Bavarian Palatinate, and formerly the chief town of the county of Hanau-Lichtenberg, 34 miles by rail W. of Landau. The chief manufacture is shoes. Close by the Prussians under the Duke of Brunswick defeated the French commanded by Moreaux on 14th September 1793. Pop. (1885) 14,938; (1895) 24,548; (1925) 42,906.

Pirna, a town of Saxony, stands on the left bank of the Elbe, 11 miles by rail SE. of Dresden. Here are a fine 16th-century church; a castle (1573), used as a lunatic asylum since 1811; and manufactures of glass, chemicals, tobacco, stoves, &c. Sandstone-quarrying, once important, has declined, as the stone decays where there is coal smoke. Pop. 20,000.

Pirogue. See *PERIAGUA*.

Pirot, an industrial town of Serbia, on the Nishava, 30 miles ESE. of Nish, noted for its manufacture of carpets. It is of strategic importance, was occupied by Serbian troops in 1877, and taken by the Bulgarians in 1885 and in 1915. Pop. 11,000.

Pisa, a city and archiepiscopal see of Italy, once the rival of Venice and Genoa, which still has its walls standing and a citadel, is situated on the Arno, by rail 49 miles W. of Florence and 13 NE. of Leghorn. It was formerly a great port, though six miles from the sea, but owing to the silting-up of the river is now quite inaccessible to ships. Its commerce has been transferred to Leghorn. It is still a city of fine buildings, foremost amongst which is the cathedral (1063-1118), with a noble dome, fine paintings and mosaics by Cimabue, Andrea del Sarto, and others, and beautiful marble altars. Its shape is that of a Latin cross, 311 feet long by 252 wide; the nave is 109 feet high. Externally it has a magnificent façade of four superimposed rows of pilasters and arches, and fine bronze doors by Giovanni da Bobogna and others. Near the cathedral stands the round marble campanile, the 'Leaning Tower of Pisa,' which is a magnificent specimen of the southern Romanesque architecture, but it is peculiar in that it (including the cornice) deviates about 14 feet

from the perpendicular. This peculiarity is not due to original design. The tower seems to have begun to heel over to one side when the third story was completed; the architects deliberately accepted the conditions, and adhered to the inclining position, but diminished the slope of the upper stories so as to keep the centre of gravity well within the walls. (There are two leaning towers also at Bologna, q.v.) The tower is 180 feet in height, consists of eight stories divided by rows of columns, the last, which contains the bells, being smaller in diameter than the others. The tower was erected in 1174 and succeeding years by the architects Bonanno of Pisa and William of Innsbruck; but the eighth story was not completed till the middle of the 14th century. The marble Baptistery, or Church of St John (1152-1278), opposite the cathedral, is circular, and supports a dome, crowned with a cupola. The interior, noted for its wonderful echo, contains the grand and elaborate pulpit of Nicola Pisano (1260) and a large marble font. The beginning of the Campo Santo, or ancient national cemetery, was several loads of earth brought from Jerusalem towards 1200. In 1278-83 the ground was surrounded by cloisters by Giovanni Pisano, the walls of which were adorned with fresco-paintings by Orcagna, Benozzo Gozzoli, and others. The city contains

Leaning Tower and Cathedral, Pisa.

numerous other churches, some dating from the 11th century; also many fine palaces, private and official residences, including that of the archbishop. The university (1338) has a natural history museum, a botanical garden, and a library (1742). The town possesses a museum of fine arts and archives. Amongst distinguished natives of Pisa may be named the popes Eugenius III. and Nicholas V., the Visconti, Peter the Deacon, Leonardo the mathematician, Giovanni (but not Nicola) Pisano, and Galilei. The industrial activity is now confined to cottons, silks, ribbons, and the working of coral and alabaster. Dromedaries are bred at the royal farm of S. Rossore in the neighbourhood. Pop. of commune (1881) 53,957; (1921) 67,752.

The province has an area of 1180 sq. m. and (1921) a pop. of 359,368.

History.—Ancient Pisa, originally an Etruscan city, became subject to Rome in the 2d century B.C.; but, on the decline of the western empire, it was compelled to submit in turn to the nations who successively overran Northern Italy. Early in the 11th century Pisa had developed into a powerful republic, possessing a formidable fleet and extensive territories along the Tyrrhenian Sea; it yielded little more than nominal homage to its suzerain lords, the German emperors. Throughout the 11th century Pisa was at the height of its prosperity; to this period belong most of the splendid monuments of art that still adorn the city. It had extensive commercial relations with the East; its 'customs of the sea' (1075) were the pattern upon which the sea-laws of nearly all peoples navigating the Mediterranean were modelled. During the same century the Pisans repulsed the Saracens (1011), took Sardinia from them in 1022, attacked them in Africa in 1030, and routed them utterly off Palermo in 1062. Early in the next century, in 1114-16, they wrested the Bulgaric Isles from the same enemies. In the second crusade too they played a prominent part, and helped the pope against the Normans, taking Anagni in 1135 and again in 1137. But already in the 11th century the rivalry between Pisa and Genoa had broken out. Florence too, a Guelph city, grew into an enemy of the Ghibelline Pisa. Wars many and often were waged between Pisa on the one side and a coalition of cities, headed by Florence and Genoa, on the other, with varying fortune, until in 1284 the Pisan fleet was crushed at Meloria. After this Pisa was compelled to give up Corsica, part of Sardinia, and 160,000 gold pieces to Genoa. At the same time Ugolino (q.v.) della Gherardesca made himself master of the town. Various individual rulers or tyrants followed, until the Pisans finally threw themselves (1399) under the protection of Galeazzo Visconti of Milan. The son of the latter sold the Pisan territory to their greatest enemies, the Florentines, from whose tyrannical rule they were for a time relieved by Charles VIII. of France, who, in 1494, accepted the protectorate of the city. When the French left Italy the old struggle was renewed; and, after a desperate resistance, the Pisans, in 1509, were compelled by hunger to surrender to the Florentine army. The most influential families, as formerly in 1406, emigrated. From this time Pisa steadily declined, until in the middle of the 16th century it had less than 8600 inhabitants. Its history henceforth coincides with that of Tuscany (q.v.). With the rest of Tuscany it became part of the kingdom of Italy in 1860. See R. Papini, *Catalogo delle Cose d'Arte di Pisa* (1912).

THE COUNCIL OF PISA met in Pisa on 25th March 1409, and held its twenty-third and last session on 7th August. Its aim was to end the schism which had divided the Western Church for thirty years, and with this view the leading cardinals, finding that neither of the rival popes, Gregory XII. and Benedict XIII., would keep his promise to abdicate, set aside the claims of both, and themselves convoked a general council. After the rival popes failed to appear in obedience to its summons, the council formally tried the claims of both in turn, and deposed them as schismatics and heretics. The cardinals then formed themselves into conclave and elected Cardinal Philargi, who assumed the name of Alexander V. But the council, instead of getting rid of the contending popes, had only added a third, and the faithful continued to be distracted in their allegiance for eight years longer, down to the time of the Council of Constance. Bellarmine considers the

Council of Pisa as 'neither clearly approved nor clearly rejected'; 'Hefele says 'neither ecclesiastical authority nor the most trustworthy theologians have ever numbered it among the ecumenical councils.' See Hefele's *Conciliengeschichte*, vol. vi.

Pisan, CHRISTINE DE (1363-c. 1430), French poetess and religious and historical prose-writer, born in Venice went to France in 1368 with her father Thomas Pisan, Charles V.'s astrologer. Widow of Étienne Castel, she supported her family by literature.

Pisanello. See **PISANO (VITTORE)**.

Pisano, ANDREA, also known as **ANDREA DA PONTEREDERA** (1270-1348), was born at Pontedera, near Pisa, and was first a goldsmith, but became famous as a worker in bronze and a sculptor in marble. He is doubtfully stated to have been a pupil of Giovanni Pisano. He settled in Florence, and became the founder of the Florentine school of sculpture. His best work at Florence (one of the baptistery doors and many sculptures on the Campanile) shows strong traces of Giotto's influence. His sons Nino and Tommaso were also sculptors. See Perkins, *Tuscan Sculptors* (2 vols. 1864), and works on Italian sculpture and sculptors by Leader Scott (1882), Freeman (1901), Waters (1911).

Pisano, GIOVANNI (1250-1330), Italian sculptor and architect, was born probably at Pisa, the son and worthy successor of Nicola Pisano (q.v.). He designed the fine marble high altar and reredos in the cathedral of Arezzo and the little chapel of Sta. Maria della Spina at Pisa; executed pulpits in the church of St. Andrea at Pistoia and in the cathedral of Pisa; and worked with many pupils in the cathedral at Florence. The tomb of Pope Benedict XI. at Perugia, long attributed to him, possesses few of his characteristics. See works cited at **PISANO (ANDREA)**.

Pisano, NICCOLÒ (c. 1206-78), a distinguished sculptor of Pisa, was born apparently near Lucca. His earliest work is supposed to be the 'Deposition' over one of the doors of the cathedral at Lucca, dated 1237. His reputation is supported by three important works—the pulpit of the baptistery at Pisa (1260), the 'Arca' or shrine of St. Dominic for the church of that saint at Bologna (1267), and the pulpit of the cathedral at Siena (1268). He died at Pisa, and was buried in the Campo Santo. He was also a great architect and a skilful engineer. His influence was wide, reviving the love of beauty and giving new birth to the plastic arts. His pupils Arnolfo and Lapo executed numerous works at Rome, Siena, and other cities. See works cited at **PISANO (ANDREA)**.

Pisano, VITTORE, commonly called **PISANELLO** (c. 1380-1456), Italian medallist and painter, was born at San Vigilio, near the Lake of Garda. He revived the neglected art of the medallist, and was the first great Veronese artist, his work being best seen in his frescoes. He enjoyed great repute in his day. His paintings excelled in the treatment of animals, but few survive. To day he is best known by his medals. See G. F. Hill, *Pisanello* (1905).

Pisaurum. See **PESARO**.

Piscataqua, a river which constitutes part of the boundary between Maine and New Hampshire, and forms at its mouth the excellent harbour of Portsmouth. See **NEW HAMPSHIRE**.

Pisciculture. Some knowledge of the artificial propagation of fishes has been turned to practical account from the remotest periods of history, but the records are such that though it is evident the Egyptians and Hebrews in the time of the Pharaohs, and later the Greeks and Romans, practised fish-culture, we do not know to what extent. It is probable that their knowledge was

confined to certain means of protection and control, which enabled them to take advantage of the natural reproduction and growth of certain food fishes. The Chinese, too, have had, possibly for thousands of years, a knowledge of fish-culture, but here again we find that their work begins after the ova have been deposited in a natural manner.

It is to modern fish-culture we must look for a thorough and scientific development, and it must be confessed that though much has been accomplished there is room for wide research. Something more than a foundation has been laid, and results of great national and individual importance have been achieved.

It is obvious that pisciculture, as practised by ancient peoples and later by the inmates of religious institutions in this country, based on control and protection of fish rather than their propagation, was far from being all that could be done; so it is not surprising to find that in the 15th century a monk, Dom Pinchon, experimented with the artificial fertilisation of fish-eggs. But it is surprising that it is not till three centuries later we hear any more of this extended pisciculture. Between 1725 and 1765 Stephan Ludwig Jacobi, a native of Lippe-Detmold, successfully bred trout artificially. Again a century elapsed before this was turned to practical account, and it is not till 1842 that we find Rény, a French peasant fisherman, making use of the artificial propagation of fish for commercial purposes. He, with a partner of the name of Gélmin, set to work to increase the number of fish in the streams of his native district. Their efforts met with success, and from that time fish-culture has grown in importance all over Europe.

In this country Frank Buckland published his book *Fish Hatching* in 1863, and by then the value of pisciculture was so well realised that he wrote that it promised 'to be eventually the origin of increase of revenue to private individuals, a source of national wealth, and certainly a great boon to the public in general.' It may be said now that this prediction has on the whole been fulfilled, for we find rivers and lakes constantly restocked with artificially-bred trout, to replace the toll taken by anglers and fishermen; the value of fishings has increased, and this, so far as trout are concerned, is largely due to the fact that the yield and quality of fish can be controlled. Nevertheless the present state of affairs falls far short of Frank Buckland's vision, and this is due to statutory limitations which have prevented the Fishery Boards for England and Scotland, and, later, their successor the Board of Agriculture and Fisheries, from taking the active part in fishery development that the United States Fishery Commission and several Continental governments have done. So far as fish-culture is concerned, development and progress have been left almost entirely in the hands of private individuals working along commercial lines, and consequently compelled to follow rather the most profitable branches than those which would have been of national importance. This has resulted in a number of highly developed and efficient trout-farms, and an absence of salmon-hatcheries and rearing-stations on anything like an adequate scale; the reason being, of course, the limited range and complete control possible in the case of trout; and the anadromous habits and wide range of the salmon which make individual enterprise unattractive. It is not to be inferred that our Fishery Boards and Board of Agriculture and Fisheries have done no good work. This is far from being the case, but one feels that the research work and investigation into the life and habits of the salmon should be carried a step further, and

the knowledge acquired turned to practical account. In this connection it may be said that the greatest advance in knowledge in recent years is due to the discovery that the life-history of a fish is outlined and its age recorded by the ring-markings on its scales. Our knowledge of the life-histories of the migratory salmonidae particularly has been extended by this means.

Marine fish-culture is carried on experimentally by the Board of Agriculture and Fisheries at several seaside biological stations, and enthusiastic investigators have, as in the case of the salmon, knowledge which would enable them to develop and improve our sea-fisheries, but up to the present government has only seen its way to use this for administrative purposes; and it must be admitted that international complications are at present an inseparable difficulty in any scheme of practical marine fish-culture.

Turning now to inland fisheries, we may consider in detail the branch of fish-culture which has been most successful, owing largely to private enterprise and a more or less fallacious idea that fish-culture could be made profitable to the private fish-culturist. Large sums of money have been sunk in piscicultural establishments. Sir James Maitland at Howietoun, Stirling; J. J. Armistead at the Solway Fisheries, Dumfries; Thomas Andrews at Guildford, Thomas Ford at Caistor, Colonel Custance at Norwich, may be mentioned as pioneers of what may be called commercial pisciculture, though in none of these instances has the financial return been equal to the cost of years of experiment and research.

Trout are reared at various establishments in this country almost exclusively for the restocking of private waters for angling purposes. Of late years some of the trout-farms have been producing directly for the food-market. It is not yet clear whether this can be made to pay when the fish are entirely hand-fed, though there is no doubt whatever that it would be profitable if natural feeding were supplemented by hand-feeding.

A trout-farm consists of a hatchery and a set of ponds for breeders and for rearing purposes. In some cases the output may be a hundred thousand eggs or so, and ten to twenty thousand yearlings; in others, several million eggs and several hundred thousand yearlings.

The restocking of trout waters is accomplished either by the planting of incubated eggs in specially prepared beds, the liberation of fry a few weeks old, the turning down of yearlings or two-year-olds, and, in some cases, three-year-olds.

For many years the difficulties of successful transport of live trout hindered the development of this useful branch of fish-culture, as a large volume of water, necessitating heavy tanks and incidentally heavy freight charges, was required; and in the early days it was invariably the custom to send an attendant to change the water *en route*, and look after the fish generally. Greater knowledge of how to prepare the fish for a journey, the value of low temperature and the use of ice, and latterly the use of oxygen, have overcome the earlier difficulties, so that to day small trout undertake long journeys without serious risk in a quarter of the volume of water required for short journeys at the end of last century. In this way young trout have been distributed over Great Britain and Ireland, and many hard-fished waters depend upon an annual replenishment from some piscicultural establishment. In 1901 the writer succeeded in sending a small consignment of American trout-fry (*Salmo fontinalis*) to Natal without appreciable loss or the changing of water *en route*. Probably the most important work accomplished by fish-culturists in this country up to the present

time is the distribution of trout and salmon eggs to every part of the world where the climatic conditions made this worth while. This work was begun as early as the middle of last century, and some of the first consignments to the antipodes were by sailing-ship. Later, when steamers were made use of and the advantages of cold storage were understood, it became a comparatively easy matter to send large quantities of eggs to any part of the world. The last large consignment of salmon-eggs from this country was in 1910, when more than a million were despatched to New Zealand. These arrived in good condition, and were successfully hatched off in the New Zealand Acclimatisation Society's hatcheries, and distributed to various rivers, in some of which they became established.

In this country the varying capacity of lake and stream to support trout life was not sufficiently realised in the early days. Lightly-stocked waters, which were in reality stocked to their full capacity, were expected to maintain as many fish as waters naturally rich in the necessary food supplies. In some cases this led to disaster, and the original stock of trout were faced with partial starvation, owing to the too urgent methods of the fish-culturist, who at that time worked solely to increase the number of fish per acre without having any regard to the food supply. The many instances where increased stocks did well retarded the realisation of the need for care.

The fish culture of the future must concern itself mainly with this important matter of food production. Hatching and rearing trout are comparatively simple matters. Needless to say, the function of the fish-farm is invaluable when it comes to replenishing stocks of trout in overfished waters that are rich in food.

The most important lesson that pisciculturists have learned since Frank Buckland's day is that success must be built on a broad and deep knowledge of aquaculture. This discovery was a costly one. It means that the useful functions of the trout-farm are limited to favourable natural conditions and the replenishing of depleted stocks. Except in rare instances pisciculture is a long way from its original ideal expressed by the analogy of making two blades of grass grow where only one grew before.

With this knowledge gained, the pisciculturist has come to realise that natural methods were not so wasteful and unreliable as he had supposed, but that they were all along producing the stock that could be carried. He knows now that as the agriculturist must prepare the land to bear the desired crops, so must he prepare the water, or be content with what nature provides.

Briefly, it may be said that pisciculture as understood in the middle of last century has been successful to a limited extent only; and the interval has been occupied in discovering its limitations, and how to extend its usefulness.

If the assertions of Frank Buckland's day are no longer heard, there is nevertheless a deep assurance that, though others may reap where the pioneers have sown, pisciculture is worth while, and will eventually take a recognised place alongside its much older sister—agriculture.

In conclusion, a short account of the methods adopted on a trout-farm may prove of interest, showing, as they do, that the artificial side of pisciculture has been developed to a pitch of high efficiency.

From a pond where breeders have been stored, the trout are taken during October, and the early spawners are retained in a smaller pond till they are ripe; the later fish are returned to their pond to await the next overhauling, which will take place

in a fortnight or three weeks. Care is taken to give the fish that are held up plenty of room, the old method of keeping them in tanks till ready has been discarded, as it was found that this lowered the vitality of the parent fish and adversely affected the vitality of the eggs. Plenty of room and plenty of running water are essentials for healthy spawners. The fish are handled as little as possible. After the first overhauling a skilled man can tell when he may expect the first eggs. He keeps an eye on the thermometer, knowing that cold weather will delay spawning operations, while mild weather and rain will hasten them.

When a number of fish are ripe, preparations are at once made for taking the eggs. The operator stands before a table on which are a number of clean basins. With a towel he carefully dries one of these, and an assistant hands up a female fish in a net. This the operator takes in such a way that it lies with its tail in his left hand and its head in his right, belly upwards. Then holding it over the basin, and with tail depressed and head raised, he gently slides the right hand over the abdomen, holding the fish to him with wrist and arm. A very gentle pressure is all that is needed. The eggs flow in an even stream from the vent into the basin, and the passing of the right hand over the abdomen three times should be enough to expel the last egg. The fish is then laid in a tank through which passes a stream of clean water. Four or five females are treated in the same way, and then a male is taken. The method of extracting the milt is much the same as in the case of the eggs, only, instead of the hand, the first finger and thumb are used to give pressure over the lower part of the abdomen. The milt is then carefully mixed with the eggs, and perhaps another male used. A cup full of clean water is added, and the eggs gently stirred, then the basin is slowly filled with water, and placed overhead in a tank with a gentle current. This clears away the cloudy milt and any urine from amongst the eggs, and they are left for half-an-hour or so while they absorb water and swell. During this time they adhere to the basin and to each other, and they must not be disturbed. When they separate they are removed to the hatchery. Here they are laid in hatching-boxes, which are simply shallow troughs of wood or slate or concrete, of such a size as may be considered convenient, this being unimportant so far as the eggs are concerned. A gentle even current is necessary, and a depth of from four to nine inches. Too shallow a tank gives either a poor current, or one which will move the eggs about; too great a depth is inconvenient. In actual practice two to three inches of water over the eggs has been found convenient, and the same depth below the trays on which they are laid. At first gravel was used in hatching-tanks, but it was found that this was not necessary, and, besides, it collected sediment, and made it difficult to find and remove dead eggs—a most important item in the care bestowed during incubation, as one dead egg, if left, is capable of causing the loss of many. Various kinds of trays were tried, and it was found that in waters free from plumbosolvent properties, perforated zinc, or fine wire mesh, could be used. The ideal hatching-tray, and one which is in use in most establishments in this country, is made of glass tubes. The eggs lie between these in rows, and are surrounded by a gentle current.

The time taken in incubation of the ova varies from fifty to a hundred and twenty days according to the temperature. In water which has an approximate mean temperature of 40° F. hatching will take place in about ninety days. A long frost will extend the period. Spring water is often

much warmer, and when this is used the development of the embryo is more rapid.

(Ova that are to be despatched abroad are packed so soon as the embryo can be seen through the semi-transparent shell, and before the dark eye-spots are visible. This is usually about the end of a third of the incubation period. Before hatching, the eyes of the embryo become clearly defined as two black specks. When emerging from the shell the embryo usually shows its tail first, and it is a common sight to see one swimming about with the shell over its head for several hours before it can get rid of it. Frequently, however, the embryo emerges head first, and the writer has observed this more often with eggs from wild parents, while in the case of domesticated parents the progeny usually hatch off tail first.

For some weeks the little fish, known as an alevin, is encumbered with a yolk sac, which impedes its movement, but furnishes it with all the nourishment it requires. During this time the alevin is a very helpless creature, falling an easy prey to predatory birds, fishes, &c. Month and jaws are not fully developed till the yolk sac is absorbed, nor has it the full use of its fins. Under natural conditions it lies hidden in gravel till it is ready to come out and hunt for food.

It is not at all unusual successfully to bring 98 per cent. of the alevins hatched to the fry or feeding stage, and as the loss in incubation should not be more than 1 or 2 per cent., and is very often nil, it will be realised that to this stage the gain over natural methods in the rough and tumble of mountain streams, and amongst predatory creatures, must be considerable; and it was upon this fact that the pioneer fish-culturists built their hopes, only, there is no doubt, they over-estimated the loss under natural conditions.

It is at the fry stage that the pisciculturist's troubles begin. He has to find a suitable food for a great crowd of young fish which normally would be feeding on minute crustacea. For many years heavy loss occurred during the process of acclimating the digestive organs of the small trout to such food as could be provided. This usually took the form of finely-grated pig's or calf's liver. To-day more suitable foods are used, but liver is still the main stand by. Finely grated fish, ground boiled cockles, ground shrimps, &c., help to keep the fry healthy, so that instead of the 20 to 30 per cent. of survivors at a year old, which used to be an average achievement, 80 per cent. is common to-day, and 90 per cent. not unknown.

During the first year the young fish are subject to many parasitic and inflammatory diseases. These used to occur in epidemic form, but are now amenable to known treatment.

At an early stage the young fish have been removed to ponds where a current regulated to the right strength is provided. They have been hand-fed several times a day. The ponds have been kept free from decaying matter of any kind, whether dead fish or excrement. They have been sorted at least twice before they are twelve months old, and the large well-grown fish removed to ponds prepared for them, so that the smaller fish may not be bullied and starved, or even eaten. Constant care and watchfulness have been necessary all the time.

At a year old a hand-fed trout may be anything from 2½ to 10 inches in length. This extraordinary variation does not occur on one trout-farm, but represents the difference between fish reared in cold north-country water and fish reared in the warmer spring water of the chalk-stream counties. The potential growth of the two extremes under a given set of conditions is about the same: that is to say, 2½-inch fish from the north and 10-inch

fish from the south turned into, say, a Yorkshire reservoir will, at or before maturity, resemble each other in size. Both are governed by the conditions of the same environment, and these, so far as growth is concerned, are the determining factor. Normal sizes for north and south country yearlings are from 3 to 5 inches and 5 to 7 inches respectively.

Up to the beginning of this century most of the stocking in this country was done by means of yearling trout. Nowadays two-year-olds are favoured. This change is due mainly to improved methods of transport. Formerly the freight on the great cans used for the transport of two-year-olds was prohibitive.

From the very early days it was realised that our native Brown Trout (*Salmo fario*) is a very delicate fish, subject to epidemics and parasites, and that it is a capricious feeder. Therefore it is not astonishing that hardier species were imported from America, and of these the American Brook Trout (*Salmo fontinalis*), which is really a char, and the Rainbow Trout from the Pacific slope, promised great things. Compared with our own trout, they were much easier to rear, much less susceptible to various ills, and they were voracious feeders and rapid growers. Small wonder that fish-culturists were delighted. But, alas! these aliens had fatal characteristics which condemned them. Not the least disconcerting of these was their inevitable disappearance from any water they were turned into if it afforded access to the sea. Where they were successfully prevented from escaping they became unsatisfactory after a short but brilliantly spectacular career. They ceased to be surface-feeders, and they developed marked cannibalistic habits; and as they were such persistent foragers, they usually grew to at least twice the size of the indigenous trout. After enjoying a short boom they became unpopular, and, though a few are still reared, most of these go to the dead fish-market, and eventually figure in restaurants under such fantastic names as Blue Trout, &c. In Germany the Rainbow Trout, by reason of its rapid growth and the higher prices obtainable for food-fish, is largely cultivated, but even there it is a failure for stocking purposes.

Piscina (named from the swimming-pond in the old Roman baths), in Catholic churches a shallow stone basin with a drain usually leading directly to the earth, in which the priest washes his hands, and rinses the chalice at the end of the celebration of mass. In England it is almost invariably placed on the south side of the choir, at a convenient height.

Piscina.

Pisek, a walled town of Bohemia, stands on the Wottawa, an affluent of the Moldau, 54 miles S. by W. of Prague, and has iron and brass works, and manufactures of paper, boots, hats, cloth, &c. Pop. 16,000.

Pisgah, a name that seems to have applied generally to the mountain-range or district to the east of the Lower Jordan, identical with, or itself a part of, the mountains of Abarim (Dent. xxxii. 49; xxxiv. 1), one of the summits of which is Mount

Nebo (the modern *Neba*), 2644 feet above the level of the Mediterranean. From this point Moses enjoyed his glimpse of the Promised Land, in early spring. Though not the highest point, it is the nearest ridge to the Israelite camp in the plain of Shittim. The view to the east is shut in by the shelving edge of the Moabite plateau, and to the south is closed five miles off by a long ridge, but that to the west includes all the Judaean watershed, and in clear weather all Samaria and Lower Galilee, as far as Tabor and the chain of Gilboa. The Sea of Galilee and Hermon are shut out by the lofty range of Pennel (*Jebel Osha*) in Gilead, while the western watershed of Judaea and Samaria makes it impossible to see the waters of the Mediterranean; but below to the south-west the northern half of the Dead Sea is seen, bordered by the precipices of Engedi, beyond which stretches the dreary Jeshimon or desert of Judah. The burial-place of Moses is unknown, but may have been in the terrible gorge of the Zerka Ma'in, near or not far from the Callirhoe of the tyrant Herod's days.

See G. A. Smith, *Hist. Geog. of Holy Land*, pp. 562 ff.

Pishin, a subdivision of British Baluchistan, just north of Quetta, which has been governed by a political agent of the Governor-general of India since 1878. The British occupied it on account of its great strategical importance; it is the meeting-place of several roads, practicable for troops but not for wheeled carriages, leading from Sind and Punjab to Kandahar. The district—area, 3000 sq. m.; elevation 5000 feet—consists of alluvial valleys separated by ranges of hills, the whole sloping south-west, and surrounded by mountain-chains that reach in north and south 11,000 feet. The people, partly settled, partly nomad, grow wheat, barley, maize, millet, lucerne, water-melons, and musk-melons, and trade in horses to India. Pop. 50,000. A branch of the Indus valley railway traverses the principal valley.

Pisidia, one of the ancient divisions of Asia Minor, lay on the south, separated from the sea by the narrow strip of Pamphylia, and having Phrygia on the north, Isauria on the east, and Lycia on the south-west. Traversed by the main chain of the Taurus, it is a mountainous region, with an inhospitable climate. The people, a race of hardy and lawless mountaineers, were greatly given to predatory expeditions, and do not seem to have paid any regular obedience to the various oriental and other conquering races until Roman times. Under the Roman supremacy there were several prosperous cities, as Sagalassus, Antioch, Selge, Termessus. The boundaries of the province varied at different periods.

Pisistratus (Gr. *Peisistratos*), a famous 'tyrant' of Athens, was born about 600 B.C. At first he co-operated with his kinsman Solon. Early he acquired considerable military distinction. Afterwards he came forward as the leader of one of the three parties into which Athens was then divided—the *Dacrii* (party of the Highlands), chiefly a labouring population, jealous of the rich, and eager for equality of political privileges. Driving into the market-place of Athens and exhibiting certain self-inflicted wounds, he called upon the people to protect him against his and their enemies; thereupon, notwithstanding the strenuous opposition of Solon, he was allowed a bodyguard of fifty men, which he gradually increased, and in 560 B.C., seemingly with the tacit sanction of the citizens in general, seized the Acropolis. The heads of the rich aristocratic party fled, but returned in 554 and drove Pisistratus into exile, from which, however, he returned

by invitation, but was again expelled about 550. Supported by Thebes and Argos, he was able in 541 to sail with a strong force, landed in Attica at Marathon, and marched on the capital. His partisans hurried to swell his ranks. At Pallene he completely defeated his opponents, but used his victory with admirable moderation. Entering the city he resumed the sovereignty at once, and thenceforward lived in undisturbed possession of power, dying 527 B.C., and transmitting his supremacy to his sons, Hippias and Hipparchus, known as the *Pisistratidae*. Once he had resolutely established his authority his rule became of a kind that has won him the praise and esteem of all later ages. He firmly, but not harshly, enforced obedience to the laws of Solon; emptied the city of its poorest citizens, and made them agriculturists, supplying such as had no resources with cattle and seed; secured provision for old and disabled soldiers; bestowed great care on the celebration of religious festivals; encouraged literature more than any Athenian had ever done before—it is to Pisistratus, there is strong reason to believe, or to the poets, scholars, and priests about him, that we owe, for example, the first complete edition of Homer; and adorned Athens with many of its most beautiful buildings, such as the Lyceum, temples to the Pythian Apollo and the Olympian Zeus, &c. See works on Pisistratus by Flach (1885) and Topffer (1886); and Newball, *Pisistratus and His Edition of Homer* (Boston, 1908).

Pisolite (Gr. 'pea-stone'), a concretionary limestone, differing from Oolite (q.v.) in having the particles as large as peas.

Pissarro, CAMILLE (1831-1903), French impressionist painter of Spanish-Jewish descent, was born at St Thomas, Virgin Islands. He came to Europe in childhood, studied with the Danish painter Melbye, was influenced successively by Corot, Millet, and Monet, and lived near Gisors. Whether depicting the country or the boulevards of Paris he is always the painter of sunshine.—His son LUCIEN, born in Paris in 1863, lived in England from 1891, and became known as an engraver and a painter of English landscape.

Pistacia, a genus of trees of the family Anacardiaceae, having diœcious flowers without petals, and a dry drupe with a bony stone. The *Pistacia* or *Pistachio* tree (*P. vera*) is a small tree of about 20 feet high, a native of Persia and Syria, but now cultivated in all parts of the south of Europe and north of Africa, and in many places naturalised. It has pinnate leaves, with about two pair of ovate leaflets, and an odd one, flowers in racemes, fruit ovate, and about the size of an olive. The stone or nut splits into two valves when ripe; the kernel, which is of a bright green colour, is very oleaginous, of a delicate flavour, and in its properties very much resembles the sweet almond. In the south of Europe and in the East *Pistachio* nuts are much esteemed; but as they very readily become rancid they are little exported to other countries. They are sometimes called *Green Almonds*. Oil is expressed from them for culinary and other uses. In cultivation one male tree is allowed to five or six female ones. The tree produces flowers and even fruit readily enough in the south of England, but the summers are not warm enough to ripen the fruit, and the tree is apt to be destroyed by a severe frost. The Mastic-tree or Lentisk (*P. Lentiscus*), yields the gum-resin called Mastic (q.v.). It is a native of the countries around the Mediterranean. The Turpentine-tree (*P. Terbinthus*) yields the Turpentine (q.v.) known in commerce as *Cyprus Turpentine*, *Chian Turpentine*, or *Scio Turpentine*, which is of a consistency some-

what like that of honey, a greenish-yellow colour, an agreeable odour, and a mild taste, and in its properties resembles the turpentine of the Coniferae, but is free from acidity. The tree is about 30 or 35 feet in height, and has pinnate leaves, of about three pair of leaflets and an odd one, the flowers in compound racemes, the fruit nearly globular. The kernel of the fruit is oleaginous and pleasant. The Batoum Tree (*P. atlantica*), a round-headed tree about 40 feet in height, a native of the north of Africa, produces a fruit much used by the Arabs; and a gum-resin of pleasant aromatic smell and agreeable taste, which exudes from its stem and branches, is chewed to clean the teeth and impart a pleasant smell to the breath. The fragrant oil of the kernels of *P. oleosa*, a native of Cochin-China, is used there to perfume ointments.

Pistil, that part of the Flower (q.v.) which, after flowering, develops into the Fruit (q.v.).

Pistis Sophia. See GNOSTICISM.

Pistoia (anc. *Pistorium*), a town and episcopal see of Italy, stands 21 miles by rail N.W. of Florence, on a spur of the Apennines. Its streets are thoroughly Tuscan, and it is surrounded with walls, pierced by five gates, and has a citadel. The chief buildings are the cathedral of San Jacopo (12th and 13th centuries), containing a magnificent altar of silver (1286-1407) and several good sculptures; the church of St Bartholomew, with a fine white marble pulpit by Guido di Como (1250); St Andrea, with Giovanni Pisano's pulpit (1301); St Giovanni Fuorcivitas, with a font by Giovanni Pisano and terra-cottas by Luca della Robbia; the 14th-century communal palace and Palazzo Pretorio; the Ospedale del Ceppo, with terra-cottas by Giovanni della Robbia; and other palaces. The principal manufactures are iron and steel wares, agricultural implements, paper, oil, and silk. But the town has the credit of having invented and first made pistols, and of having given them its name in the form of *pistola*. Here Catiline was defeated in 62 B.C. The town was conquered by Florence and Lucca in 1306, and finally surrendered to the former in 1351. Pop. 70,000.

Pistol is the smallest description of Firearms (q.v.). See also REVOLVER.

Pistole, a gold coin formerly current in Spain and Italy, and originally equivalent to about eleven old French livres, though till about 1730 it was merely an irregular piece of gold. Its value varied somewhat at different times and in different countries, usually being between fifteen and sixteen shillings. The gold pistoles once current in the Welsh parts of Germany were in most cases merely convenient multiples of the ordinary thaler. The *Louis d'or* was intended to take in France the same place as the pistole in Spain.

Pita-hemp, one of the names of the Agave fibre. See FIBRIOUS SUBSTANCES.

Pitaka, 'basket,' is the title of each of the three subdivisions of the canon of the Theravādin school of Buddhism in Pāli (q.v.), the term Tripitaka thus standing for the whole canon. The subdivisions are *Vinaya*, 'discipline,' dealing with the rules of Buddhist monasticism; *Sutta*, dialogues in which the Buddha expounds the principles of his teaching; and *Abhidhamma*, comprising treatises of later origin, expounding a scholastic system of ethical psychology.

Pit and Gallows, a rendering of the grant of capital jurisdiction (*cum fossa et furca*) made to vassals by the crown in feudal times. Male felons were usually hanged on the gallows (*furca*); women drowned in a ditch or well (*fossa*). See BARON, DROWNING.

Pitavel, FRANÇOIS GAYOT DE (1673-1743), compiler of the famous collection of *Causés Célèbres* (see CAUSE CÉLÈBRE), served in the army, but became an advocate, and was known as an industrious and painstaking compiler. Of his great work there have been numerous abridgements, continuations, and translations; and his name has become so identified with the collecting of criminal cases that a similar work, published by various editors in Leipzig in 1843 and succeeding years, was called *Der Neue Pitaval* (2d ed. 36 vols. 1857-72; new series, 24 vols. 1866-90).

Pitcairn, ROBERT (1793-1855), editor of the invaluable collection, originally suggested by Sir Walter Scott, of *Criminal Trials in Scotland from 1488 to 1624* (3 vols. Bannatyne Club, 1833), held a post in the Register House at Edinburgh, where he was born and died.

Pitcairne, ARCHIBALD, physician and satirist, was born at Edinburgh, 25th December 1652. He graduated in arts at Edinburgh in 1671, and would seem to have been destined for the church, but subsequently read law at Edinburgh and at Paris, and finally adopted medicine as a profession, studying at Paris and becoming Doctor of Medicine of Reims in 1680 and of Aberdeen in 1699. He practised with success in Edinburgh till 1692, when the fame of his treatise on Harvey's discovery of the circulation of the blood secured him a call to Leyden as professor. There he remained only a year; his lectures being ultimately published as *Elementa Medicinæ Physico-Mathematicæ* (1718). He returned to Edinburgh to become one of the most famous physicians of his time; producing also *Dissertationes Medicæ* (1701), which contains his chief medical opinions. But he was even more famous, and notorious, as a Jacobite, an Episcopalian, a satirist of Presbyterian men and things, and, according to his opponents, as an atheist and scoffler at religion. *The Assembly* (1692, first printed in 1722) is a comedy in ridicule of the General Assembly of the kirk; and *Isabel* (1692, first printed in 1830) is a poem with the same aim. He was a good classical scholar, and his Latin verses, some of which were republished by Ruddiman in 1727, are creditable. He died at Edinburgh, 20th October 1713. There are editions of his medical works (Venice, 1733; Leyden, 1737), and in English from the Latin original (London, 1717), Webster's sketch of his life (Edinburgh, 1781) is on the medical side.

Pitcairn Island, a solitary island in the Pacific Ocean, between Australia and South America, in 25° 5' S. lat. and 130° 14' W. long., measures 2½ miles by 1 mile. It was discovered by Carteret in 1767, a midshipman Robert Pitcairn being the first to sight it, and was at that time uninhabited, although there were unmistakable evidences that it had been inhabited at one time. In 1790 it was taken possession of by nine of the mutineers of H.M.S. *Bounty* (see BIGH), with six Tahitian men and a dozen women, the ringleader being called Christian. The mixed settlement soon became the scene of treachery and crime, and at the end of ten years, in consequence of murders and reprisals, the Englishman Alexander Smith, who afterwards assumed the name of John Adams, was left alone, with eight or nine women and several children; and from them the present inhabitants (174 in 1921) are descended. Adams, changed by his tragic adventures, and sobered by his responsibilities, set about the education of his companions in Christian principles. The little colony was unknown to the world until 1808, when it was 'discovered' by Captain Folger of the American sealing ship *Topaz*; the first British vessel to visit it did not arrive until 1814. On the

death of Adams in 1829, George Hann Nobbs, who in 1828 had settled in the island, became pastor and chief magistrate, and governed well. In 1831, as their numbers had rapidly increased (to 87), and drought was feared, the islanders were induced by the British government to remove to Tahiti. But, disgusted by the immorality and other undesirable customs of their Tahitian relatives, most of them came back before long to Pitcairn Island in a vessel chartered by themselves. Then appeared the adventurer, Joshua Hill, who, claiming authority from the British government, set up a tyranny on the island till removed in 1838 by a British man-of-war. The island was annexed to Britain in 1839. In 1856 the islanders (over 190) were transferred to Norfolk Island, but a number of them afterwards returned. Pitcairn Island enjoys a lovely climate; its mountainous surface reaches 1008 feet in Outlook Ridge; the soil is fertile, and produces yams, taro, maize, sweet potatoes, bananas, pumpkins, oranges, melons, pine-apples, arrowroot, sugar, coffee. Goats and poultry run wild. There is occasional trade with passing ships. The people are expert boatmen. They are degenerating mentally but not physically from intermarriage. They are lawabiding, kindly and good-natured, and passionately fond of music. By religion they are Seventh Day Adventists. As a whole the standard of morality is low. Most adults speak English fairly well, but a peculiar patois derived from Tahitian antecedents is current. In 1898 the island was brought within the jurisdiction of the High Commissioner for the Western Pacific, and in 1902 the islands of Henderson, Ducie, and Oeno were annexed, and are included in the district of Pitcairn. The affairs of the island are conducted by a governing body consisting of a president and other members, all honorary, and chosen by vote from among the islanders by all persons male and female over the age of 18.

See Sir J. Barrow, *Mutiny of the Bounty* (1831); Lady Pelober, *Mutineers of the Bounty* (1870); T. B. Murray, *Pitcairn Island* (1854; new ed. 1885); Rosa Amelia Young [a native], *The Story of Pitcairn Island* (1895), and for the physical characteristics of the natives see article by Sir Arthur Keith in *Man* (August 1917), and *Colonial Reports - Miscellaneous*, No. 93 (1922).

Pitch. A musical sound is produced by a series of vibrations recurring on the ear at precisely equal intervals; the greater the number of vibrations in a given time the higher is the pitch (see SOUND). The pitch of musical instruments is controlled by means of a tuning-fork, consisting of two prongs springing out of a handle, so adjusted as to length that when struck a particular note is produced. It is obviously important to have a recognised standard of pitch by which instruments and voices are to be regulated; but there is, unfortunately, not the uniformity that might be desired in the pitch in actual use. For two centuries, down to about 1827, the pitch in use was nearly uniform (C = 498 to 515 vibrations per second); but from that time, owing mainly to an aim of wood-wind-instrument makers to obtain greater brilliance of tone, it constantly rose, to the detriment of soprano voices especially, till in 1859, in the Covent Garden opera band, it was a semitone higher (C = 538). The French government, on the report of a special committee, in 1859 fixed the pitch of C at 522, which continues in use in France to this day, and is known as French pitch. An international conference, where all the chief European countries were represented except France and England, was held in Vienna in 1885, which resulted in the adoption of French pitch as the standard. In 1891 the American piano-manufacturers agreed to adopt French pitch. Efforts to lower the pitch had

been made in Britain since 1859 without effect, including one by the Royal Academy of Music in 1885. But in 1896 the 'new Philharmonic' pitch was adopted, and it was agreed that the former pitch should be treated as exceptional. And in 1899 the piano trade adopted a pitch with A = 439 and C = 522. Difficulties, however, arising out of lack of uniformity continued, and in 1920 the British Musical Society recommended the universal adoption of the Queen's Hall Orchestra pitch. A = 435. America in 1926 adopted A = 440.

See A. J. Ellis, *History of Musical Pitch*, reprinted from the *Journal of the Society of Arts*, 1880, and given in abstract in *Nature* (vol. xxi.); also several articles in *Nature*, 1899.

Pitch. When the tar from wood or coal is distilled, volatile naphtha or 'spirit' is obtained at low temperatures, and as the heat is increased heavy oils and other products appear in the distillate. If the temperature reaches redness, coke or carbon is left as a residue, but if the fire is withdrawn before the distilling vessel becomes red—i.e. before the heavy oils in the tar begin to break up—the residue is pitch. A softer and tougher pitch is obtained if the fire is removed early than if the heat is continued till coking begins. In the latter case it is more black, glossy, and brittle. An elastic pitch is got from bone tar, and another from stearine residues, and both are valued by varnish and tarpanlin makers. Pitch is also obtained from natural petroleum. Wood-tar pitch is much more used in America than in England, chiefly for protecting timber from the weather and the attacks of insects. Coal-tar pitch is most largely employed in the manufacture of patent fuel like *Biquettes* (q.v.). It is also used in the manufacture of black varnishes for coating iron, and to a less extent for protecting wood and other substances, in the preparation of artificial Asphalt (q.v.), and to yield lampblack when burned. *Burgundy Pitch* is the subject of a separate article (see also *PINK*).

Pitch-blende, a velvety black mineral found in the Erzgebirge and at Redlnth, composed fundamentally of uranium oxides, enclosing a small quantity of helium, and containing in minute amount the evasive substance polonium and the still more remarkable radium. See **URANIUM**.

Pitcher-plants. See **INSECTIVOROUS PLANTS**.

Pitch Lake. See **TRINIDAD**.

Pitchstone, a name given to a type of volcanic glass, dark green, reddish brown, yellow, dark blue, or black, and occasionally showing a streaked or clouded appearance. It has a pitch-like or greasy lustre, breaks with a conchoidal or splintery fracture, and is translucent on thin edges. It is usually rich in microlites, and often contains crystalline granules and crystals of feldspar, pyroxene, hornblende, biotite, and quartz. Now and again it shows perlitic and spherulitic structures. When conspicuous crystals of sanidine (see **FELSPAR**) are abundantly present in the rock it is termed *Pitchstone Porphyry*. It occurs in the form of dykes and also as lava-flows. The name pitchstone has sometimes been given to the darker varieties of menilite, a form of opal.

Pitești, a town of Rumania, in the outlying Carpathians, on the river Argesch, 65 miles NW. of Bucharest. It has manufactures of lacquer and varnish, and, situated on the main Wallachian railway, has a considerable trade, the neighbourhood being rich in salt and petroleum, and producing good wine, fruit, and grain. Pop. 20,000.

Pith, or **MEDULLA**, is the central cylinder of tissue in the stems of Dicotyledons and Gymnosperms. In all plants where it is found it is continuous in the young state. In older plants it may

be continuous, as in the elder, oak, &c., in the form of transverse discs, as in the walnut, or wanting in the internodes, as in hemlock, &c. In very young plants it is composed of thin-walled cells filled with protoplasm and cell-sap, and takes part in the conduction of nutritive substances throughout the plant. The cell-walls usually remain very thin, the protoplasm is soon all used up within the cells, and their further growth ceases. Examined microscopically, pith cells are usually polygonal in transverse section, while they are rectangular in longitudinal section, and not much longer than broad. The ring of wood immediately surrounding the pith consists largely of spiral and annular vessels, and is known as the medullary sheath. The pith is connected with the cortex and bast by the medullary rays, which are composed of cells similar to those of the pith, and which convey sap to the inner parts of the stem. In the early life of most trees the pith serves as a storehouse for starch and other reserve substances; but as the tree becomes older the pith is crushed inwards, communication with the cortex and bast is physiologically obstructed, and the pith cells become dry and full of air.

Pithecanthropus erectus ('erect ape-man'), the name given by Dr Eugene Dubois, of the Dutch army medical service, to the animal reconstructed from fossilised remains found by him in Java. These consist of the upper part of a cranium, a left femur, and two molar teeth, and were found in 1891-2 on the left bank of the Bengawan River, near Trinil, during explorations conducted for the government of the Dutch Indies. The cranium and teeth were found close together, and the femur a few yards away and a year afterwards; but Dr Dubois believed them to belong to the same skeleton, and to be such as could only have belonged to an animal midway between man and the higher apes, and of Pleistocene age. The cranium is midway in form and size between the normal human and the gorilla's skull, and rather closely resembles that of a microcephalous idiot. The find has given rise to much discussion and difference of opinion; many authorities holding that the femur and cranium have not been proved to belong to the same skeleton, and that, while the femur is undoubtedly human, the cranium is also probably of a very low human type; others wholly or partly agree with Dr Dubois. The diversity of opinion extends to the teeth, which are large and powerful.

See Dubois, *Pithecanthropus erectus* (Batavia, 1894, in German); his Royal Dublin Society paper, 1895; *Nature*, vols. li.-liv.; Frau Selenka and Prof. Blankenhorn, *Die Pithecanthropus Schichten auf Java* (1911); and the article **ANTHROPOLOGY**.

Pithecus. See **SAKI**.

Pithom, one of the store-cities which the children of Israel built for Pharaoh (Exod. i. 11), identified in 1883 by E. Naville with Tell el-Maskhûta, on the Fresh-water Canal and railway line from Cairo to Ismailia, about half-way between Ismailia and Tell el-Kebir. The identification has since been discussed afresh by Gardiner and Naville in the *Journal of Egyptian Archaeology* (1918, &c.).

Pitlochry, a Perthshire health-resort, on the Tummel, 13 miles NNW. of Dunkeld. It has a tweed manufactory. Pop. 2200.

Pitman, SIR ISAAC, founder of the Pitman system of Shorthand (q.v.), was born at Trowbridge, 4th January 1813. He was for a time a clerk, and after some preliminary training taught schools at Barton-on-Humber (1832-39) and at Wotton-under-Edge. From 1829 he had studied stenography, and, becoming enthusiastic

for its development, had sought to publish with Bagster a manual of Taylor's system. But at a suggestion made through Bagster that he should develop a system of his own, he evolved a form of shorthand essentially phonographic and not orthographic in character. And in 1837 *Stenographic Sound-hand* appeared. The second edition was published in 1840 as *Phonography*, and under this title many subsequent editions were issued. Throughout, the cheap rate of publication which Pitman was able to obtain on account of earlier services rendered gratuitously in connection with the verification of the references in Bagster's *Comprehensive Bible* went far to popularise the system. Dismissed from Wotton because he had joined the New (Swedenborgian) Church, he conducted a school at Bath (1839-43). In the cause of phonography he wrote, travelled, and lectured untiringly, in the early days expending much of his narrow income. In addition to many manuals he issued dictionaries in connection with his system, published a history of shorthand, and printed in shorthand characters numerous standard works. At Bath he founded a *Phonographic Journal* (1842) succeeded later by other periodicals of different name, especially the *Phonetic Journal*, and established a Phonetic Institute (1843). His reform of spelling was attempted along phonetic lines. Propaganda was undertaken in a great variety of pamphlets, and many standard books were published in reformed spelling, in a phonetic printing alphabet known as 'phonotype.' In 1845 Pitman opened premises in London for the sale of his various publications. His labours in stenography were rewarded with complete success, the subject being recognised by the Technical Instruction Act of 1859, and in the Education Code of 1890, while his system came to be unapproached among stenographic systems in the extent to which it was taught and used. In his spelling reform, however, the necessity for the introduction of new printing types proved an insurmountable obstacle to general success. Pitman was knighted in 1894, and died at Bath, 22d January 1897. See *Life* by A. Baker (1908, new ed. 1913).

Piton Bark. See CARIBBEE BARK.

Pitra, JEAN BAPTISTE (1812-89), was born at Champagnelle, near Autun, taught rhetoric at Autun in 1836-41, then entered the order of St Benedict, and devoted himself to historical studies in the abbey of Solesmes. In 1858 he was sent by the pope to Russia to study the Slavonic liturgy, was created a cardinal-priest in March 1863, librarian of the Vatican in 1869, and Cardinal-bishop of Frascati in 1879. His works include *Histoire de Saint Léger* (1846), *Vie du R. P. Libermann* (1855), the invaluable *Spicilegium Solesmense* (4 vols. 1852-58), a collection of hitherto unpublished works of Greek and Latin Fathers and other early ecclesiastical writers, and its two supplements, *Analeceta sacra Spicilegio Solesmensi parata* (8 vols. 1876-91) and *Analeceta novissima* (2 vols. 1885-88), *Juris Ecclesiastici Græcorum Monumenta* (1864), and *Hymnographie de l'Église Grecque* (1867). See *Life* by Cahrol (Paris, 1893).

Pitrè, GIUSEPPE, Italian folklorist, was born at Palermo, 23d December 1841. On the outbreak of the revolution in 1860 he volunteered into the army of Garibaldi. At the close of the war he studied medicine at Palermo, and while yet a student published *Sui Proverbi Siciliani e Toscani* (1862), *Profili biografici di contemporanei Italiani* (1864), &c. In 1866 he graduated and thereafter chose a life of obscurity as a medical practitioner in a poor quarter of Palermo, devoting his days to his profession and his nights to the study of folk-

lore, especially Sicilian folklore. From its foundation in 1882 till it ceased publication in 1912, he was editor, along with Salomone-Marino, of the *Archivio per lo Studio delle Tradizioni popolari*, which became the pivot of folklore researches all over Italy; and in this journal much of Pitrè's best work appeared. As a fitting culmination of his labours the science of folklore received academic recognition for the first time, and on the creation at the university of Palermo of a chair of Demopsychology (as Pitrè preferred to call it) he was appointed first professor. He was made a senator in 1915. In 1916 he died. Among his works are the series 'Biblioteca delle Tradizioni popolari Siciliane' (25 vols. 1870-1913) and an exhaustive *Bibliografia delle Tradizioni popolari d'Italia* (1894); and he edited also the series 'Curiosità popolari Tradizionali' (16 vols. 1885-99). See Evelyn M. Cesaresco in *Folklore* (Sept. 1916) and G. A. Cesaresco, *Giuseppe Pitrè e la letteratura del popolo* (1916, in the *Archivio storico siciliano* of the Società Siciliana).

Pitri (Sansk., 'father;' plur. *Pitaras*) in Hindu religion denotes the deceased ancestor, and in the plural the body of such ancestors. In the ritual offerings are normally confined to the last three ancestors, but the whole body of ancestors is regarded as powerful to bless their descendants, and prayers are addressed to them for welfare of all kinds, especially the boon of sons, who are required in order to maintain the worship of the ancestral spirits. Though the *Pitaras* are believed in the period of the Vedas (q.v.) to dwell in heaven with the gods, and are deemed to share in some of the divine powers, they are sharply distinguished from them by mode of worship, offerings to them being normally deposited on the ground, not burned in fire, a practice doubtless derived from the older belief that the spirits of the dead remained near their buried bodies or the bones buried after cremation.

Pitscottie. See LINDSAY (ROBERT).

Pitt, WILLIAM, the elder. See CHATHAM.

Pitt, WILLIAM, the second son of the great Earl of Chatham and of Lady Hester Grenville, was born at Hayes, near Bromley, in Kent, on 28th May 1759. At the time of his birth his father was still in the House of Commons and in the very zenith of his fame, and the future statesman grew up amid associations and surroundings that were well fitted to foster that political ambition which was to be the guiding and almost the sole impulse of his life. His constitution in boyhood seemed very weak; he was never sent to school, but his education advanced so rapidly under a private tutor, that he was able to enter Cambridge when only fourteen. He was then a shy, reserved boy of exceedingly precocious talents, of irreproachable morals, and of regular and studious habits, little drawn to college society and amusements, and already distinguished by a rare self-control and concentration of purpose. From his earliest youth political life was placed before him as his ideal, and all his studies converged to that end. He became an excellent classical scholar, but he valued the classical writers mainly as a school of language and of taste; and it was observed how carefully he analysed their styles, noted down every just or forcible expression, and compared the opposite speeches on the same subject, observing how each speaker met or evaded the arguments of his opponent. Like many others he found in Locke a great master of clear and accurate thinking. His father superintended his studies with much care, and it was remembered that he specially recommended to him the sermons of Barrow as models of style and reasoning, and the histories of Polybius and Thucydides as fountains of political wisdom; that he taught him

eloquence by making him declaim the grandest poetry in Shakespeare and the speeches of the fallen angels in the *Paradise Lost*; and that he exercised him in fluency by accustoming him to translate into flowing English long passages from the classical writers. To this last practice Pitt largely ascribed that amazing command of choice and accurate English in which he surpassed all his contemporaries. When little more than a boy he was an attentive and discriminating listener to the debates in parliament. He became thoroughly familiar with the matchless eloquence of his father, and together with his brother-in-law, Lord Mahon, he supported his father into the House of Lords on the 7th April 1778 on that memorable occasion when Chatham delivered his last speech against the surrender of America, and fell down, stricken by mortal illness, on the floor of the House.

Pitt was left with a patrimony of less than £300 a year. He was called to the bar in the June of 1780, and went on the Western Circuit, but in September parliament was dissolved, and he at once threw himself into politics. He stood for Cambridge University, but found himself at the bottom of the poll; his disappointment, however, was speedily allayed, for Sir James Lowther gave him a seat for his pocket-borough of Appleby, and Pitt entered the House of Commons on 23d January 1781.

He came into the House bearing a name which was beyond all others revered by Englishmen, with the advantage of being in no way mixed up with the calamitous American war, and with talents that had already acquired an extraordinary maturity. The Tory ministry of Lord North was then tottering to its fall, crushed by the disasters in America, and confronted by an opposition which consisted of the Old Whigs who followed Rockingham, among whom Fox and Burke were conspicuous, and of a smaller body who had been especially attached to the fortunes of Chatham, and who were chiefly represented by Shelburne, Camden, and Barré. Pitt lost no time in throwing himself into the fray. He spoke on the 26th February with brilliant success in defence of Burke's Bill for Economical Reform, and on several successive occasions he assailed the falling ministry. He denounced the American war and the corrupt influence of the crown with extreme violence, but he refused to throw in his lot irrevocably with the party of the opposition, and shortly before the fall of North he publicly declared that he could not expect to bear a part in the coming ministry as he 'would never accept a subordinate position.' The words are said to have escaped from him in the heat of the debate, and the House was startled and a little amused at the arrogance of a young man who was not twenty three, who was absolutely without official experience, and who had been little more than a year in parliament, declaring that he would accept no office except in the Cabinet.

But Pitt had attained a position that placed him far above lasting ridicule. Fox spoke of him as already one of the first men in parliament. Burke said of him that he was not a chip of the old block

that he had shown logical powers that made men doubt whether he might not prove superior even to Fox; and when upon the resignation of North in March 1782 a ministry was formed under the leadership of Rockingham, combining the two sections of the opposition, Pitt remembered his pledge and refused several offers, among others the Vice-treasurership of Ireland with a salary of £5000 a year. He gave, however, a general and cordial support to the new ministers, but he at the same time brought forward the question of parliamentary reform, on which they were profoundly divided. It was a question which fell naturally to

him, for his father had been one of the first to urge it. On the 7th May he moved, in a speech of great brilliancy, for a select committee to inquire into the state of the representation, and was only defeated by 161 to 141. He soon afterwards supported a measure of Sawbridge for shortening the duration of parliament, and a measure of Lord Mahon for preventing bribery at elections.

A close personal and political connection about this time grew up between Pitt and Henry Dundas, who had been Lord Advocate under North. It proved of great importance to the career of Pitt. Dundas had none of the intellectual brilliancy or of the moral dignity of the younger statesman, but he had one of the best political judgments of his time, he had great talents both for business and for debate, and he was a most shrewd and sagacious judge of the characters of men—a gift in which Pitt through his whole life was somewhat wanting.

The Rockingham ministry lasted only for three months. The king detested it; it was from the first profoundly divided, and a bitter personal and political animosity had broken out between Charles Fox and Lord Shelburne, its two most conspicuous members. On 1st July 1782 Lord Rockingham died, and the question of leadership at once broke up the party. Fox insisted on the leadership of the Duke of Portland, a wealthy and respectable, but perfectly undistinguished nobleman, who was then Lord-Lieutenant of Ireland. The king gave the post of First Lord of the Treasury to Shelburne, who had an incomparably higher political position, and who had been a favourite friend and colleague of Chatham, though there were features in his character that already excited great unpopularity and distrust. Fox, with a considerable section of the Rockingham Whigs, at once resigned, and Pitt entered the Cabinet as Chancellor of the Exchequer in the reconstructed ministry. Public opinion generally blamed Fox, and one of the consequences of his resignation was that the House of Commons was divided into three distinct parties. There was the party of Fox, the party of North, and the party of the government, and no one of them could command a clear majority. A coalition of some kind was inevitable. Shelburne leaned towards an alliance with North, but Pitt positively refused to have any connection with the statesman whom he deemed responsible for the American war. Peace was not yet attained, but the negotiations which had been pursued by the preceding ministry were steadily pushed on. Provisional articles of peace between England and the United States were signed in November 1782, and preliminary articles with France and Spain in the following January, while a truce was established with Holland, and the first steps were taken towards a very liberal commercial treaty with the United States.

Pitt bore a leading part in the debates in parliament, and his reputation steadily rose, but the Shelburne ministry was weak, divided, and short-lived. The peace following a disastrous war necessarily involved sacrifices that were profoundly unpopular, and the character of Shelburne aggravated the divisions that had already appeared. Several resignations took place, but Pitt stood loyally by his chief, and endeavoured without success to induce Fox to rejoin the ministry. Fox, however, declared that he would never again serve any ministry with Shelburne for its head, and to the astonishment and indignation both of the king and of the country, he united with the very statesman whose expulsion from public power had been for years the main object of his policy, and whom he had repeatedly threatened with impeachment. North, irritated at the ostracism with which he had been threatened, readily entered into the alliance. Two factious votes of censure directed against the

peace were carried through the Commons by majorities of 16 and 17, and on 24th February 1783 Shelburne resigned.

Pitt had displayed the most splendid parliamentary talents in the discussions that preceded the fall of the ministry, and although he could not overthrow the compact weight of parliamentary influence opposed to him, he profoundly moved the country and placed his own position beyond dispute. On the fall of the Shelburne ministry, the king, hoping to escape the yoke of the coalition, implored the young statesman to accept the leadership, and gave him an absolute authority to name his colleagues. It was a dazzling offer, and Pitt was not yet twenty-four, but he already possessed a judgment and a self-restraint which is rarely found at any age in combination with such brilliancy and such courage, and he saw clearly that the moment of triumph had not yet come. After a long struggle and many abortive efforts the king was obliged to yield, and on the 2d April the coalition ministry was formed with the Duke of Portland as First Lord of the Treasury, and Fox and North as joint Secretaries of State.

It commanded a large majority of the votes, and included a great preponderance of the ability in the House of Commons, but the king viewed it with a detestation amounting to loathing, and the nation was profoundly scandalised by the alliance on which it rested. Pitt was offered his old post of Chancellor of the Exchequer, which he peremptorily refused. As leader of the opposition, he brought forward, in the form of resolutions, an elaborate scheme of parliamentary reform, including an increase of the county members. He was defeated by 293 to 149, but he at least succeeded in bringing Fox and North into direct collision. He brought forward another important measure for the reform of abuses in the public offices, which passed the Commons but was rejected in the Lords. The peace which was carried by the new ministry differed very little from that which they had censured when in opposition: and very soon the bill of the government for subverting in some important respects the charter of the East India Company and reorganising the government of India, produced another great change in the disposition of power.

The texture of the scheme which chiefly excited indignation and alarm was the creation by the existing legislature of a new supreme body in England, consisting of seven commissioners who were to be immovable except by an address from either house for four years, and who were during that period to have an absolute control of the patronage of India. It was contended that this measure would give the party who were now in power an amount of patronage which would enable them to overbalance the influence of the crown, dominate the parliament, and control succeeding administrations. These objections were brought forward by Pitt with great power, but with extreme exaggeration, and the king and the nation were speedily alarmed. The India Bill passed by large majorities through the Commons, but when it came into the House of Lords the king authorised Lord Temple to say that he would consider any man his enemy who voted for the bill. The communication produced an immediate effect. The bill was rejected in the Lords by 95 to 76; the ministry refused to resign, and the House of Commons supported them by large majorities; but the king peremptorily dismissed them on 18th December 1783, and next day it was announced that Pitt had been called to the head of affairs as Chancellor of the Exchequer and First Lord of the Treasury.

Pitt had already abundantly displayed his parlia-

mentary ability, his judgment, and his discretion. He was now to display in the highest degree his courage. In the eyes of nearly all the best judges in England his position was a hopeless one, and his administration was likely to be even more brief than the three which had preceded it. There was a majority of more than a hundred against him in the Commons, and the parliamentary influence behind it was so great that an immediate dissolution must have been disastrous. He was called to office by a grossly unconstitutional interference on the part of the king, and every day which he remained in office under the censure of the House of Commons added to the falseness of his position. Temple, on whom he had greatly relied, threw up the seals of Secretary of State which he had accepted, and in the House of Commons Pitt was himself at this time the only cabinet minister, while Dundas was the only considerable debater who supported him against the united attacks of North, Fox, Burke, and Sheridan. But Pitt fought his battle with a skill and a resolution that have never been surpassed in parliamentary history. A long succession of hostile votes was carried, but they failed to drive him from office, and soon unequivocal signs appeared that the country was with him. The magnanimity with which at this critical period he refused to take for himself a great sinecure office which fell vacant added greatly to his popularity. Addresses in his favour poured in from all the leading corporations in the country. The majorities against him grew steadily smaller. At last, on 25th March 1784, the long-deferred blow was struck. Parliament was dissolved, and an election ensued which swept away nearly 100 members of the opposition, made Pitt one of the most powerful ministers in all English history, and prepared the way for a ministry which lasted, with a few months' intermission, for no less than twenty years.

In this great and powerful ministry English political life assumed much of its modern aspect. The House of Commons acquired a new importance in the constitution, the people a new control over its proceedings, and the First Lord of the Treasury complete ascendancy in the government. The system of 'king's friends' controlling the ministry was finally destroyed, and when the chancellor, Lord Thurlow, attempted to perpetuate it, he was peremptorily dismissed. The skilful management of the regency question established the right of parliament to provide for the exercise of supreme power during the incapacity of the king. Direct parliamentary corruption was finally put down. Great numbers of sinecure places were abolished, and great reforms were introduced into the system of collecting the revenue and issuing public loans. The government of India was reorganised on the system of a double government, which continued with little change till the abolition of the East India Company in 1858. The whole system of taxation and of trade duties was thoroughly revised, and no minister since Walpole had approached Pitt in his complete competence in dealing with trade questions. The finances of the country, which had been extremely disorganised by the American war, became once more flourishing. A commercial treaty, based upon more enlightened commercial doctrines than any English statesman, except Shelburne, had yet adopted, was negotiated with France. In foreign politics Pitt was for some years equally successful. Some troubles that had arisen with Spain were put down by a display of prompt and judicious firmness. In conjunction with Prussia a revolutionary movement in Holland which was fomented by French influence was suppressed, and the triple alliance of England, Prussia, and Holland contributed largely to ter-

minate the wars between Sweden and Denmark and between the emperor and the Turks, though it met with a mortifying failure in its dealings with Russia. Pitt's love of peace was very sincere, but the influence of England in European councils rose greatly under his ministry, and he showed much decision and tact in extricating England from a dangerous complicity with the ambitious designs of her Prussian ally. Up to the time of the French Revolution there was no decline in his ascendancy, his popularity, or his success.

A few adverse criticisms, however, may be justly made. He cast aside too lightly on the first serious opposition parliamentary reform and the abolition of the slave-trade, and it became evident to good observers that he cared more for power than for measures, and was ready to sacrifice great causes with which he had sincerely sympathised and which he might have carried, rather than raise an opposition that might imperil his ascendancy. His once famous Sinking Fund is now universally recognised to have been thoroughly vicious in its principle; and in the latter part of his career it led him to the absurdity of borrowing largely at high interest in order to pay off a debt that had been contracted at low interest. His attempt to establish free trade between England and Ireland failed through an explosion of manufacturing jealousy in England, which obliged him to modify his original propositions in a way which was unpalatable to the Irish. More real blame attaches to him for his opposition to all serious measures to remedy the enormous abuses in the Irish parliament and for the great uncertainty of his policy towards the Irish Catholics. The great evils which grew up in England in his time in connection with the sudden development of the factory system appear never to have attracted his attention, and he made no effort to mitigate them. He created peerages with extreme lavishness and with very little regard to merit, and although his patronage was not positively corrupt, few ministers have shown themselves more indifferent to the higher interests of literature, science, and art.

When the French Revolution broke out his policy was one of absolute neutrality towards the contending parties, and this neutrality he most faithfully observed. He wholly failed, however, to understand the character and the supreme importance of the Revolution. He believed that it was merely a passing disturbance, and that its principal effect would be to deprive France for some years of all serious influence in European affairs, and almost to the eve of the great war he was reducing the armaments of England. There is no real doubt that he was forced most reluctantly into war by the aggressive policy of France in Flanders and towards Holland; but he drew the sword believing that France was so disorganised and bankrupt that a struggle with her would be both short and easy; he was almost wholly destitute of the kind of talents that are needed for a war-minister, and he had to contend with an almost unexampled outburst of military enthusiasm, and soon after with the transcendent genius of Napoleon. His belief in the probable shortness of the war and in the efficacy of his sinking fund, led him into the great error of raising his war expenses in the first stages of the war almost wholly by loans, and thus laying the foundation of an enormous increase of debt. His military enterprises were badly planned and badly executed, and he had none of his father's skill in discovering and bringing forward military talent. For some years it is true his ascendancy in parliament continued to increase. The great Whig schism of 1794 and the secession of Fox reduced the opposition to utter insignificance. But even in his domestic

measures Pitt was no longer fortunate. Through fear of the revolutionary spirit which had infected some portions of the population, he was led into repressive measures very little in harmony with his earlier career. Corn had risen to famine price, and great distress prevailed, and the government attempted to meet it by very ill-conceived relaxations of the poor-laws—by levying rates for the purpose of increasing wages, and by granting parochial relief in proportion to the number of children in a family, and thus offering a direct premium to improvident marriages. In Ireland disaffection was steadily growing, and Pitt tried to win the Catholics by measures of conciliation, and especially by the concession of the suffrage; but the opposition of the king, divided councils, and the vacillation of his own mind impaired his policy, and the injudicious recall at a very critical moment of a popular viceroi contributed largely to the savage rebellion of 1798. He then tried to place Irish affairs on a sound basis by a legislative union which was to be followed by Catholic emancipation, the payment of the priests, and a commutation of tithes. The first measure was carried by very corrupt means, but the king, who had not been informed of the ultimate intentions of his minister, declared himself inexorably opposed to Catholic emancipation, which he deemed inconsistent with his coronation oath. Pitt resigned his office into the hands of his follower Addington in February 1801; but a month later, on hearing that the agitation of the Catholic question had for a time overthrown the tottering intellect of the king, he declared that he would abandon the Catholic question during the remainder of the reign, and he resumed office in May 1804 on the understanding that he would not suffer it to be carried. His last ministry was a melancholy and a humiliating one. The war, which had been suspended by the peace of Amiens, had broken out with renewed vehemence. There was great danger of invasion, and Pitt earnestly desired to combine the most eminent men of all parties in the ministry; but the king forbade the admission of Fox. The principal followers of Fox refused to join without their chief, and Lord Grenville and his followers took the same course. Grenville, who had long been one of Pitt's ablest colleagues, was now completely alienated. A junction with Addington was effected, but it lasted only for a short time, and it added little to the strength of the ministry. Dundas, Pitt's oldest friend and colleague, had been lately made Viscount Melville. He was placed at the head of the Admiralty; but a charge of misappropriating public funds was raised against him, and in 1805 he was driven ignominiously from office. Pitt's own health was now broken. His spirits had sunk; the spell which had once surrounded him had in a great degree passed away, and although the victory of Trafalgar saved England from all immediate danger of invasion, the disasters of Ulm and Austerlitz threw a dark cloud over his closing scene. He died in his forty-seventh year on 23d January 1806. The House of Commons by a great majority voted him a public funeral and a monument in Westminster Abbey.

He was never married, and he never mixed much in general society; but in all his private relations he was pure, amiable, simple, and attractive. He was a warm friend. His temper was very equable, and till near the close of his life very cheerful. He had much ready wit, and he could easily throw off the cares of office, and even join heartily in the games of boys. He maintained to the last his familiarity with the classics, but his serious interests were exclusively political. He only once crossed the Channel, and he appears to have been

wholly untouched by the great contemporary currents of literature and non-political thought. He was not free from the prevailing vice of hard drinking, and he has been justly blamed for having allowed his great indifference to money to degenerate into a culpable carelessness. In 1801 some of his friends subscribed £12,000 towards the payment of his debts, and in the following year he sold Holwood, his country place. But these measures proved wholly insufficient. With no extravagant tastes, with no family to support, with no expensive elections, and with an official income of at least £10,000 a year, he left £40,000 of debt, which was paid by the nation. In public he was cold and repellent, and there was something theatrical in the unvaried dignity of his demeanour; but few men possessed to a higher degree the power of commanding, directing, and controlling, and he inspired the nation with an unbounded confidence both in his character and in his abilities. England has seen no greater parliamentary leader, few greater masters of financial and commercial legislation, and he was one of the first statesmen to adopt the teaching of Adam Smith. If his eloquence was very diffuse, if it showed little imagination, or depth or originality of thought, it was at least supremely adapted to all the purposes of debate, and it rarely failed in its effect. He was, in a word, a great power-minister; but in the latter part of his life an evil fate brought him face to face with problems he never wholly understood and with difficulties he was little fitted to encounter.

See the *Life* by Lord Stanhope (4th ed. 1879); books on him by Walford (1890), Lord Roschery (1891), Whibley (1906) and—especially—Holland Rose (1911, 1912, and 1925); and the famous essay by Lord Macaulay. Fortescue (in his history of the *British Army*, vol. iv., and *British Statesmen of the Great War*) has dealt severely with him as war-minister, blaming him for a long series of military disasters; he knew nothing of war, neglected the army, and relied on Dundas, though fearless, sincere, and in many respects a great man.

Pittacus, one of the 'Seven Wise Men' (q.v.) of ancient Greece.

Pittenweem, a small seaport and holiday resort of Fife, a royal (since 1542) and (till 1918) parliamentary burgh (St Andrews group), $3\frac{1}{2}$ miles NE of Elie by rail, with fisheries. There are ruins of a 12th century priory. Pop. 1800.

Pittsburgh (in accordance with the pronunciation, now often spelt *Pittsburg*), the second city of Pennsylvania, is built on a narrow strip of land where the Allegheny and Monongahela meet to form the Ohio; it extends some 8 miles up the rivers, and 2 or 3 miles down the Ohio. The business portion of the city is on a plain, less than a mile in width, along the banks, while the hills, commanding delightful views, are covered with handsome residences. In this region, where the prevailing soft shales and sandstones have been worn away by the rivers to a depth of 500 or 600 feet, the horizontal layers of coal are exposed, and access afforded to the coal-seams on the sides of the hills and at the bottom of the valleys to an extent elsewhere unknown; the great Pittsburgh coal layer, 8 feet thick, like a broad black band extends around the city 300 feet above the river. After the introduction of natural gas the former sobriquet of the 'smoky city' became a misnomer; and the clearness of the atmosphere gave an impetus to architecture, but this relief from smoke was only temporary, the gradual failing of gas restoring old conditions. Among notable buildings are the Frick office building, the Exposition Building, a large government building containing the post-office and customs offices, and a fine City-County Building, erected, owing to the inadequacy of the city hall, of white sandstone, and of the court-

house (connected with the gaol by a 'Bridge of Sighs') of Quincy granite. Of numerous churches the large Roman Catholic cathedral and Trinity Church (Episcopal) deserve notice. Pittsburgh possesses a good system of schools, and is the seat of important institutions of higher learning. The University of Pittsburgh was established in 1908 by assembling the scattered departments of what was the Western University of Pennsylvania. The Roman Catholic University of Duquesne was originally the College of the Holy Ghost. The Carnegie free library and the Carnegie Institute were built and the latter endowed in 1890 and in 1903 by Andrew Carnegie; the institute comprises a museum of science, department of fine arts, music hall, and technical schools. Among other educational institutions are the Pennsylvania College for Women and Roman Catholic and Protestant theological seminaries. There are some fine public parks, among them the Schenley Park (1890) and the Highland Park (with zoological garden).

Pittsburgh is one of the most important industrial cities in the United States. This has been added to by its absorption (1906) of Allegheny, on the opposite side of the Allegheny River. McKeesport, and many smaller boroughs, are closely allied with Pittsburgh for all business purposes. These boroughs are being gradually absorbed by the city, and in 1903 an act of legislature was passed with the ultimate object of amalgamating all these municipalities into one great city. The district, which practically extends over 25 miles up the Allegheny and Monongahela Rivers and 10 miles down the Ohio, is the great centre of the steel, iron, and glass industries of the United States. Its coalfields are very rich, and it is an extensive shipping-point for bituminous coal. In the district are the great Carnegie steel-works (at Homestead), and the Westinghouse air brake and electrical works, the largest of their kind in the world. The manufactures of the region include everything which can be made of iron, from the heaviest of guns to nails and tacks; steel in its various applications; all descriptions of glass and glassware; silver and nickel plated ware; Japan and Britannia ware; pressed tin, brass, copper, bronzes; earthenware, enameled, fire pots, bricks; furniture, wagons and carriages; brushes, bellows, electrical machinery, and mechanical supplies of all kinds; natural-gas fittings, and tools for oil and gas wells. The production of pig-iron in the district is said to be nearly a fourth of the entire product of the United States; and the enormous manufactures of iron and steel and of glass to be each about one-half. The production of radium is important. In the city is a cork manufactory said to be the largest in the world. Since about 1883 natural gas has been used for domestic and manufacturing purposes (see GAS, HEATING AND LIGHTING BY). On drilling into the earth from twelve to fifteen hundred feet a natural gas—mainly methane—rushed from the opening with a pressure of four or five hundred pounds to the square inch, which was found sufficient to force it through pipes to the houses and factories in the city. The purity of this gas, its great heating power, and its cleanliness made it a most excellent substitute for coal for domestic and manufacturing purposes. But of late the supply is less abundant, and the manufactories have returned to the use of coal, though much gas is still used for domestic purposes.

The position of Pittsburgh on the eastern border of the great Mississippi river-basin, and its facilities for penetrating to every part by river and rail, give the city great advantages for trade; and as a dépôt for exchange and transshipment many railroads centre here, among them several trunk lines.

The rivers are also of great commercial importance, and much has been spent in dams and locks on the Allegheny, Monongahela, and Ohio, to give slack-water navigation. The traffic on these rivers is enormous, chiefly coal and iron manufactures. There are also fast steamers for passenger and light traffic. Much lumber-rafting is done on the Allegheny.

History.—In the early history of America the site of Pittsburgh was a point of great interest, and was familiarly known as the 'Gateway to the West.' Here traders, settlers, and adventurers who had worked their way from Philadelphia by a chain of forts, congregated, and here flat-boats were built which carried them down the Ohio to the unknown regions beyond. In 1754 a few English traders built a stockade at the point, but were driven away by the French the following April. The latter replaced the stockade by a fort, which, in honour of the governor of Canada, they called Duquesne. It was near the present outskirts of the city that Braddock (q.v.) was surprised in 1755; and on 15th October 1758 General Grant and his Highlanders had reached the hill on which later the court-house was built when they were surrounded by the Indians and nearly exterminated. The following month, however, General Washington took possession of what remained of old Fort Duquesne, the French having fled down the Ohio, leaving the buildings in ruins. In 1759 the English commenced a large and strong fortification, which, in honour of the elder Pitt (see CHATHAM, EARL OF), then prime-minister, they called Fort Pitt. The fort is said to have cost the English government £60,000. The settlement became a borough in 1804, and in 1816 the borough was incorporated as the city of Pittsburgh. In 1892 there were terrible strikes, accompanied by not a little fighting and bloodshed, at the Carnegie steel-works. Pop. (1810) 4768; (1840) 21,115; (1870) 86,076; (1900) 321,616; (1910) 533,965 (with Allegheny); (1920) 588,343.

Pittsfield, capital of Berkshire County, Massachusetts, 151 miles by rail W. of Boston. Beautifully situated on a plateau where six lakes round the city give rise to the Housatonic River, it contains a marble court-house, a handsome atheneum, and has a fine park near its western border. Cotton and woollen goods, boots and shoes, and electrical and other machinery are manufactured. The place, too, is a summer resort. It has associations with Longfellow, and Oliver Wendall Holmes and Herman Melville lived in the neighbourhood. Pop. (1860) 8045; (1920) 41,763.

Pittston, a city of Pennsylvania, on the Susquehanna River, 8 miles by rail N.E. of Wilkes-Barre. It is in the centre of a field of anthracite coal, and has extensive mining interests, besides other industries. It is connected by several bridges with the residential West Pittston. Pop. 18,000; with adjacent municipalities it practically forms one town with a population of about 58,000.

Pituitary Body, an important organ connected with the under-surface of the vertebrate brain. It is about the size of a small bean in man, and occupies the sella turcica of the sphenoid bone. Its origin is two-fold—an upgrowth from the buccal cavity uniting with a downgrowth from the floor of the optic thalami. It seems to be in part an organ of internal secretion furnishing to the blood some substance which affects growth; its hypertrophy causes the disease of acromegaly; it also produces a secretion which passes into the third ventricle.

Pit Villages are collections of earth-caves, dug in the ground and covered with stones, wooden

or wattle lids, or clay or sods of turf. They were used by prehistoric races or by races at the lowest stages of barbarism. A good example was unearthed during the latter half of the 19th century near St Mary Bourne, north-east of Andover, in north-western Hampshire. The pits are reached by entrance shafts, sloping downwards. The pits themselves are oval or pear-shaped, varying between 22 and 42 feet in length, and are about 12 or 13 feet wide, and 5 feet high, with the fireplace in the centre. Flint and bone implements and rude-pottery have been found in them.

Pityriasis (from the Greek word *pityron*, 'bran') is the term given to certain of the squamous or scaly diseases of the skin, in which there is a continual throwing off of bran-like scales of epidermis, which are renewed as fast as they are lost. It is most common on the scalp, when it is known as *dandruff*, and must be treated with weak alkaline lotions, or, if these fail, with diluted white precipitate ointment, provided there is no inflammation. *Pityriasis rubra* is a severe disease, affecting the whole or almost the whole body, and closely allied to, if not identical with, a severe form of dry *eczema* (q.v.). *Pityriasis* or *Tinea versicolor* is due to the presence of a parasitic fungus, the *Microsporum furfurans*; it occurs in the form of irregular yellowish or brownish patches, confined to the parts of the body covered by the clothes. Microscopic examination of the exfoliated scales shows the spores and filaments of the fungus. The treatment of this affection must be solely local. Probably the best remedy is the application of a saturated watery solution of sulphurous acid gas, or of one of the sulphites dissolved in diluted vinegar, or of white precipitate ointment.

Piura, a town of Peru on the river Piura, 60 miles by rail from its port Paita. It is famous for its Panama hats, and in the neighbourhood are the largest cotton plantations in Peru. It was originally founded nearer Paita as San Miguel, by Pizarro in 1531, but the present site was afterwards adopted. Pop. 11,000. The department has an area of 15,190 sq. m., and an estimated population of over 200,000.

Pius, the name of eleven among the Roman pontiffs, of whom the following only appear to call for particular notice. **PIUS II.**, originally known as *Eneas Sylvius*, was a member of the noble family of Piccolomini, and was born in 1405 at Corsignano near Siena. His early life was stained with moral irregularities, and, like other humanists of his time, he wrote licentious poems, letters, at least one loose novel (*Lucretia and Euryalus*), and immoral comedy (*Chrysis*). At twenty-six was employed as secretary to Domenico da Capranica, Bishop of Fermo, at the Council of Basel. He soon developed a genius for diplomacy, and from 1432 to 1435 was employed in missions to Scotland, England, and Germany. Returning to Basel he sided with the council in its conflict with the pope, and on the election of the anti-pope, Felix V., was chosen as his secretary. But having been sent on an embassy to the Emperor Frederick III., he was without difficulty induced to accept office in the imperial court, and served on several embassies and other missions of importance on behalf of the emperor. Up till this time he had lived a life of unrestrained self-indulgence, but at the age of forty his passions had burned themselves out, and he was able to take orders and make his peace with Rome—the only means of obtaining a reward adequate to his ambition. He won over Pope Eugenius IV by the frankness of his apology and earned his gratitude by his adroitness in bringing back to the papacy the allegiance of the neutral German Church. Almost the last act of the pontiff

was to reward him with the bishopric of Trieste. It was not, however, till the end of 1456 that Æneas was free to leave the uncongenial atmosphere of Germany. Nicholas V. had employed him without rewarding him, but Callistus III. created him a cardinal. On the death of Callistus in 1458 he was elected pope, and took the name of Pius II. He possessed a marvellous power of adapting himself to circumstances, and the profligate and shifty intriguer made a most decorous pope. He was embarrassed by contests about Neapolitan and German affairs, but his reign is chiefly memorable for his efforts to organise an armed confederation of Christian princes to resist the progress of the Turkish arms. He died at Ancona, 14th August 1464, his last moments darkened by the failure of his great scheme. Æneas Sylvius was one of the most eminent scholars of his age. His works were published at Basel (1 vol. fol. 1551), and consist chiefly of histories, or historical dissertations and materials of history. The most interesting of his writings, however, are his letters, which throw a vivid light upon their age. The same may be said of a biographical commentary, or rather autobiography, published under the name of the copyist Gubellinus, and apparently altered by his secretary Campanus.

See *Lives* by Voigt (3 vols. Berlin, 1856-63) and Boulton (London, 1908); also two papers by Bishop Crighton in *Macmillan's Magazine*, vol. xxvii., and vol. n. (1882) of his *History of the Papacy during the Reformation*.

PIUS IV., Giovanni Angelo Medici, was born of humble parents at Milan in 1499, was educated at Bologna, and under Paul III. rose rapidly to be Archbishop of Ragusa, vice-legate of Bologna, and cardinal (1549). He was elected pope at the close of 1559. His reign is chiefly memorable as that in which the protracted deliberations of the Council of Trent were brought to a close. The famous Creed of Pius IV., or Tridentine Creed, was confirmed by a bull dated 26th January 1564. Pius died, December 8, 1565, in the arms of his nephew, St Charles Borromeo. His Correspondence with the Emperor Maximilian II. has been edited by Schwarz (Paderborn, 1889).

PIUS V., originally named Michele Ghislieri, was born of poor parents, in the village of Bosco, near Alessandria, in 1504, and at the age of fourteen entered the Dominican order. His merit was recognised by Paul IV., who named him Bishop of Sutri and Nepi in 1556, and cardinal in the following year. His austere temper prompted him as inquisitor-general for Lombardy to employ the most rigorous measures for repressing the Reformed doctrines. Under Pius IV. he was translated to the see of Mondovì, and was chosen unanimously as his successor, January 7, 1566. As pope he laboured to restore discipline and morality at Rome, reduced the expenditure of his court, prohibited bull-fights and other amusements, suppressed prostitution, and regulated the taverns of the city. He zealously maintained the Inquisition, and strove to enforce everywhere the disciplinary decrees of the Council of Trent. The whole spirit of his pontificate is most strikingly exhibited in the decree by which he ordered the yearly publication of the celebrated bull, *In Cena Domini* (1568)—an attempt to apply to the 16th century the principles and the legislation of Hildebrand. His impotent bull releasing Queen Elizabeth's subjects from their allegiance (1570) fell harmless even upon patriotic English Catholics in a heroic age. But the most momentous event of the pontificate of Pius V. was the expedition which he organised, with Spain and Venice, against the Turks, and which resulted in the

great naval engagement of the Gulf of Lepanto, on 7th October 1571. Pius died in the following May, 1572, and was canonised by Clement XI. in 1712.

PIUS VI., originally named Giovanni Angelo Braschi, was born at Cesena, December 27, 1717. He was selected by Benedict XIV. as his secretary; and under Clement XIII. he was named to several important appointments, which led finally, under Clement XIV., to his elevation to the cardinalate (1773). On the death of Clement XIV. Cardinal Braschi was chosen to succeed him, February 15, 1775. His internal administration was enlightened and judicious. To him Rome owes an attempt to drain the Pomptine Marshes, the improvement of the port of Ancona, the completion of the church of St Peter's, the foundation of the new Museum of the Vatican, and the general improvement and embellishment of the city. Soon after his accession he found himself at serious variance with the Emperor Joseph of Austria and Leopold of Tuscany, whose reforms had swept away much of the papal supremacy. The pope repined in prison to Vienna, but, though received kindly, failed to restrain the emperor from further curtailing his privileges. Soon after came the outbreak of the French Revolution and the confiscation of all church property in France. The pope launched his thunders in vain, and ere long the storm broke upon his own head. The murder of the French political agent Basseville in a street scuffle at Rome (1793) gave the Directory an excuse for the attack. In 1796 Bonaparte took possession of the Legations, and afterwards of the March of Ancona, and by a threatened advance upon Rome extorted from Pius, in the treaty of Tolentino (19th February 1797), the surrender of these provinces to the Cisalpine Republic, together with a heavy war contribution. The murder of General Dufhot of the French embassy in December was avenged by Berthier marching on Rome and taking possession of the castle of St Angelo. Pius was called on to renounce his temporal sovereignty, and on his refusal was seized, February 20, and carried to Siena, and afterwards to the celebrated Certosa or Carthusian monastery of Florence. On the threatened advance of the Austro-Russian army in the following year he was transferred to Grenoble, and finally to Valence on the Rhone, where, worn out by age and grief, he died, August 29, 1799.

PIUS VII., originally Gregorio Luigi Barnaba Chiaramonti, was born at Cesena, 14th August 1740. He entered the Benedictine order at an early age, taught philosophy and theology at Parma and at Rome, became Bishop of Tivoli, and on being created cardinal was translated to the see of Imola. After the death of Pius VI. Cardinal Chiaramonti was chosen his successor (March 14, 1800). Rome, which up to this time had been occupied by the French, was now restored to the papal authority, and in the July of that year Pius VII. entered into his capital; while next year the French troops were definitively withdrawn from the papal territory, with the exception of the Legations. Aided by his secretary, Cardinal Consalvi, Pius restored order in his states, and in 1801 concluded a *concordat* with Bonaparte. But much of the advantage thus gained by Rome was annulled simultaneously by Bonaparte's *Articles organiques*, which concerned the discipline of the church on marriage, on the clergy, and on public worship. These had never been submitted to the pope, and called forth his strongest opposition. In 1804 Napoleon compelled Pius to come to Paris to consecrate him as emperor. He was well received, but failed to get any modification of the articles, and not six months after his return to Rome the troops of Napoleon seized Ancona, and finally in February

1808 General Miollis entered Rome, and took possession of the castle of St Angelo. Ere long a decree was issued annexing the provinces of Ancona, Fermo, Urbino, and Macerata to the kingdom of Italy. The usurpation was consummated (May 17, 1809) by a decree annexing Rome and all the remaining papal territory to the French empire. The pope on June 10 retaliated with a bull of excommunication directed against the robbers of the holy see, yet without formally naming Napoleon. The unhappy pope was next removed to Grenoble, then to Savona, and finally to Fontainebleau. There he was forced into signing a new concordat, recognising the annexation of the Roman states to the empire (January 25, 1813). The fall of Napoleon allowed him to return, and on May 24, 1814 he re-entered Rome. The Congress of Vienna formally restored to him his territory, and the remainder of his reign was devoted, under the enlightened advice of Consalvi, to wise measures of internal administration. Brigandage was sternly suppressed, as well as secret societies, especially that of the Carbonari; while the Jesuits were restored, and concordats or conventions concluded with Naples, Prussia, Württemberg, and other courts of Germany. Throughout his life Pius was a model of gentleness, simplicity, benevolence, and Christian charity. He died August 20, 1823, after having broken his thigh through a fall.

PIUS IX., Giovanni Maria Mastai Ferretti, occupant of the papal chair during one of the most eventful periods in the history of the papacy, was the fourth son of Count Jerome Mastai Ferretti, and was born at Sinigaglia, May 13, 1792. His epileptic attacks rendered him unfit for the Noble Guard, whereupon he turned to the study of theology, and was admitted to deacon's orders in December 1818. For five years he presided over the orphanage of Tata Giovanni, next accompanied the Apostolic delegate Monsignor Muzi to Chile. In 1825 he returned to Rome, was made canon of Sta Maria in the Via Lata, and head of San Michele, a great hospital for destitute children. In 1827 he was made Archbishop of Spoleto by Leo XII., and transferred to Imola by Gregory XVI. in 1832. In 1840 he became a cardinal, and on the death of Gregory XVI. in 1846 was elected by acclamation to succeed him. He was avowedly the leader of the reforming party, and twelve hours after his election Cardinal Gayssene, Archbishop of Milan, reached Rome with instructions from Austria to veto his election. He took the name of Pius IX., and entered at once on a course of reforms, by which he hoped to establish the papal government on a popular but yet firm basis. His first step was to grant an amnesty to all prisoners and exiles for political offences. He next removed most of the disabilities of the Jews, authorised railways, and projected a *Consulta* or council of state, and in March 1848 published his *Statuto Fondamentale*, a complete scheme for the temporal government of the papal states by means of two chambers, one nominated by the pope, the other (with the power of taxation) elected by the people. At first the new pope was the idol of the populace. Mazzini hailed the new policy with enthusiasm, and Carlyle declared that 'the old chimera was rejuvenised!' But the revolutionary fever of 1848 spread too fast for a reforming pope, and the refusal to make war upon the Austrians finally forfeited the affections of the Romans. On November 15, 1848, his first minister, Count Rossi, was murdered in broad daylight, and two days later a threatening mob assembled in the square of the Quirinal. On the 24th the pope escaped to Gaeta, a Neapolitan seaport near the Roman frontier. A republic was proclaimed in Rome, the provisional heads of which proceeded with great moderation and wisdom to a complete

and radical remodelling of the civil government of the state. Pius from his exile addressed a remonstrance to the various sovereigns. In April 1849 a French expedition was sent to Civita Vecchia, and on July 2 General Oudinot took Rome, after a siege of thirty days. The papal government was re-established, but Pius himself did not return till April 12, 1850. From this time his government, swayed by Antonelli, was the very reverse of what it had been, and to the end of his life he continued an unhesitating and unyielding Conservative. After the war for the unification of Italy the Legations, Ancona, and a considerable part of the papal territory southward in the direction of Rome were annexed to the kingdom of Italy, but Pius persistently refused to cede any portion or to enter into any compromise.

In his ecclesiastical policy he was incessantly active, henceforward closely related with the Jesuits, and ever uncompromising in his ultramontanism; and at last he proceeded to promulgate dogmatic definitions about problems that had been left unsettled by the wisdom of the ages. He re-established the hierarchy in England, he sanctioned the establishment in Ireland of a Catholic university, and condemned the Queen's Colleges. He concluded a Concordat (q.v.) with Austria. By the bull 'Ineffabilis Deus' (1854) he decreed the Immaculate Conception (q.v.) of the Blessed Virgin Mary; his famous encyclical 'Quanta Cura' and the Syllabus (q.v.) or list of prevalent errors, appeared in December 1864. But the most important event of his pontificate was the convocation of the Council at the Vatican (q.v.) in 1869, which proclaimed the Infallibility (q.v.) of the Pope. For the last ten years the pope's temporal power in Rome had been only maintained by French bayonets; and on the withdrawal of the garrison at the outbreak of the war with Germany the soldiers of Victor Emmanuel crossed the frontiers, and, after the short delay of a feeble and half-hearted defence, entered the city amid the acclamations of the populace, and so terminated the temporal power of the pope. For the rest of his days the pope lived a voluntary prisoner within the Vatican, renewing from time to time his solemn protest. He refused the pension of £130,000 voted him by the national parliament; but his loss was in some measure compensated by the revival, as a voluntary contribution, of the ancient tribute of Peter's pence (q.v.). He died 7th February 1878, a month after Victor Emmanuel (to whom he sent the papal benediction).

See Lives by Maguire (new ed. 1878), Shea (New York, 1877), Trollope (1877), and Waplington (Ratisbon, 1878); also the articles ITALY, GARDUCCI, and MAZZINI.

PIUS X., Giuseppe Sarto, was born 2d June 1835 of humble parents at Riese near Venice, studied at Treviso and Padua, and, ordained priest in 1858, was ere long chancellor of the diocese and vicar of the chapter of Treviso. Made bishop of Mantua in 1884 by Leo XIII., and in 1893 cardinal and patriarch of Venice, he endeared himself by simplicity of life, repression of abuses, and sympathy with the poor. In August 1903 he was elected pope. Remarkable for piety and administrative activity rather than for learning, he was conservative in theology; he sanctioned the condemnation of Abbé Loisy's books. He insisted that church music should return from a florid and secular type to the sacred traditions of Plain-song (q.v.) and that church choirs should not include women. In France and Portugal complete separation of church and state, and in Spain growing toleration, led to strained relations and embarrassment. 'Modernism' in every shape was prohibited (1907, &c.), and efforts to find a *via media* between the church and modern life brought to a standstill.

He died 20th August 1914. See Life, by F. A. Forbes (1918).

PIXÉRECOURT, RENÉ CHARLES GUILBERT DE, French playwright, 'the father of melodrama,' known also as 'the Shakespeare' and 'the Corneille of the boulevards,' was born in 1773 of old Lorraine stock at Nancy, and educated there at the college, and, intended for the bar, at the university. During the French Revolution, as a youth of noble blood, he suffered in a manner much in keeping with his later work in drama many hairbreadth escapes and deadly perils. Stimulated first by Florian he wrote many plays, but though some were accepted none were played till 1797, when *Les Petits Anvergnats* was performed. In the same year *Victor*, his first melodrama, was done, and met with great success. In 1800 he wrote *Colina*, his most celebrated play, and a model for melodrama for years to come. Thereafter he produced as many as fifty-nine melodramas in addition to numerous comedies, comic operas, vanderbilts, and even tragedies. From 1802 to 1836 he held a French government appointment, and within the same period managed the Gaîté theatre at Paris for a time, and also the Opéra Comique. Law suits resulting from the burning in 1835 of the Gaîté lost him the greater part of the fortune he had acquired by his writings, and retiring to Nancy he devoted himself to preparing an edition of his best plays, publishing in 1841-43 his *Théâtre Choisi* (4 vols.), with a preface by his friend Charles Nodier and an antibiographical notice. In addition to his dramas he produced an edition of the unpublished works of Florian, wrote a learned commentary on Bret's edition of Molière, and translated works of Kotzebue and other German writers. He was also a noted collector and was one of the founders of the famous Société des Bibliophiles. He died at Nancy in 1844. See a work by Hartog (Paris, 1913).

Pizarro, FRANCISCO, born at Trujillo in Spain in 1478, was the illegitimate son of a colonel of infantry, and, still a boy, served under Gonsalvo di Cordova in Italy. In 1509 he was at Darien. He was with Balboa when he crossed the Isthmus and discovered the South Sea, led an expedition as far as Biru, to the south of the Isthmus on the Pacific coast, and eventually became a citizen of Panamá. In 1522 Don Pascual de Andagoya also reached Biru, and there collected information respecting the great empire of the Incas. Returning to Panamá to prosecute the discovery, he became so ill that he was induced by the governor to hand over the enterprise to three partners, Francisco Pizarro, another old soldier named Diego de Almagro (q.v.), and a wealthy ecclesiastic named Hernando Luque. Pizarro was to lead the expedition, Almagro was to keep open communications, and Luque was to supply the funds. Their first attempt was a failure, but in 1526 Pizarro and Almagro sailed in two vessels, with Bartolomé Ruiz, a very expert and gallant sailor, as pilot. Pizarro landed his men, Almagro returned to Panamá for supplies, and Ruiz voyaged southward, being the first European sailing in that direction to cross the equator in the Pacific Ocean. Almagro returned, and the expedition proceeded southwards. But they were not yet strong enough to form any settlement, and eventually Almagro was sent back for reinforcements, while Pizarro and part of the force remained on an island discovered by Ruiz, in 1° 57' N., called Gallo. The arrangement caused much discontent. The men complained that they were being left to starve. The governor of Panamá refused to give any further countenance to an enterprise which seemed doomed to failure, and two vessels, under Pedro Tafur, were sent to bring the people back from Gallo. Pizarro refused to

return. Drawing a line along the sand, he called upon those who remained resolute to achieve success in spite of all difficulties to come over to his side. Thirteen men crossed the line. Tafur returned with the rest to Panamá. Pizarro and his devoted little band removed to another island, called Gorgona, where there was more game and better water. For a long time the governor of Panamá refused to allow any help to be sent. At last Ruiz was allowed to sail with one small vessel. He reached Gorgona, and Pizarro embarked, full of hope. Sailing southward they reached the Peruvian port of Tumbes, and collected full information respecting the empire of the Incas. Returning to Panamá, Pizarro proceeded to Spain to apply for authority to undertake the conquest of Peru.

The capitulation between Queen Juana and Pizarro was signed on 26th July 1529. Pizarro was made adelantado and captain-general, while Almagro received the title of marshal. Pizarro took back with him his four brothers, Hernando, Juan, Gonzalo, and Francisco Martin de Alcantara. He sailed from San Lucar on 19th January 1530, and from Panamá on 28th December 1531, with three vessels carrying 183 men and 37 horses. Almagro was to follow with reinforcements. Landing at Tumbes, the Spaniards commenced the march inland in May 1532, and on 15th November entered the city of Cajamarca. The Inca Atahualpa, after defeating his brother and ending a long civil war, was in the neighbourhood, on his way to Cuzco, the capital of the empire. Pizarro captured the native sovereign by treachery, and after extorting an enormous ransom, amounting to 4,605,670 ducats, treacherously put him to death on 29th August 1533. The royal share of the treasure was sent to Spain, with tidings of the conquest. Pizarro then marched to Cuzco, and set up the young Inca Manco as nominal sovereign. On 6th January 1535 Pizarro founded the city of Lima, as the capital of his new government. He was created a marquis by the Emperor Charles V., while Almagro was empowered to occupy territory for 200 leagues from the southern boundary of Pizarro's government. But that southern boundary was not fixed. Almagro declared that Cuzco was within his grant, but was induced to forego his claim, and to undertake the conquest of Chile. The marquis was busy founding cities on the coast, while his brothers were at Cuzco, when a great insurrection of the Indians broke out. Both Cuzco and Lima were closely besieged, and Juan Pizarro was killed. For many months the Spaniards were in great danger, but in the spring of 1537 Almagro returned from Chile, raised the siege of Cuzco, and took possession of the city, claiming to be its lawful governor. The Marquis Pizarro had no intention of allowing his rival to retain Cuzco. Too old to take the field himself, he entrusted the command of his forces to his brothers, who defeated Almagro on 26th April 1538, and beheaded the old soldier soon afterwards. The property of his followers was confiscated. Pizarro remained at Lima, consolidating his power, and despatching various expeditions for discovery and conquest. But Almagro's followers were driven to desperation: they were called in derision 'men of Chile,' and the marquis treated them with contemptuous indifference. One of them, named Juan de Rada, nurtured a conspiracy for the assassination of the governor. The conspirators attacked his house during the mid-day meal, and murdered the old conqueror on 26th June 1541. The body of Pizarro was buried in the cathedral by stealth and at night.

Francisco Pizarro is one of the most prominent figures in the history of Spanish conquest in the New World. He was brave and determined, a man of inflexible constancy of purpose and infinite

resource. His followers were devoted to his service, and some of his friendships endured until death. The indelible stain on his character is the treacherous execution of the Inca Atahualpa. Although without education, he rose to the greatness of his position, and proved himself to be an able and far-seeing administrator. Falling by the hands of assassins, he was defended by devoted friends, and died as bravely as he had lived. Pizarro was never married. By the Inca princess, Inez Huayllas Nusta, a sister of Atahualpa, he had two children—Gonzalo, who died young, and Francisca, who went to Spain with her step-father, Don Francisco Ampuero, a knight who married Inez after the assassination of the marquis. Francisca married her uncle Hernando Pizarro in 1551, and by him had three sons and a daughter. Hernando, for having beheaded the Marshal Almagro at Cuzco, was imprisoned in the castle of Medina del Campo on his return to Spain, where he remained until 1560. He married his niece during his imprisonment, which could not have been very rigorous. He died at Trujillo, the original home of himself and his brothers, in 1578.

See Lives by Helms (1869) and Towle (1878); also Prescott's *Conquest of Peru* and Markham's *History of Peru* (1892).

Pizarro. GONZALO, brother of Francisco Pizarro (q.v.), was born about 1505 at Trujillo in Spain, and when a boy served with his father in Italy. He accompanied his brother Francisco in the conquest of Peru, and did very good service when the Indians besieged Cuzco, and in the conquest of Charecas. In 1539 Gonzalo Pizarro undertook an expedition to the so-called Land of Cinnamon, the forest-covered region to the eastward of Quito. He left that city with 350 Spaniards and 4000 Indians on Christmas Day, and the hardships and sufferings endured by Gonzalo and his companions have seldom been equalled. Descending the rivers Coca and Napo, Gonzalo entrusted the command of a small vessel he had built to Francisco de Orellana, one of his lieutenants, who was to go in advance and seek for supplies. But Orellana deserted his starving comrades, made the first descent of the whole course of the Amazon, and returned to Spain. Out of the 350 Spaniards that left Quito 50 deserted with Orellana, 210 died of hunger and disease, and the miserable remnant returned to Quito with their intrepid leader in June 1542.

When Gonzalo Pizarro heard of the assassination of his brother the marquis he retired to his estates in Charecas. In 1544 the new viceroy, Blasco Núñez Vela, arrived in Peru to enforce the 'New Laws.' The Spaniards were dismayed, and entreated Gonzalo to leave his retirement and protect their interests. He consented, chose an old veteran named Francisco de Carbajal as his lieutenant, and assembled a force of 400 men. The viceroy fled, and Gonzalo entered Lima in triumph on the 28th of October 1544 at the head of 1200 Spaniards, and several thousand Indians dragging the artillery. He was declared governor of Peru. Blasco Núñez Vela fled to Quito, but was closely followed by old Carbajal, and defeated and killed in the battle of Anaquito on January 18, 1546. Gonzalo Pizarro was undisputed master of Peru. Carbajal retired to Charecas to work the silver-mines.

When news of this revolt reached Spain the licentiate Pedro de la Gasca, an astute and very able ecclesiastic, was appointed to proceed to Peru as president of an 'Audiençia,' or court of five judges, and to restore order. He sailed in May 1546, and arrived at Panamá in August, where he gained possession of Pizarro's fleet by a combination of cunning and force. Gasca landed at Tumbez in June 1547. Gonzalo Pizarro, despairing of being

able to make head against the president, determined to retreat into Chile. But there was a force, under an officer named Diego Centeno, hanging on his rear; and it was necessary to dispose of it first. Centeno was utterly defeated in the battle of Huarina, near the banks of Lake Titicaca, and the doomed Pizarro was so elated at the victory that he abandoned all idea of retiring into Chile. He advanced to Cuzco, and the President Gasca approached him by leisurely marches, encamping on the plain of Sacsahuana, near Cuzco, in April 1548. On the 9th Pizarro and Carbajal marched out of Cuzco, and both sides made ready for battle. But soon there were symptoms of desertion on Pizarro's side. The desertions took place by companies and squadrons. So Gonzalo Pizarro sorrowfully took his way to the president's camp, and gave himself up. Carbajal was seized by the soldiers and hanged. Gonzalo, last of five famous brothers, was beheaded 10th of April 1548. He left, by an Inca princess, a son and a daughter. See works cited at PIZARRO (FRANCISCO).

Pizzicato, in music for the violin, &c. denotes that the strings are to be twitched with the fingers as on a harp or guitar.

Place, FRANCIS (1771–1854), the son of a dissipated London baker, bailiff, and publican, was bred a leather-breeches maker; led in a stoke, and became secretary for his and other trade associations; and as a tailor in London supported Burdett (q.v.) and became a very conspicuous and influential Radical leader. He agitated against the sinking fund, and (more effectually) against the laws preventing workmen's combinations. See Life by Graham Wallas (1898, new ed. 1918).

Placcho, in the Catholic service of vespers for the dead, is the first antiphon, which begins with the word.

Placenta, or AFTER-BIRTH, the structure which unites the unborn mammal to the womb of its mother and establishes a nutritive connection between them. The placenta is peculiarly a mammalian structure, but it is not developed in Ornithorhynchus and Echidna, which lay eggs, nor is it more than incipient in the Marsupials, which bring forth their young after a short gestation. In all other mammals it occurs in various forms, partly embryonic in its origin, partly maternal, always acting as a double vascular sponge, by means of which the blood of the mother nourishes and purifies that of her unborn young. Vague prophecies of it occur in two cartilaginous fishes and in two lizards, in which there is a connection between the yolk-sac of the embryo and the wall of the oviduct.

In the hedgehog, which is a conveniently central type of mammal, the connection between embryo and mother has the following history. (a) The outer wall of the embryonic sac is moored to the wall of the uterus by small cellular outgrowths known as the preliminary 'villi,' and minute cavities between these are bathed by the blood of the mother. (b) The growing embryo becomes encased by the double folds of the Amnion (q.v.), the inner parts of which form the 'amnion proper,' while the outer form the 'sub-zonal membrane.' Part of the yolk-sac wall fuses with this sub-zonal membrane; from the united area vascular villi grow out into the wall of the uterus, which is now much modified. Thus is formed a 'yolk-sac placenta,' as exhibited for a time by Insectivores and Rodents. (c) But the most important union between mother and offspring is that due to the union of Allantois (q.v.) and sub-zonal membrane. If there has been a yolk-sac placenta it dwindles before this new and more efficient union. From the united area vascular villi grow out into depre-

sions or crypts in the uterine wall, part of which is modified into a spongy vascular tissue. In Insectivores, Bats, and Rodents the original outer wall of the embryonic sac persists between the placental villi and the maternal blood, and mediates between them.

The final placenta thus consists (1) of a maternal part—viz. a modified region on the wall of the uterus—and (2) of an embryonic part—viz. part of the allantois, fused to the sub-zonal membrane, and giving off vascular villi, between which and the maternal blood the persistent outer wall of the embryonic sac sometimes persists and mediates.

The term 'chorion' has been used in so many senses, that it seems advisable to abandon it. It is best applied to the union of sub-zonal membrane and allantois ('true chorion'), or to the union of sub-zonal membrane and yolk-sac ('false chorion').

The embryonic part of the placenta necessarily comes away at birth, and sometimes the vascular part of the maternal placenta is also discharged when the young is born. When this is the case, the placenta is called 'deciduate,' or better 'cauducous.' When the maternal part of the placenta does not come away at birth the placenta is called 'indeciduate,' or better 'non-cauducous.' Of non-cauducous placentation two kinds are distinguished: *Diffuse*, when the villi are scattered over the surface of the embryonic sac (in Manis among Edentates, in the dugong, in Cetacea, in most Ungulates except Ruminants, in Lemnins); *Cotyledonary*, when the villi occur in patches (in Ruminants). Of cauducous placentation three kinds are distinguished: *Zonary*, when the villi form a partial or complete girdle round the embryo (in Orycteropus and Dasypus among Edentates, in Elephants and Hyrax, in Carnivora); *Discoidal*, when the villi occur on a circular cake-like disc (in most Edentates, in Insectivores and Bats, in Rodents); *Meta-discoidal*, when the villi are at first scattered, but are afterwards restricted to a disc (in Monkeys and in Man). Sir William Turner, the 'grand-master of placental research,' allots the lowest place to such diffuse forms of placenta as that of the pig, but others maintain that the discoidal type as illustrated in the Insectivora is the most primitive. In Botany 'placenta' usually means the portion of the ovary (q.v.) which bears the ovules. See also AMNION, ALLANTOIS, FETUS, MAMMAL.

Placentia. See PIACENZA.

Placitum Regium (called also *Placet*, *Exequatur*, *Lettres Patentes*) is an act or instrument executed in virtue of the privilege claimed by the government in certain kingdoms to exercise a supervision over the communications of the Roman pontiff with the clergy and people of those kingdoms, and to suspend or prevent the publication of any brief, bull, or other papal instrument which may appear to contravene the laws of the kingdom, or to compromise the public interest. The early Christian emperors, it is well known, freely extended their legislation into the affairs of the church; and one constant cause of conflict between church and state in the mediæval period was the attempt on the part of the sovereigns to control the free intercourse of the pope. In the Pragmatic Sanction in France, and in the similar legislation of Spain, Portugal, Sicily, and the Low Countries during the 15th century, the claims of the state are asserted; and among the so-called 'liberties' of the later Gallican Church (q.v.) was a certain subjection to the state in this particular. But it was in the German states that the claim was most formally embodied in the constitutional law. In England the statute of Præmunire (q.v.) was an example of the same tendency.

Placoid Fishes, an order of fishes, in the classification proposed by Agassiz, characterised by having *placoid* (Gr. *plax*, 'a broad plate') scales, irregular plates of hard bone, not imbricated, but placed near together in the skin. They are all Cartilaginous Fishes (q.v.). See SCALES.

Plagal. See PLAIN-SONG.

Plagioclase. See FELSPAR.

Plagiostom'ata. See CARTILAGINOUS FISHES.

Plague, a term used in the middle ages of all fatal epidemics indiscriminately, but now restricted to a very malignant kind of contagious fever prevailing at certain times and places epidemically, characterised by buboes, or swellings of the lymphatic glands, by carbuncles, pneumonia, and petechiæ, and now known to be due to a special bacillus discovered in 1894.

The first extensive outbreak of this disease on record took place in the 6th century A.D., and devastated the whole Roman empire. It is supposed to have started from Lower Egypt; but from this time frequent epidemics occurred in Europe, culminating in the Black Death (q.v.) in the 14th century. It continued to ravage the north and west of Europe up till the 17th century. The last outbreak in England in 1663-65 caused the 'Great Plague of London,' and spread almost all over the country (see the article LONDON). Since the end of the 17th century it has only twice visited western Europe; in 1707-14 it spread from Russia and Hungary as far as Sweden, Denmark, Prussia, and Bavaria; and in 1720-22, being introduced from Syria into Marseilles, it destroyed almost half the population there, and spread through Provence. During all this time its most constant seats, so far as is known, were the countries bordering the Eastern Mediterranean—Lower Egypt, Syria, Asia Minor, and Turkey in Europe. But from all these it has meantime disappeared. The last cases known in Egypt occurred in 1844, and in the others in 1841. It was hoped that the disease had become extinct, but since then it has occurred more than once in Arabia, Tripoli, Persia, and Mesopotamia, and in 1878 it spread to south-east Russia. It has been present in India at least since 1815, sometimes in epidemics (e.g. the 'Pali plague,' 1836-38), but most constantly in districts on the southern slopes of the Himalayas; and it is said to be always found in some parts of China. An outbreak at Hong-kong in 1894 was followed by the fearful visitation at Bombay (q.v.) and India in 1896-1908, and reached (in a mild form) even Lisbon and Glasgow in 1900.

It is the most destructive of all known epidemics. Rarely less than 50, sometimes 90 per cent. of those attacked die. 'It often carries off half the population of a town or of a district in which it prevails, and it may completely root out whole families, so that no survivor remains.' The Black Death of 1348-50 is believed to have destroyed not less than a quarter of the population of Europe.

The general symptoms resemble those of other severe fevers: shivering, rise of temperature, aching in head, back, and limbs, sickness, &c. Great weakness succeeds, with mental disturbance leading to coma or delirium. Death often occurs before any characteristic symptoms are developed; but at an early stage dark spots or patches often appear on the skin, produced by subcutaneous hemorrhages (petechiæ, ecchymoses), and bleeding may also take place from the various mucous membranes. Bleeding from the lungs, though rare in recent epidemics, was regarded as a characteristic symptom of the Black Death in its most virulent form. About the second or third day the most distinctive features of the disease are developed—viz. one or more buboes or glandular swellings, usually

in the neck, armpits, or groins; these generally break and lead to prolonged suppuration. In a few cases they are absent altogether. Carbuncles frequently develop at a later stage of the disease. Good nursing, good nourishment, free stimulation, and early opening of the buboes are helpful. There can be no doubt that it is a highly infectious disease, and that the infection may be conveyed by clothes, bedding, &c., but as a rule it is spread from place to place by rats, which also suffer from the disease. Fleas form the means of communicating the bacillus from rat to man, and probably also as a rule between one human being and another. For prevention the abandonment of town dwellings before an epidemic, life in camps from which rats are excluded, and inoculation with Haffkine's plague vaccine have proved very useful in India.

Plaice (*Pleuronectes platessa*), a common flatfish in the same genus as the flounder. It frequents sandy and muddy banks off the European coasts from France to Iceland. It often lies slightly covered with sand, but with the eyes exposed and watchful for prey. The food consists of molluscs, crustaceans, and worms, but especially of the first. It spawns early in the year, and is in best condition about the end of May. The eggs hatch near the surface, and there the youngest stages are found. After a month or so the young fish begins to swim on its left side and sinks to the bottom, moving shorewards into shallow water. From these nurseries there is a gradual movement outwards to greater depths. The male is generally mature at the end of the fourth summer, the female at the end of the fifth. It was once a common belief that shrimps were the parents of plaice. The plaice is in considerable esteem for the table, and is plentiful in the British markets. Those from sandy ground are said to be much more palatable than those from the mud. The general size weighs about 2 to 3 pounds, but much larger specimens are often caught; the coloured side is predominantly olive brown with orange spots, but the colour changes rapidly in precise harmony with that of the ground on which the fish rests; six blunt tubercles extend from the eye to the beginning of the lateral line.

Plaid. See HIGHLANDS.

Plain, a geographical term which hardly admits of precise definition. It is generally applied to extensive tracts of approximately level or undulating country, which occur at less than 1000 feet above the sea. Broad areas of similar character at higher elevations are usually termed *Tablelands* (q.v.) or *Plateaus*. This is the general rule, but when the surface of a plain slopes gradually upwards to heights of several thousand feet, the whole tract is still called a plain. As an example may be cited the great plains east of the Rocky Mountains, which fall imperceptibly away towards the east from an elevation of 6000 feet or so. Among the most characteristic plains are the wide alluvial lands of the greater rivers. But the term is extended to such low-lying regions as central Ireland, the Midlands of England, middle Europe, &c.—regions which have no great elevation and present a gently undulating surface, interrupted now and again by isolated hills, and lines of cliffs and escarpments. From the same point of view the whole interior of North America lying between the Rocky Mountains in the west and the Alleghany and White Mountains in the east, and extending from the Gulf of Mexico to the shores of the Arctic Ocean, may be called a plain. So likewise more than half of Europe is a plain that is continued into Asia and extends northward over vast regions of that continent. Plains necessarily differ much in appearance according to the nature of soil

and climate, from the dreary, sandy wastes of north Africa to the luxuriant fertility of the South American selvas. Wide regions of comparatively level ground in each of the great continents have acquired various names, such as the *Steppes* and *Tundras* of eastern Europe and Asia, the *Deserts* of Arabia and Africa, the *Savannahs* and *Prairies* of North America, and the *Llanos*, *Pampas*, and *Sileas* of South America. See DESERT.

Plainfield, a city of New Jersey, on Green Brook, 24 miles by rail WSW. of New York, many of whose business men have their homes here. Clothing, machinery, &c. are manufactured. Pop. (1860) 3224; (1920) 27,700, with the adjacent North Plainfield, 34,684.

Plain-song. **PLAIN-CHANT.** **GREGORIAN CHANT.** OF GREGORIAN MUSIC, was used in the Christian church of the West from the earliest times, is still the only prescribed form of music in all Roman Catholic churches, and has been extensively revived in the English Church since the rise of the High Church party. Its distinguishing points are (1) its recitative-like character, as opposed to what was styled *musica mensuralis*—i.e. *barred* music, with a marked and regular rhythm, which was the essential point of ancient Greek music, and more or less of nearly all modern music; (2) the *modes*, or *scyles*, in which it is written, which are more numerous and varied than the modern major and minor; and (3) its being (originally) sung in unison, though much of it is susceptible of treatment in harmony, and is now frequently (but incorrectly) so heard. It embraces music for all parts of the Roman services, from the *Accents* (nearly in monotone) proper to the various readings to the more elaborate melodies of the antiphons and hymns, and the various parts of the mass. The best known and most ancient of all is the music of the eight Tones sung to the Psalms, commonly called the Gregorian Tones. As to the origin of these many different views prevail, some ascribing them to a Greek, some to a Hebrew source, others to the early Christians; but it is extremely probable that they were actually originally derived from the music of the Temple service. As at first plain-song was handed down orally only, and the early systems of notation were very defective, it is impossible to determine how far it may have been corrupted. It was first reduced to system by St Ambrose of Milan (died 397), but much more extensively towards the end of the 6th century, by Pope Gregory the Great, after whom the chant receives its name. There have of course been large additions since. Local varieties of the proper melodies gradually sprang up, almost every diocese having an office-book peculiar to itself—e.g. the antiphony and gradual of Sarum, said to be one of the purest. The earliest known existing record of plain-song is the Antiphonarium, or rather Gradual, in the library of the monastery of St Gall in Switzerland, probably of the 9th or 10th century. Various directories have been published, notably that begun by Palestrina and finished by Guidetti, and at the Reformation the Gregorian music was adapted to the new vernacular services of the English Church by John Marbeck, who published in 1550 *The Booke of Common Praier Noted*. The fourteenth century is generally taken as the period when plain-song reached its highest perfection. A decline set in with the rise of Polyphonic (q.v.) music, and church music became dramatic, secular, and began to be accompanied by instruments. The reaction came in the 19th century, when about 1860 the Benedictine monks started to revive the Gregorian chants in their original purity and simplicity and to clear away all the accretions and alterations, dating

chiefly from the 16th to the 18th century. In 1904, Pius X. promulgated (*Motu proprio*) that only plain-song and the stricter forms of choral music (sung by male voices only) were to be permitted in church services. Anglican Chants (q.v.) are modelled on the Gregorian psalm tones.

The variety of the modes has been acknowledged by first-rate authority as affording greater resource of expression than the more modern major and minor scales; and music has been written in them by great modern composers - e.g. Bach's organ fugue in the Dorian mode, the 'Hymn in the Lydian Mode' in Beethoven's Quartet, op. 132, and portions of Debussy's *Pelléas et Mélisande*. They were derived from, though not identical with, the Greek diatonic scales, after which they have been named. The principle of their formation is that each of the seven natural sounds of the diatonic scale forms the keynote, or 'final' of a mode, which embraced that note and the seven above it. (The melodies rarely exceeded an octave, and no flats or sharps are found except an occasional B flat.) This would give us seven modes; but to each of these is attached another, in which the melody, while having the same final or keynote, instead of ascending to the octave above, ranges from the fourth below it to the fifth above. The former are called the *authentic* modes, the latter *plagal*. The difference of the modes and the effect of the melodies in them is owing, it will be noticed, to the various positions of the two semitones in the scales. The difference between an authentic and a plagal melody may be illustrated from two psalm-tunes—Newton or New London, and the Old Hundredth, in the first of which the melody lies between the keynote and its octave, but in the other between the fourth below and the fifth above the keynote. But while

the whole fourteen modes are enumerated, for the sake of completeness in theory, two of them are universally rejected in practice as defective—the two having B as their keynote. The modes are, then, arranged in pairs as follows. The 1st or Dorian (authentic) embraces the notes from D on the middle line of the bass staff to the D above, and has its keynote on D; the 2d or Hypo-dorian (plagal) has the same keynote, but its compass is from the A below to the A above it; the 3d or Phrygian (authentic) and its corresponding plagal mode, the 4th or Hypo-phrygian, have similarly their keynotes on the E of the third space of the bass staff; the 5th or Lydian and 6th or Hypo-lydian have F for final; the 7th or Mixo-lydian and 8th or Hypo-mixo-lydian have G; the 9th or Æolian and 10th or Hypo-æolian end on A; then come the rejected modes on B, styled the Mixo-loerian and Hypo-mixo-loerian; then the Ionian orastian and Hypo-ionian or Hypo-astian on C, numbered variously as 11th and 12th, or 13th and 14th, according to the rejection or inclusion of the two preceding. The Ionian is the modern major mode. St Ambrose's arrangement of the melodies was said to have been confined to the 1st, 3d, 5th, and 7th modes (authentic); while the relative plagal modes, 2d, 4th, 6th, and 8th, were added by St Gregory. In these are written the correspondingly numbered eight psalm tones; the Peregrine Tone, used only for the psalm *In exitu Israel*, is in the 9th mode. The other modes were finally added in the 8th century under Charlemagne. Each mode has its reciting note, or Dominant—not to be confounded with the modern term in Harmony (q.v.) The notation of plain-song was simple, as only one part with a restricted compass was required. Notes of two, or at the most three, shapes, indicating general differences of length,

SPECIMEN OF ANTIPHON, LEADING TO A PSALM, SET TO THE FIRST TONE, FROM THE RATISBON 'VESPERAL,' TRANSLATED AND IN MODERN NOTATION.

The musical score is written on a single staff with a treble clef and a key signature of one flat (B-flat). The lyrics are written below the notes. The score is divided into several sections:

- Intonation** (used only before verse 1): A short melodic phrase starting on D and ending on D.
- Reciting Note** (used only before verse 1): A single note on D.
- Mediation, Festal form.**: A longer melodic phrase starting on D and ending on D.
- PSALM CXII. Verse 1.**: The text "Blessed is the man that feareth the Lord." The melody starts on D and ends on D.
- Second Reciting Note.**: A single note on D.
- Ending, 1st form.**: A short melodic phrase starting on D and ending on D.
- Reciting Note.**: A single note on D.
- Mediation.**: A longer melodic phrase starting on D and ending on D.
- Verse 2.**: The text "His seed shall be mighty upon earth, &c." The melody starts on D and ends on D.

(Tones 3, 4, 7, and 8 have more than one form of ending.)

were set on a staff of four lines, the name of the mode being indicated, and one of the lines chosen to represent the keynote.

See the *Psalterium musicale* (1889, *et seq.*) published by the Benedictines of Solesmes and the *Grammar of Plain-song* (1905) by the Benedictines of Stanhope; J. Pothier, *Les Melodies grégoriennes* (1881); P. Wagner, *Einführung in die Gregorianischen Melodien* (1911); Gavaert, *La Mélodie antique* (1905); Gastoué, *L'Art grégorien*; T. Heuvel, *Manual of Plain Song*, and his primer; and the publications of the English Plain-song Society (founded 1888).

Planarian, a term practically co-extensive with Turbellarian, and applicable to the members of the lowest class (Turbellaria) of worm-like animals. They live in fresh and salt water and sometimes in damp earth. They are unjointed 'worms' with a ciliated skin; the food-canal is often branched, but has no posterior opening; from the simple brain two lateral nerves extend backwards; the body-cavity is undeveloped; there are no respiratory or circulatory organs; the excretory system consists of branching tubes ending in ciliated cells; all but two genera are hermaphrodite. Their simplicity is well illustrated by the fact that some multiply by dividing into two, while a fragment of others may re-grow the whole. In *Microstoma lineare* a temporary chain of eight or sixteen individuals is sometimes formed by budding. In diet they are carnivorous, but a few are parasitic—suggesting the next class of Trematodes. As illustrative genera we may note *Planaria*, in fresh water; *Vortex* and *Convoluta*, with green species (the colour being probably due to partner Alga); *Gnada*, with hints of segmentation; *Microstoma* and *Stenostoma*, the two unisexual genera; *Graffilla* and *Anoploleium*, parasitic; *Bipalium* and *Geodesmus*, on land; *Coleoplanea* and *Ctenoplanea*, in some ways suggestive of the Coelenterate *Ctenophora*. The genus *Planaria* has furnished material for very important physiological experiments bearing on the problem of natural death. See C. M. Child, *Senescence and Rejuvenescence* (Chicago, 1915.)

Planché, JAMES ROBINSON, playwright, archaeologist, and herald, was born of Huguenot descent in London, 27th February 1796. He wrote extravaganzas, designed dresses for C. Kemble's revival of *King John* (the first time that an historical drama had been produced in the costume of its period, furnished English words for Weber's *Der Freischütz*, and in 1826 for *Oberon*; and after 1831, when he was engaged by Madame Vestris at the Olympic, wrote nearly 200 dramatic pieces—most of them adaptations, but a large number original dramas (e.g. *Charles XII.*) and extravaganzas. Of the latter five volumes were published in 1880. In 1843 he helped to found the British Archaeological Association, and for many years he contributed valuable papers to the proceedings of the Society of Antiquaries. In 1854 he was made Rouge Croix Pursuivant, and in 1866 Somerset Herald; in 1872 he received a civil list pension of £200 a year. He died 30th May 1880.

Among Planché's works, besides his *History of British Costumes* (1834) and *Cyclopedia of Costume* (2 vols. 1876-9) are his *Royal Records*, or a *Chronicle of the Coronations of the Queens Regnant of England* (1838); *The Pursuivant of Arms* (1852); and *The Conqueror and his Companions* (2 vols. 1874). See his *Recollections and Reflections* (2 vols. 1872).

Planchette, a thin heart-shaped piece of wood mounted on three props, two of which are furnished with cursors, and one is a pencil which may be made to trace characters on a sheet of paper by resting the fingers upon the instrument. Its use is as a supposed medium for spiritualistic communications. See the *Proceedings of the Psychical Research Society* (1888, &c.).

Planck, MAX, mathematical physicist, born at Kiel in 1858, became professor there and afterwards at Berlin. Out of his work grew the Quantum Theory (q.v.), and from him 'Planck's Constant' takes its name.

Plane (*Platanus*), the sole genus of the family *Platanaceae*. The species of plane are few: natives of temperate climates in the northern hemisphere: tall trees, with deciduous large palmate leaves and smooth whitish bark, which annually scales off in large pieces.—The Oriental Plane (*P. orientalis*), a native of Greece and the East, was planted by the Greeks and the

Fig. 1. — Oriental Plane (*Platanus orientalis*): a, branch; b, flower; and c, fruit, on larger scale than a.

Romans as an ornamental tree, no other tree, indeed, commanding equal admiration; and for centuries the youth of Greece assembled under its shade in the groves of Academeus to receive lessons in philosophy. The plane is still planted for shade

Fig. 2. — Branch of *Platanus occidentalis*.

and ornament in the south of Europe. Many fine trees exist in England, but they were at one time much more numerous, great part having died in the end of the 18th century. The spring frosts and the insufficient duration of the summer for the proper ripening of the wood render Scotland less suitable for its cultivation, yet there is a tree at Gordon Castle, Forcubers, 66 feet high. No tree better endures the atmosphere of a large city, and there are no finer trees within London than its plane-trees (*P. acerifolius*, a hybrid between *P. orientalis* and *P. occidentalis*). Noble specimens are to be seen in Hyde Park and

Russell Square, in London, and the avenue of the Thames Embankment is formed with this tree. In the East *P. orientalis* attains an immense size. One tree in the meadow of Bnyukdere, on the banks of the Bosphorus, is 141 feet in circumference at the base, extends its branches 45 feet from the trunk, and is believed to be more than 2000 years old. The wood of the plane, when young, is yellowish white; when old it is brownish, fine grained, takes a high polish, and is esteemed for cabinet-making. A rich alluvial soil and the vicinity of water are most suitable to this tree. The North American Plane, or Buttonwood (*P. occidentalis*), is a very similar tree. It is the largest deciduous tree of the United States, and abounds on the banks of the great rivers of the middle states. Its timber is not very valuable, and is very liable to decay. A tree of this species on the bank of the Thames, in Chelsea Hospital gardens, is 115 feet high, with a trunk 5 feet in diameter. The name plane-tree is commonly given in Scotland to what in England is known as the Sycamore (*Acer Pseudoplatanus*), which resembles the true planes in its foliage, but is neither a plane nor a true sycamore, being really the Greater Maple. See MAPLE.

Planetarium. See ORRERY.

Planetoids, or ASTEROIDS. See PLANETS.

Planets (Gr. *planētēs*, 'a wanderer') are those heavenly bodies (including the Earth) which belong to our solar system, and revolve in elliptic orbits round the sun. They were distinguished in very early times from the *fixed stars* by their wanderings or movements relative to these bodies, which to the naked eye show no change of position from day to day or year to year (see STARS). The planets at present known are, in the order of their distance from the sun, Mercury, Venus, the Earth, Mars, Jupiter, Saturn, Uranus, and Neptune, and a large number of minor planets whose distances from the sun are between those of Mars and Jupiter. Six of these—Mercury, Venus, and the Earth (which was not, however, then reckoned as a planet), Mars, Jupiter, and Saturn—were known to the ancients; Uranus was discovered by Sir William Herschel (q.v.) in 1781; and Neptune, whose existence and position were predicted theoretically by Leverier and Adams, was discovered by Dr Galle in 1846. The minor planets, of which 1000 are known, have all been discovered since 1st January 1801, and most of them in recent years by photography. Six of the planets, the Earth, Mars, Jupiter, Saturn, Uranus, and Neptune, are attended by one or more satellites; Uranus (generally), Neptune, the minor planets with rare exceptions, and all the satellites except the moon are invisible to the naked eye. The visible planets can be at once distinguished from the fixed stars by their clear, steady light, while the latter have a sparkling or twinkling appearance. The planets, as observed from the Earth, generally move from west to east among the stars, but for certain periods from east to west, remaining nearly stationary for some time at the point where progression ends and retrogression commences. This peculiarity in their movements was carefully studied by the Greek astronomers, and was represented by them as the result of an epicyclic or combination of circular movements (see PROLEMY). The system of Copernicus, by assuming the sun, and not the Earth, as the centre about which the Earth and planets revolved, explained with admirable simplicity these puzzling movements. The planets move round the sun in ellipses, the sun's position being at a focus of each ellipse. The eccentricity of the ellipse differs for each planet, but is generally small; in fact, none

of the orbits of the major planets, if drawn accurately to scale on a sheet of paper, would be distinguished by eye from a circle, though the position of the sun would be seen to be distinctly eccentric. Another peculiarity of the planetary orbits is the near coincidence of the planes in which they move with the ecliptic or plane in which the Earth moves round the sun. This applies specially to the larger planets, which are consequently always to be found in a narrow belt of the sky extending on both sides of the ecliptic. Among the minor planets there are wide divergences—e.g. the orbit of Pallas has an inclination of $34^{\circ} 42'$ to the ecliptic. All the planets move round the sun in the same direction. According to Kepler's Laws (q.v.) the nearer a planet is to the sun the shorter is the time of its revolution. The arrangement of the planets in the solar system bears no known relation to their relative size or weight; for, though Mercury, Venus, and the Earth follow the same order in size and distance from the sun, yet Mars, which is farther from the sun, is much less than either the Earth or Venus, and the minor planets, which are still farther off, are the least of all. Jupiter, which is next in order, is by far the largest, being about one and half times as large as all the others together; and as we proceed farther onwards we find Saturn less than Jupiter, and Uranus than Saturn, though Neptune, the remotest, is somewhat larger than Uranus.

With reference to their distance from the sun, as compared with that of the Earth, the planets are divided into *superior* and *inferior*. Mercury and Venus are consequently the only 'inferior' planets, all the others being 'superior.' The inferior planets must always be on the same side of the Earth as the sun is, and can never be above the horizon of any place (not in a very high latitude) at midnight; they are always invisible at their superior and inferior conjunctions, except when, at the latter, a *transit* (see SUN) takes place. The superior planets are likewise invisible at conjunction, but when in opposition they are seen with the greatest distinctness, being then due south at midnight. The time which elapses from one conjunction to its corresponding conjunction is called the *synodic period* of a planet, and in the case of the inferior planets must always be greater than the true period of revolution.

Mercury, the planet which is nearest the sun, is also, with the exception of the minor planets, the smallest (being only three times the bulk of the moon), and performs its revolution round the sun in the shortest time. Its greatest elongation is never more than $27^{\circ} 45'$, and except in high latitudes it is never above the horizon more than two hours after sunset, or the same time before sunrise; on this account, and from its small apparent size ($5''$ to $13''$), it is only occasionally observable by the naked eye in Great Britain. It shines with a peculiarly vivid white or rose-coloured light, and shows some indistinct markings. Its year (or sidereal period of revolution round the sun) is 87.969 days.

Venus, the next in order of distance and period, is to us the most brilliant of all the planets. Its orbit is more nearly a circle than any of the others, and when at inferior conjunction it approaches nearer the Earth than any other planet. Its apparent angular dimensions vary from $10''$ at the superior to $66''$ at the inferior conjunction. Its greatest elongation varies from 45° to $47^{\circ} 12'$, and therefore it can never be except in high latitudes above the horizon for much more than three hours after sunset, or the same time before sunrise. While moving from the inferior to the superior conjunction Venus is a *morning star*, and during the other half of its synodic period an *evening star*.

When this planet is at an elongation of 40° its brilliancy is greatest, far surpassing that of the other planets, and rendering a minute examination through the telescope impossible. At this period it sometimes becomes visible in the daytime, and after sunset is so bright as to throw a distinct shadow.

(Mars) are of great interest. In any attempt to explain them it should be remembered that Mars has a very slight atmosphere and is at a much lower temperature than the Earth. Mars is generally observed near opposition when it is full. Its phases are clearly seen in a moderate sized telescope

when it is a month or two from opposition. The amount of phase never exceeds one-seventh of the diameter of the planet.

Minor Planets.—After Mars in order come the minor planets (see below), formerly called Planetoids or Asteroids.

Jupiter, the next in order, is the largest of all the planets, its bulk being more than 1400 times that of the Earth, though, from its small density, its mass is only 300 times more. After Venus it is the brightest of the planets and the largest in apparent size, its angular diameter varying from $30''$ to $50''$. When looked at through a telescope it is seen to be considerably flattened at the poles, owing to its rapid revolution on its own axis; and its surface is crossed in a direction parallel to its equator by three or four distinct and strongly marked belts, and a few others of a varying nature. Spots also appear and remain for some time on its surface, by means of which its revolution on its axis has been ascertained. Separate spots give, however, slightly different periods (some even move past one another), but 9 hr. 55 min. 21 sec. may be taken as the mean period. Jupiter has nine satellites—the sixth

seventh both discovered by Perrine at Lick Observatory in 1905, one by Melotte at Greenwich in 1908, and one by Nicholson at Lick in 1914. The four discovered by Galileo, easily observable through an ordinary telescope, have proved of service in the determination of longitudes at sea and of the motion and velocity of light (see ASTRONOMY). The smallest of these four is about the same size as our moon; the others are considerably larger. The newly discovered ones are less than 50 miles in diameter. The year of Jupiter is 4332.584 days.

Saturn, next in position, is about 745 times larger in volume, though only about ninety times greater in mass, than the Earth. Its apparent diameter when in opposition is $20.3''$, and there is a considerable flattening towards the poles. Its surface is traversed by dusky belts much less distinctly marked than those of Jupiter, owing doubtless in great part to its inferior brightness; its general colour is a dull white or yellowish. The most remarkable peculiarity of Saturn is its ring, or series of concentric rings, each one parallel and in the same plane with the others and with the planet's equator. The ring is *distinctly* separable into three parts; the two outermost are bright like the planet itself, while the innermost, called the 'Dusky' or 'Crape' ring, is only discernible through a powerful telescope. The rings are composed of a multitude of small satellites in rapid revolution round the planet. They are not always visible when Saturn is in the 'opposite' half of its orbit, for when the plane of the rings passes between the Earth and the sun, their dark surface is turned towards us, and when the sun is in their plane only the narrow edge is illuminated; in both of these cases the ring is invisible from the Earth. Its plane being inclined at an angle of 28° to the ecliptic, we see the two surfaces of the ring alternately for

Fig. 1.—Diagram showing the comparative sizes of Sun and Planets.

Astronomers have repeatedly attempted to ascertain the nature and characteristics of its surface, but its brightness so dazzles the eyes as to render the correctness of their observations at best doubtful. From the changes in the position of dusky patches on its surface, which have been frequently noticed, it is concluded that it revolves on its axis, and that its equator is inclined to the plane of its orbit at an angle of 75° ; but many astronomers doubt these conclusions. Its year is 224.7 days. It is uncertain whether Venus rotates around its axis in 23 hours 20 minutes, or so slowly that it always presents the same face to the sun. Both Venus and Mercury necessarily exhibit phases like the moon. For *transits* of Venus, see SUN.

The *Earth*, the next planet in order, will be found under its own name; it has a single satellite, the *Moon* (q.v.). Its year is 365.256 days.

Mars, the first of the superior planets, is much inferior in size to the two previous, its volume being about $\frac{1}{4}$ th of the Earth's. After Mercury, its orbit is much more eccentric than those of the other planets. When it is nearest to the Earth (i.e. in opposition) its apparent angular diameter is $30''$; when farthest from it (i.e. in conjunction), not more than $4''$. Mars revolves on its axis (which is inclined at an angle of $28^\circ 27'$) in 24 hours 37 minutes, and its year is 687 days long. In 1877 Hall of Washington discovered that it had two satellites, now named Phobos and Deimos. It shines with a reddish light, and is a brilliant object in the heavens at midnight when near opposition; when seen through the telescope markings are visible on its surface, while at each pole is a spot of white. These spots decrease when most exposed to the sun, and increase under the contrary circumstances. The linear markings called *canals* observed by Schiaparelli and Lowell (see Lowell's

periods of fifteen years at a time; and at the middle of each period the rings attain their maximum obliquity to the ecliptic, and are then best

Fig. 2.—Saturn, as observed by Trouvelot with the 26-inch Washington Refractor.

seen from the Earth. The invisibility of the rings when seen end-on proves them to be very thin. The thickness may be estimated at 50 miles. The diameter of the outer ring is 176,000 miles. Saturn has nine satellites. Two of these were discovered by Herschel in 1787 and 1789, four by Cassini in 1672 and 1684, one by Huyghens in 1655, one by Lassell in England and Bond in America in 1848, one by W. H. Pickering in 1898. The ninth has a period of 550 days, and its mean distance from Saturn is 8 million miles, and it revolves about the planet in a retrograde direction. The discovery of a tenth small satellite by Pickering has not been confirmed. The satellites are all situated outside of the ring, and the largest of them is nearly equal to the planet Mars in size. The year of Saturn is 10,759.219 days.

Uranus, the next planet in position, was discovered accidentally by William Herschel on 13th March 1781, and was named 'the Georgium Sidus' and 'Herschel,' but these names soon fell into disuse. It is about seventy-two times greater than the Earth in volume, and thirteen times in mass; but, though so large, its distance is so much greater in proportion that astronomers have been unable to gain much information concerning it. No spots or belts have hitherto been discovered on its surface. It is attended by four small satellites, two of which were discovered by Sir W. Herschel, and two by Lassell. The year of Uranus is 30,686.820 days.

Neptune is the next and outermost member of the solar system, and, at a distance of nearly 3000 millions of miles from the centre of the system, slowly performs its revolution round the sun, accomplishing the complete circuit in about 165 solar years. It is about ninety times larger than the Earth, but from its extreme remoteness is of almost inappreciable magnitude when seen through an ordinary telescope. It was the disturbance in the motion of Uranus caused by the attractive force of this planet which led Leverrier and Adams to a calculation of its size and position, on the supposition of its existence; and the directions which were given by the former to Dr Galle of Berlin, specifying its exact position in the heavens, led that astronomer to its discovery on 23d September 1846 (see ASTRONOMY). Mr Lassell of Liverpool discovered that Neptune is attended by one satellite. The satellites of Uranus and Neptune differ from the planets and from other satellites except the small eighth satellite of Jupiter and ninth of Saturn, in the direction of their motion, which is from east to west, and in the case of the former in planes nearly perpendicular to the ecliptic. Both Uranus and Neptune were observed

long before the times of Herschel and Leverrier, but they were always supposed to be stars. Uranus is known to have been observed by Flamsteed between 1690 and 1715, and Neptune by Lalande in 1795.

In astronomical tables, almanacs, &c. the planets, the Sun, ☉, the Moon, ☾, are for convenience denoted by symbols instead of their names, as follows: Mercury, ☿; Venus, ♀; Earth, ⊕; Mars, ♂; the minor planets, in the order of their discovery, ①, ②, ③, &c.; Jupiter, ♃; Saturn, ♄ or ♅; Uranus, ♅; Neptune, ♆ or ♇.

MINOR PLANETS, the name given to that numerous group of very small planets which is situated in the solar system between Mars and Jupiter. Till the 19th century they remained undiscovered; but for some years before their existence had been suspected, mainly owing to the remarkable hiatus in the series of the planetary distances when compared with the Law of Bode (q.v.). On 1st January 1801 the first of them (Ceres) was detected by Piazzi of Palermo, and his success roused his brother astronomers to search for more planets. Their search was successful, for Olbers (q.v.) discovered two (Pallas and Vesta) in 1802 and 1807, and Harding one (Juno) in 1804; but as all researches for some time subsequent to 1807 were unavailing, astronomers gradually allowed themselves to settle down into the belief that no more minor planets remained to be discovered. But the detection of a fifth (Astræa) by Encke in 1845 revived the hope of fresh discoveries, and from this period no year (excepting 1846) has passed without adding to the list. The number known at the beginning of 1851 was 13, of 1861 was 62, of 1871 was 112, of 1881 was 219; at the end of 1923 there were over 1000. This great success of the astronomers of our time is due to the systematic manner in which the zodiacal belt has been explored, and to the ease with which a body moving among the stars can be detected on a stellar photograph.

The magnitudes of these bodies are in general very small. Barnard at the Lick Observatory was able to see perceptible discs for Ceres, Pallas, Vesta, and Juno, and measured their diameters as 485, 304, 243, and 118 miles respectively. There are probably a few more whose diameters are greater than 100 miles, but generally speaking they are not more than 20 miles. From the absence of a perturbing effect on Mars the total mass has been determined to be less than $\frac{1}{3000}$ th of that of the Earth. Some of their orbits are much more eccentric than any of the major planets, and they are also inclined at greater angles to the ecliptic. Among the planets of greatest eccentricity are Polyhymnia (0.34) and Adhira (0.38), whose aphelion distances are about double of their perihelion distances. The greatest inclination to the ecliptic of any of the orbits is that of Pallas (35°). The orbits of the minor planets present several features of dynamical interest. Their mean distances range over a considerable space between the orbits of Mars and Jupiter. But there are gaps where none are found, probably due to the commensurability of orbits at those distances with that of Jupiter. Six of the minor planets—Patrioclus, Hector, Achilles, Nestor, Agamemnon, Priamus—appear to oscillate about a position 60° from Jupiter, thus exemplifying the possibility recognised in theoretical dynamics of the sun, Jupiter, and a small planet remaining permanently at the angles of an equilateral triangle. The planets Victoria, Iris, and Sappho, and still more Eros, are of interest because their near approach to the Earth has made them the means by which our most accurate knowledge of the sun's parallax, and thus of the scale of the solar system, has become known. The perturba-

tions of the planet Polyhymnia have been used to determine the mass of Jupiter.

For a Table of the periods, distances, size, density, &c. of the planets, see SOLAR SYSTEM. See also ORBIT, PHOTOGRAPHY, and SPECTRIUM.

Planimeter, a machine for measuring areas on a plane. The best-known form, Amster-Lafon's, consists of two rods hinged together. The extremity of the one rod is fixed, so that the free extremity of the other is able to trace out any form of curve limited only in size by the dimensions of the apparatus. The theory of the instrument depends upon the fact that, as the free end is made to trace out the boundary of any closed area, the hinged end oscillates to and fro along a curve, but traces out no area. Rigidly attached to the rod whose one end traces out the plane area is a graduated roller fixed with its axis of rotation parallel to the line joining the hinge and the tracing point. As the closed curve is being described the roller rotates because of the lateral movement of the rod; and the difference of the readings before and after the tracing has been accomplished gives a number proportional to the area that has been gone round.

Plankton is the name for all organisms in the sea, whether plant or animal, floating at the mercy of winds and currents, and unable to propel themselves. Nekton is the term for those that can swim, but plankton is sometimes used loosely to include these. It occurs in all depths, but is most abundant from the surface to about 100 fathoms. Both plants and animals occur, the former chiefly unicellular and microscopic, but the latter including representatives of most classes of marine animals. The distribution of plankton depends on temperature, salinity, light, currents, and the abundance of food. Much investigation is needed on these lines, especially as regards its distribution in depths. The proportion between plants and animals varies, but plants are generally more frequent than animals in polar waters, while the converse is true in tropical and often in temperate seas. Phytoplankton is present from the surface to about 500 fathoms, the depth to which light penetrates. Its importance in the economy of the ocean is great, as it is practically the only plant-life and the ultimate source of food for all animal-life. Phytoplankton consists mainly of unicellular algae, including diatoms with a siliceous test, peridinians with no test, many of them phosphorescent, and coccoliths and rhabdospheres with calcareous shields. Diatoms are most abundant in coastal and polar waters. In the latter they may render the surface waters green or brown and opaque over large areas. Peridinians are mainly oceanic. Among the microscopic animals represented in plankton are foraminifera with calcareous tests, which are tropical and sub-tropical, and radiolaria with siliceous tests. Larger organisms in great abundance are copepods and ostracods among crustaceans, pteropods among molluscs, medusæ such as the Portuguese man-of-war, as well as many pelagic eggs or larvae of echinoderms, annelids, bryozoa, crustaceans, and fishes.

Plantagenet, surname of an Angevin house which in 1154-1485 reigned in England. The name was adopted by Geoffrey, Count of Anjou, husband of Matilda, daughter of Henry I., from the badge of a sprig of broom (*planta genista*) which he wore. See articles on the several kings, from Henry II. to Richard III., also ROSES (WARS OF THE)

Plantain. For the tropical plantain (*Musa*), see BANANA. The English plant so called belongs to the Plantaginaceæ, a family of dicotyledons, mostly herbaceous; the leaves forming rosettes, flat and ribbed, or taper and fleshy; the flowers

usually in spikes, and generally hermaphrodite the calyx 4-parted, persistent; the corolla hypogynous, membranous, persistent, its limb 4-parted; the stamens four, inserted into the corolla, with long filaments; the ovary free, of a single carpel, 1-4-celled; the cells containing one, two, or many ovules; the fruit a membranous capsule with a lid. The testa of the seeds abounds in mucilage, which is easily extracted by boiling water. There are about 200 known species, diffused over all parts of the globe, but most abundant in temperate and cold countries.

The most important genus is *Plantago*, the species of which often receive the English name Plantain. Six of this genus are found in the United Kingdom, including *P. Edmundstonii*, which has been found in Orkney and Shetland. The Greater Plantain, or Waybread (*Plantago major*), is one of the commonest of British plants; a perennial, with broad ovate stalked leaves and long cylindrical spikes, growing in pastures, waysides, &c. It is very widely diffused over the world. Its seeds are a favourite food of birds.—The Ribwort Plantain, or Greater Plantain (*Plantago major*).

Ribgrass (*P. lanceolata*), is another very common British plant, forming no small part of the herbage of many meadows and pastures. Its leaves are lanceolate, and taper at both ends; its spikes are short, ovate or cylindrical, and placed on long angular stalks. Its seed is acceptable to cage-birds. This is the plant commonly known as 'bullies,' or 'sodgers,' the striking off the heads (or spikes) of which is a favourite amusement of children.—The mucilage of the seeds of *P. Isopaghalia* and of *P. Psyllium* is much used in India in catarrhs and other complaints; and *P. Psyllium*—called Fleawort, and its seeds Fleaseed—is cultivated in France for the sake of this mucilage, which is used by paper-stainers in preference to that obtained from linseed, and is also extensively used by muslin manufacturers for stiffening their goods. The plant has a branched spreading stem and recurved leaves. For Water Plantain, see ALISMACEÆ.

Plantain-eaters, or TOURACOS (*Muscophaga*), a family of arboreal African birds. The flight-feathers yield a peculiar crimson pigment called turacin, containing copper, and so soluble that it is washed out in heavy rains. Another remarkable feature of touracos is that they are the only birds with green pigment, though green colour is common enough. Representative genera are *Turacus*, *Muscophaga*, *Gallirex*. An interesting fossil form, *Necornis*, occurs in the middle Miocene of France. They are shy, restless birds, noisy except during rain or in the midday heat, feeding mainly on fruits and insects, making flat twig nests like pigeons. For Turacin, see Church, *Phil. Trans. Roy. Soc.*, 1869, 1893.

Plantation. See FORESTRY, PRISONS, TRANSPORTATION.

Plant-houses are garden structures designed for the protection and cultivation of the plants of warmer climates than our own. Apart from the style of architecture, a plant-house must be so constructed as to admit a maximum of light to the interior; there must also be ample provision for ventilation, and means for maintaining such atmospheric temperature as is necessary to the plants that are to be cultivated in it. Glass, wood, and iron are the materials of which plant-houses are made. Masonry is not essential in the erection of plant-houses, but it is very generally employed to give stability, durability, and architectural effects. Glass obviously is the most important material: the larger the amount of it that enters into the structure of a plant-house the better adapted will it be for the cultivation of plants; the means for securing the maximum of light is thereby provided, and its regulation is then under the control of the cultivator.

Plant-houses are broadly divided into three classes—viz. hothouse or plant-stove, intermediate house, and greenhouse. The structure of each class may be the same in all respects except in the power of the heating apparatus. In the hothouse it must be adapted to create and sustain tropical temperatures irrespective of the temperature of the outer air; in the intermediate house the heat of extra-tropical and temperate countries must be provided; and in the greenhouse all that is required of the heating apparatus is the exclusion of frost or the maintenance of a minimum temperature of 40° F. Hothouses are either dry or moist, according to the needs of the plants to which they are devoted. Thus there may be tropical orchid houses, tropical fern houses, tropical aquatic-houses fitted with tanks of heated water, for *Victoria regia*, *Nymphæa*, and the like; but the more common class of stove is that in which the internal arrangements are made with the view of accommodating a large variety of plants, having considerable diversity of constitutional requirement. The intermediate house may be subdivided in the same way into the cool orchid-house, the cool fernery, &c.; but the more commonly it is adapted to the wants of miscellaneous plants, and very often indeed it is used temporarily for tropical plants during their period of rest, when a lower temperature and less humidity than those of the stove are desirable. The greenhouse may be a health-house if exclusively devoted to the culture of Cape heaths (*Erica*) and kindred plants; and so on.

The conservatory is a plant-house in which a miscellaneous collection of plants, after having been grown elsewhere, is placed in order to display the beauty of flowers and foliage. It may be either cool or hot, according to the classes of plants accommodated in it. Being usually a place of resort, or a lounge accessible from the drawing-room or some other part of a house, its architectural features should be in harmony with those of the building; but due regard should also be had to the providing of ample light, and perfect ventilation. The propagating house is a plant-house devoted to the rearing of the several classes of plants indicated in the foregoing. It may be heated or cool, and differs from the ordinary plant-house chiefly in being more restricted in atmosphere. It is fitted with close glass-cases, fixed or portable, for the purpose of preventing exhaustion, by the atmosphere, of cuttings and other subjects temporarily destitute of roots. An essential feature of the internal arrangements of the propagating house is a bed or beds filled with sand, coconut fibre, or any other cleanly material, in which the pots containing cuttings may be plunged

at will to prevent evaporation from their sides and fluctuations of temperature in their contents. These beds are usually provided with hot-water pipes, tanks, or flues below, for the purpose of giving bottom heat when required.

Plantigrades. See BEAR, CARNIVORA.

Plantin, CHRISTOPHE, an eminent printer, was born at St Avertin, near Tours, in 1514, and settled as a bookbinder at Antwerp in 1549; some six years later he began to print. The books that came from his office are distinguished for their accuracy and beautiful workmanship and finish. His business prospered, and he had often twenty presses or more in active operation at once. The most noted of all his publications is the *Biblia Polyglotta* (8 vols. 1569-73), which was printed under the personal superintendence of Arias Montanus, the court chaplain of Philip II. of Spain. Plantin's editions of the Bible in Latin, Hebrew, and Dutch, and editions of the Greek and Latin classics, are scarcely less celebrated. He died at Antwerp, 1st July 1589. He had set up printing-establishments in Leyden and Paris, and these, with that in Antwerp, were carried on by the husbands of his daughters. His office in Antwerp remained in the possession of the family of John Moretus, his son-in-law, until it was bought by the city in 1876 for 1,200,000 francs; out of it was created the 'Musée Plantin' (1877).

See Lafo by Max Rooses (in French, Antwerp, 1892); Baeker and Kuslens, *Annales de l'Imprimerie Plantinienne* (Brussels, 1865); Degeorge, *La Maison Plantin* (3d ed. Paris, 1886); and *Correspondance de Plantin* (edited by Rooses, Ghent, 2 vols. 1884-86).

Plant-lice. See APHIDES.

Plants. It is not possible to frame a complete definition of a plant as opposed to an animal; the most obvious distinction is that a plant is fixed, while an animal moves; and though it is quite true that plants form that kingdom of nature which is characteristically passive in its life, while the animal life is more vigorous, yet there are many animals, such as a sea-anemone, which are as fixed as a plant; and all plants are sensitive to the sun's rays, and move in response. Nor can we make a formal distinction between them in terms of the food they require; for although it is true that plants live upon simple unorganised materials, the salts and water of the soil, and the carbonic acid and oxygen of the air, and indeed serve as the source of all food for animals, yet there are many parasitic plants which live on the juices of other living creatures. What chiefly makes such a definition impossible is that at the bottom of the ladder of life there are innumerable living creatures which it is a mere formality to call either plants or animals. From such creatures as these it is possible that the two great kingdoms of nature have been evolved step by step in constantly diverging lines. But the diversity of nature of plant and animal life is such that they are mutually helpful to each other; plants having the means of feeding upon the carbonic acid of the air, using the carbon and giving out the oxygen, thus forming matter for the life of animals, who in return, by breathing out carbonic acid, help to keep the air in a fit state for plants. This mutual relation of the two kingdoms finds another expression in the aid that insects and some birds give to the higher plants, for in their search for honey they become covered with pollen, and carrying it from flower to flower secure cross-fertilisation; while it is probable that the bright colours of flowers have been to a certain extent evolved by the selection which the insects that visited them have exerted.

The four great divisions of the vegetable kingdom are Thallophyta (Algae and Fungi), Bryophyta

(Mosses and Liverworts), Pteridophyta (Ferns, Horsetails, &c.), Spermatophyta (Gymnosperms and Angiosperms). For subdivisions see those heads.

See also BOTANY, PHYSIOLOGY (VEGETABLE), BIOLOGY, ROOT, FLOWER, &c.

MOVEMENTS OF PLANTS.—These may be divided into—(1) those due to the unequal growth in growing organs; (2) those due to unequal expansive energy of turgid tissues in mature plants. Each group may be subdivided into spontaneous movements (autonomic), caused by diffuse stimuli, and induced movements (paratonic), caused by unilateral stimuli. The whole phenomenon is a manifestation of irritability, a fundamental property of living matter.

Spontaneous growth movements are seen in the spiral course executed by the root and the shoot during elongation, described as circumnutation. It is by virtue of circumnutation that twining plants are able to climb round a support. The leaves in a bud are packed close, due to greater growth on the underside (hyponasty); later, the maximum growth shifts to the upper surface (epinasty), and the bud unfolds. Tendrils, before they coil, nutate and become hooked. The opening of crocuses on a bright day and the opening of tulips brought into a warm room are examples of thermonastic movements. These curvatures are primarily the result of stimulation, which, in spite of the homogeneous external conditions, causes unequal growth of the two sides of the growing organ.

Induced Growth Movements. *Gravity.*—A bean root marked in equal divisions and placed horizontally bends downward at the region of growth. This geotropic curvature is a response to gravity and not to the weight of the root, as a horizontally placed root will still bend though supported by mercury. Slow rotation, so as to cause the direction of gravitation to alter constantly with regard to the sides of the root, results in horizontal elongation. Substitution of centrifugal force for gravity results in elongation of the root away from the centre of rotation. Tap roots are positively geotropic, lateral roots are diageotropic. Stems are generally negatively geotropic. Reversal of the response takes place in certain flowers—e.g. poppy and narcissi, and, after fruiting, in the groundnut and cyclamen. Various explanations have been put forward to account for the perception of gravity. A root with its tip amputated does not respond, indicating that the perceptive organ is in the apex. Haberlandt found large starch grains which were movable, and propounded a statolith theory of perception. Czapek put forward a chemical explanation. Small attempts to account for the different behaviour of root and of shoot by the difference in acidity of the continuous phase in each, and brings in an electric explanation.

Light has a retarding influence on growth; consequently unilateral illumination of window plants results in a bending of the stem toward the light (positive heliotropism), while the leaves place themselves at right angles to the incident rays. The goat's-head and the sunflower follow the sun's course. The roots in cress and ivy are negatively heliotropic. In oats seedlings and in those of Canary grass the tip of the cotyledon is the light perceptive organ. In Crucifer seedlings the top of the hypocotyl performs the function. Curvature takes place in the growing region, and there is thus a transmission of stimuli in plants. Haberlandt has suggested that the epidermal cells function as lenses and account for light perception. Heliotropic curvature is not confined to green plants, as the sporophores of Pilobolus are positively heliotropic and discharge their spores towards the light. Movements of the chloroplasts, in response to variations in the intensity of light, occur in the Algae,

mosses, fern prothalli, and in *Oxalis* and *Lemma*. Motile organisms, such as zoospores, are positively heliotropic and phototactic in moderate light, but the responses are reversed in strong light. Oscillaria, diatoms, and desmids place their long axis parallel to the incident rays.

Temperature.—The roots of cress and maize bend towards the warmer side of an unequally heated box. The opening and closing of many flowers is brought about by changes in temperature.

Moisture.—Inequalities in the amount of soil-water cause roots to grow to the moister soil. The moulds are positively hydrotropic until spore formation, when the response is reversed. Myxomycetes move toward the moister position (hydrotaxis), but at spore formation move to the drier situation.

Contact, Wounding, &c.—Roots grow away from an obstruction. The coiling of tendrils is due to the stimulus of contact. The traumatic response of a wound root has been named the Darwinian response, in honour of Charles Darwin, who first described it.

Chemical.—The movement of the male gametes in the fern towards the archegonium is due to a chemical attractive substance. The phenomenon is known as chemotaxis. The chemotaxis of the spermatozooids is paralleled by the chemotaxis of the pollen tube in the higher plants.

Spontaneous Movements of Variation.—The lateral leaflets of the telegraph plant (*Dioscorea gyans*) twist through an elliptical path, and earn the plant its popular name. Slower movements are exhibited in the terminal leaflet of red clover and the wood sorrel.

Induced Movements of Variation.—The leaves of the sensitive plant (*Mimosa pudica*), which droop at the slightest touch, are the best example. The two halves of the leaf of *Dionaea* close on a touch like a man-trap, while the tentacles of *Dioscorea* and the edges of the leaves of *Pinguicula* roll inward more slowly over a captured insect. The stamens of a large number of plants—Berberis, Mahonia, Opuntia, Cerus, Portulaca, Helianthemum, Mesembrianthemum, and Sparmannia—move when touched, thus dusting their insect visitors with pollen. The filaments of the Cynaree contract, and the stigma shoots the pollen out like a pop gun. The flaps of the bifid stigma of *Mimulus* close rapidly when touched, thus enclosing pollen.

The sleep movements (nyctotropic) seen in many leaves in the Leguminosae, Oxalida, and Marsilea, and the closing of certain flowers, are due to the stimulus of changing light intensity, or change of temperature, or both stimuli combined.

MEDICINAL PLANTS.—The study of plants with genuine or fancied curative properties is as old as human thought and sickness. Even animals seek such medicines, and it must be remembered that our early ancestors were much more familiarly acquainted with fruits and seeds, roots and bulbs than are their more carnivorous descendants. But, while it may be contended that ancient medical treatment was in great part a natural return to more primitive vegetarian diet, it is obvious that men would be quick to profit by a wide and often costly experience of plants with special properties, poisonous and emetic, tonic and narcotic, excitant and sudorific. While botanical science is partly rooted in the garden, no small part of it has grown out of a primitive materia medica. Assyrian and Babylonian cuneiform plant-lists mention about 250 vegetable drugs. In the writings of Hippocrates (460-377 B.C.) and those to which his name is extended 236 medicinal plants are recorded: the list swells in the works of Aristotle (387-322 B.C.) and Theophrastus (371-286 B.C.), while the 'Materia Medica' of Dioscorides (born in the 1st century A.D.) includes the

names and partial descriptions of about six hundred. His work remained authoritative for fifteen centuries, and was continued on the one hand through the herbalists like Gerard and Culpepper into the botanical side of the modern pharmacopœia, on the other hand through such early botanists as Cæsalpinius into the independent—doubtless too independent—science of botany.

In connection with medicinal plants there are many interesting chapters of history with which the student should make himself acquainted—the weird stories of the old traffic in vegetable poisons; the magicians' use of narcotics and excitants; the mystical doctrine of Signatures (q.v.), according to which plants bore signs indicative of their virtues; the gradual decay of herb gathering and the loss of much of the ancient traditional lore; the persistent record of the old uses of plants in both technical and popular names, such as Pulmonaria, Sanicula, Tussilago, and wound-wort, scurvy-grass, gontweed; the additions to the British flora by such importations as belladonna; the elimination from the modern pharmacopœia of many vegetable drugs whose value was only fanciful; the relegation of others to the list of spices; the modern discovery or rediscovery of the potencies of Calabar bean, cinchona, coca, and many more.

See BOTANY, MATERIA MEDICA, PHARMACOPEIA.

DISEASES OF PLANTS (*Phytopathology*). Scientific investigation of the diseases of plants has not till recently been so widely and systematically followed up as the importance of the subject deserves. Bacteria and parasitic fungi are the chief causes. Wet rot in the potato, rot in the bulbs of the hyacinth and the onion, wilt in the tomato and other solanaceous plants, and in the cucumber; crown-gall in the rose, vine, and hop; striping in the tomato, leaf-spot in the bean, yellows in the peach, and pink decay in wheat may be cited as examples of diseases of plants ascertained to be caused by bacteria. The bacteria may act by dissolving away the cementing material that holds the cells together, or by damping the conducting elements, by exciting hypertrophy, or by destroying tissues.

Parasitic fungi are extremely numerous, and are as varied in their action and peculiar in the parts they affect as they are numerous. Some attack the roots, others the stem and branches, while the flowers, the several organs of reproduction, and the fruit are each liable to be attacked by some particular parasite which induces disease. They are almost always local in their action, and it is very rare to find a case in which the whole organism of a plant is affected in the sense that man and other animals are said to be constitutionally diseased. Instances there are in varieties of cultivated plants of something extremely like constitutional proneness to disease. Certain varieties of peas and wheat are extremely liable to mildew. A similar tendency to canker is seen in some varieties of the apple, and certain varieties of the potato are more liable to succumb to disease than others. On the other hand, resistant or immune varieties of many plants have been found or produced.

In the suddenness of outbreak and the rapidity with which they spread when they first appear in a country or locality, there is a strong resemblance in some plant diseases to certain epidemics in animals. And this resemblance is carried further in tracing the subsequent history of notable plant diseases. They appear, like epidemics in animals, to exhaust their extreme virulence after a time. The cases of attack may continue numerous and frequent, but the type is less severe. The potato disease of 1845 has continued annually in greater

or less severity since that time; but from that year, and the two or three years immediately succeeding, it has ceased to be so formidable. The vine disease (*Uvulina necator*: see OIDIUM), the hollyhock disease (*Puccinia malvaearum*), the celery disease (*P. Apii*), all made their appearance suddenly with such virulence and widespread rapidity as to threaten extinction of the species attacked, but are now sources of neither trouble nor alarm.

The direct action of parasitic fungi in causing disease in plants is through the mycelium or spawn injuring the host plants either by depriving them of nourishment, by impairing their power of assimilation, or by abnormally accelerating or retarding growth. The extent of injury inflicted is extremely variable, in some cases exterminating in degree, and in others, though widespread and general, having little ill effect upon the health of the subjects. Adverse external circumstances—such as unsuitable temperature, excess of dryness or moisture in the air and in the soil, deficiency of light, the presence of deleterious elements in the soil or of noxious gases in the atmosphere—by debilitating the plants render them more liable to attacks of fungi, and aggravate their severity.

The effects of disease in plants are extremely various. One of the most common manifestations of the presence of parasitic fungi in the tissues is *hypertrophy* in the parts affected. This may be either local or general; the roots, the stems, the leaves are all liable to this peculiar disorder. Many of the conifers are particularly subject to hypertrophies in disease. The so-called *Cedar-apples* of the United States, which occur in great abundance on the branches of *Juniperus virginiana*, are caused by *Gymnosporangium macropus*. They are reniform tumours, and originate by the mycelium entering a leaf and growing downwards into the bark of the smaller branches. Its presence acts as a source of irritation to the cells. The stem and branches of *Juniperus communis* are subject to hypertrophies caused by *G. clavariæforme*. This is frequently to be observed in Britain, and the enlargements are of a very persistent character, and in effect impede the supply of sap to the branches beyond them. Similar tumours occur on the branches of the silver fir, which are caused by the spawn of *Peridermium elatum*. But the most remarkable example of hypertrophy in connection with the diseases of any of the conifers is that which occurs in the larch disease, which is caused by the spawn of *Præzia Wilkommii* (or *Dasycephala calycina*). The presence of the threads in the cortex, cambium, and woody tissues causes their death; but hypertrophy of the tissues of the surrounding parts is set up. The fissuring of the bark of the affected parts follows in due course, and the branch attacked eventually dies, and sooner or later also the tree succumbs to the disease. There are many other examples of this form of plant disease, nor are they peculiar to ligneous plants, but occur in humble herbaceous subjects, such as the violet, anemone, ranunculus, grasses, and so on.

Anbury (q.v.) and Club-root are the common names given to a disease which attacks the turnip, cabbage, cauliflower, and other members of the Cruciferae. It assumes the form of tumours on the roots generally. They increase in number and in size as the plants grow, but eventually the plants cease to develop and die; the tumours becoming foetid masses, and leaving the spores of the fungus (*Plasmidiophora brassicae*) in the soil.

Diseases of plants of traumatic origin are those which result as a consequence of wounds which may have been received by a tree or shrub. Nature may have succeeded in covering over the wound,

and superficially all may appear well; but it often occurs that some fungus, perhaps harmless to the subject while its bark is intact, finds a lodgment in the wound, and sets up parasitic disease.

Canker, most familiar to some of us upon the apple-tree, is not uncommon upon the oak, ash, elm, beech, &c. It is caused by the same fungus (*Nectria ditissima*) in every case.

Of large conspicuous fungi attacking wood exposed by wounds examples are to be found on the ash and the elm in *Polyporus squamosus*, and in two species of *Agaricus*, *A. ulmarius* and *A. adiposus*, the latter attacking wounded ash and beech trees, and the former wounded elm-trees, while *A. ostreatus* attacks injured laburnums.

Rot or gangrene in the stems of fir and other trees is caused by *Armillaria mellea*, the mycelium of which finds its way into the woody tissues by the roots and gradually ascends the trunk, inducing decay either in the form of moist or dry rot. See PHOSPHORESCENCE.

Atrophy occurs in the pine, in wheat, and in other plants in consequence of attacks of various minute parasitic fungi. *Uredo puitorygonum* attacks the pine tribe, and by arresting the flow of sap at the points attacked starves the branches beyond, causing sterility and eventually death. In like manner *Puccinia graminis* attacks the straw of wheat, and renders the ear abortive. But sterility is also caused by parasitic fungi attacking the organs of reproduction directly. Certain species attack the male organs only, as *Ustilago violacea*, some, such as *Thecaphora hyalura*, affect only the female organs, while *Ustilago carbo* effects the destruction of all the floral organs.

A singular feature in the economy of many of the minute parasitic fungi is that in one stage of their existence they are capable of living only on one kind of host plant, and at another stage on a species quite distinct; so distinct indeed, as in the case of the *Puccinia* above named, that in one form it attacks the barberry and in another stage wheat. It has long been a matter of common observation among farmers in Britain, on the continent of Europe, and in parts of the United States, where the common barberry has been introduced, that the proximity of that shrub to wheat-fields had some mysterious connection with mildew in wheat. In the state of Massachusetts a law was passed in 1760 enjoining the extirpation of the shrub, in consequence of the belief that it caused or at least intensified the wheat disease. The problem was solved by De Bary in 1864, who, by placing the promycelial spores of the *Puccinia* (wheat-mildew) on the barberry produced *Ecidium berberidis*, the mildew which frequently attacks that shrub. Since that many species have been shown to have this heterocercous habit.

Cures for plant diseases are as yet empirical rather than scientific. In many cases the subject affected is fatally smitten before evidence of disease is visible. Mildew, which is one of the most common phenomena of plant disease, is the fructification, the final stage, of the parasite. The mycelium, whence the mildew springs, is working its deadly function on the plant in parts which external remedial applications cannot effectively reach. In many cases of plant disease the affected subject dies without any apparent cause; investigation after death may discover it, but too often also it reveals the fact that our knowledge does not enable us to prescribe a cure. Internal remedies are yet undiscovered. Soot, sulphur, soap are safe external remedies for mildew—that is, they destroy the pest without injuring the foliage on which it preys—but do not always eradicate the disease. *Bordeaux Mixture* and *Paris Green*, both having copper for their base, are very effectual externally

against fungi, but require to be used with great caution. The only safeguard against attack appears to be the maintenance of the plant in perfect health.

There are separate articles in this work on plant-diseases such as ERGOT, RATHANIA, RUST, SMUT, and under the names of the plants affected—e.g. POTATO; and on the various insect-pests which induce diseased conditions, such as the Aphides and Phylloxera. See also PARASITIC PLANTS; Marshall Ward, *The Diseases of Plants*, (1901); F. L. Stevens, *Plant Disease Fungi* (1925); and manuals by Massee (1915), and Stevens and Hall (1910).

PLANT-LORE. There is abundance of traditional lore associated with all kinds of trees, plants, and flowers. The study of this throws much light on many puzzling survivals in popular folklore, and Mannhardt (1831-80) and Sir J. G. Frazer have shown its importance for part of the problem of primitive religion. It is not infrequent among Australians and Red Indians to find the Totem (see TOTEMISM) taking the form of a plant or tree, and for these the individual shows his reverence by refusing to gather or destroy them. We find the worship of trees widely prevalent among savages everywhere, and we have ample evidence that it was an important element in the religion of all the families of the Aryan stock. The oak was especially associated among Aryan peoples with the thunder-god—Zeus, Thor or Tinnur, the Lithuanian Perkunas, whose name is cognate with *Quercus* (See BOMFACE, DOBONA, DRUIDISM). The sacred fig-tree of Romulus in the centre of Rome, the *Ficus religiosa* of India, and the sacred groves of the Semitic and pre-Semitic races still surviving at Carthage a century after Augustine are ready examples of tree-worship from sufficiently wide centres of civilisation. The primitive mind of the savage readily conceives of a tree as animated by a conscious soul cognate with his own, and he may regard the tree either as its permanent outward organism or merely its characteristic dwelling-place. Buddhists do not include trees among sentient beings possessing mind, but recognise the existence of the genius of the tree, and the Buddha himself was such as often as forty-three times during his transigrations. The reverence paid to the famous Bo-tree (q.v.) shows how fundamental a fact is tree-worship, which undoubtedly formed a large part of the old indigenous religion amalgamated by the new philosophical faith. But none the less are the sacred tree and grove to be found within the range of Semitic and Aryan influences, and the obstinate revival, even under the shadow of purer rites, of the Canaanitish Asherah worship proves how deeply they were rooted in the old religion of the land. From all sides we find evidence at once of the great antiquity and uniformity of the worship of trees, whether for the services they render to man, for their venerable antiquity, their form, for particular qualities ascribed to them as containing the seeds of fire, for their situation, as on sombre and lonely mountain-tops, or for their association with certain phenomena, as plagues and pestilences, or certain events in the history of the homestead. In the growth, life, decay, and death of the plant the primitive man easily sees an analogue to his own life-history, and herein we may find the philosophy of the widespread rustic rites associated with marriage and with the birth of children. The custom of scattering flowers and the fruits of the field over the footsteps of a newly-married pair conveys an obvious reference to the belief in the reproductive powers of vegetation and to the fundamental postulate of all sympathetic magic that any effect may be produced by imitating it. Primitive ideas of the fertilising and fruit-bearing powers

of nature led easily, according to Mannhardt, to the belief that each tree or plant possesses spiritual as well as physical life, being tenanted either by semi-divine spirits or by the ghosts of the dead; and a natural generalisation of this notion made plants and trees collectively the abode of particular inhabitants—an example of animism developing into polytheism. A forest-god has been deduced from a mere tree-son, both alike regarded as powerful to produce rain or sunshine, to cause fruits to spring and cattle easily to bring forth their young. A still higher generalisation gave a belief in a genius of plant-life or forest-life, or, higher still, a genius of growth or fertility in general. This universal genius of growth was symbolised by a bush or tree, brought in triumph from the forest, gaily decked, and solemnly planted near the homestead or in the village. We have thus seen both the spirit incorporate in the tree, suffering and dying with it, and the tree considered as the mere dwelling-place of the god; but still further in many cases we find the tree-spirit regarded as detached from the tree, and, through a confusion of his vegetable and anthropomorphic representations, clothed in human form as a man or a girl decked with flowers—the May King, Queen of the May, the Old Woman or Corn-mother of German harvest-fields, the Jack in the Green of young London sweeps, and the like. The existence of those Corn-spirits which especially haunted and protected the waving corn we see dimly recognised in characteristic ceremonies of an English harvest-home, and in the German custom of leaving the last sheaf of rye in the field as a tribute to the Roggenwolf. The French and German custom of the Harvest May, in which a branch or tree decked with ears of corn is carried home in the last wagon from the harvest-field and hung on the roof of the farmhouse till next year, is closely cognate with the *corvonné* of ancient Greece, and suggests a parallel with some of our own old harvest customs. In the wassailing of apple-trees, still practised in many parts of England with libations and incantations, a boy is sometimes sent up among the branches, perhaps a reminiscence of the tree-spirit, or perhaps of human sacrifice.

Sympathetic affinities between plant and animal life strongly impress the primitive imagination; we find them playing an important part in many cosmogonies, as in the Iranian account of how the first human pair grew up as a single tree, the fingers or twigs of each one folded over the other's ears, till the time came when they were separated, and infused by Ahuramazda with distinct human souls. Other mythical cosmogonic trees that need only be named are the heavenly fig-tree of the Vedas, and the ash-tree Yggdrasil of Norse mythology. In some places trees are informed when their owner dies, and an apology formally made to them by the woodcutter before he fells them; and every one is familiar with the custom of planting a tree at the birth of a child, and the notion of a sympathetic relation subsisting throughout life betwixt the two. The trees planted by kings and queens on their visits to various towns, and the Trees of Liberty planted to mark a new political régime, convey unconsciously a survival of the same sympathetic symbolism. The belief that a child's rickets can be cured by passing him through a cleft ash-tree still lingers obstinately in corners of England, and stories of trees giving forth human grouts and exuding human blood are common in folk-tales everywhere. Families, as well as individuals, have tutelary or guardian trees; and Hytén-Cavallius, for example, tells us that the three families of Linnaeus (or Linné), Lindelius, and Tiliander were all called after the same tree, an ancient linden on lime which grew at Jonshoda Lindergård. When

the Lindelius family died out one of the old lime's chief boughs withered; after the death of the daughter of the great Linnaeus the second main bough fittingly bore leaves no more; and when the last of the Tiliander family expired the tree's active life came to an end, though the dead trunk continued to be highly honoured.

We see then how natural is the notion of symbolising the genius of vegetation under the form of a tree, and thus, as has been shown, we find some hint at the real philosophy underlying the joyous old-world May-day usages, the Maypole decked with streamers, round which young men and maidens danced in chorus, and not less the high ceremonies attending the harvest-home. Even our Christmas-tree, which originally made its way into England and France principally through the influence of Prince Albert and the Duchess Helen of Orleans, is really nothing but a survival of an ancient German custom of heathen origin, and we may safely disregard the foolish theory of its being Christian because the 24th of December chances to be consecrated to Adam and Eve. One legend relates how Adam brought from Paradise a fruit or slip from the Tree of Knowledge, from which sprang the tree from which the Cross was made—an example of a process of myth-making after the fact to which we owe not a few beliefs and customs not understood. But many plants have received a kind of religious consecration from the name of some saint whose festival fell on the day on which they were gathered. And Christianity, like Buddhism, early showed a marvellous adaptability in the way in which it adopted popular rites of an earlier religion, and subtly rebaptised them as its own. Many remnants of primitive superstitions survive in the local English names of plants and flowers, chiefly in connection with the faunes, the devil, the Virgin, and the Cross, and we have a great wealth of association from one cause or other between saints and flowers, as St Agnes with the Christmas rose, St Joseph of Annalhea with the Glastonbury thorn, St Patrick with the shamrock, the Virgin with the white lily, just as Thor had his oak tree, Venus her myrtle. Curious and interesting, but obscure, are the notions of magical properties connected as persistently with some plants as medicinal properties are with others. Most prominent in European folklore are the elder, the thorn, and the rowan or mountain-ash; but strange properties are still ascribed to the rosemary, vervain, St John's wort, mandrake, asphodel, and to 'fern-seed'; and many flowers lend themselves through some obscure inherent fitness to special methods of divination. The doctrine of Signatures (q.v.) opens up a special chapter.

Sir J. G. Frazer's *Golden Bough* contains a contribution of the greatest value to a scientific knowledge of the worship of vegetation, but it seems probable that a serviceable enough theory has been carried too far, and at any rate many of its conclusions remain to be tested by the fresh generalisations of a later day. Its starting-point is the mysterious story of the Arician lake, well known through Turner's picture and the allusion in Macaulay's *Lory of the Battle of Lake Regillus*. The lake occupies the site of the ancient sanctuary of Diana Nemorensis. In its grove grew a sacred tree, from which whoever succeeded in breaking off 'the Golden Bough' had the right to challenge the priest of the sanctuary to single combat, and, if victorious, to reign in his stead. Sir J. G. Frazer sees here a survival of ancient tree-worship, the priest being an incarnation of the spirit of the tree, which passed continuously on his being killed into a new and more vigorous incarnation. He finds it also an evidence of primitive human sacrifice, and

identifies the Golden Bough with the mistletoe growing on the oak—the only thing in nature which could bring Balder to his doom. He has with unequalled learning and ingenuity traced many cognate customs in classical antiquity, as well as parallels in our modern rustic spring and midsummer customs, and finds the same significance of the death and resurrection of vegetation under the various forms of the Greek myth of Demeter and Persephone, the Syrian Astarte and Adonis, the Phrygian Cybele and Attis, the Egyptian Isis and Osiris.

Planudes, MAXIMUS. See ANTHOLOGY.

Planula. See HYDROZOA.

Plasencia, a decayed town of Spain, in Cáceres province, 130 miles W. by S. of Madrid and 43 NE. of Cáceres, is surrounded with double walls (1197), has a fine Gothic cathedral (1498), and a pop. of 10,000. The monastery of San Yuste, to which Charles V. retired after his abdication, lies 24 miles to the east of Plasencia.

Plasma, a rare siliceous mineral, a variety of quartz or chalcedony, of a dark-green colour, black when unpolished and seen by reflected light, but sub-translucent when held between the eye and the light. It is very nearly allied to heliotrope or bloodstone. The name is also used in biology for the simplest form of organised matter in vegetable and animal bodies, out of which the tissues are formed, especially of the blood-plasma (see BLOOD). —*Plasmon* is the name given to a food powder prepared from separated milk.

Plasmodia. See CELL, MYXOMYCETES.

Plassey (*Palasi*), a battlefield on the Bhágrathi River, 96 miles N. of Calcutta. The river has now eaten away the scene of the struggle. Plassey is celebrated in the history of India for the great victory gained by Clive over Suraj ud Dowlah, subahdar of Bengal, 23d June 1757, a victory which really laid the foundation of British supremacy in India. See CLIVE.

Plaster. See CAST, GYPSUM, BUILDING.

Plastering, the art of covering the internal faces of walls, the partitions, and the ceilings of a house or other building with plaster. It is difficult to get plaster to keep completely dry on the inside faces of external walls unless they are first covered with lathing (narrow strips of wood, see LATH). Ceilings and wooden partitions are always lathed so as to hold or key the plaster. Plastering is sometimes done in two, but most usually in three coats. The first or foundation coat is formed of lime and sand (mortar) mixed with hair. This is called *pricking* if done upon lath, and *rendering* if it is spread on a bare brick or stone wall. It is crossed with deep incised lines to key the second coat, which consists of fine lime mixed with some coarse plaster of Paris (see GYPSUM) floated on. The first coat should be completely dry before the second is added, but the latter is generally still a little damp when the third coat or *set* is put on. This last coat is usually composed of a mixture of fine lime, plaster of Paris, and a little size, and

is worked so as to produce a very smooth surface. The implements used by the plasterer are chiefly trowels and floating tools, with running moulds for mouldings. Ceiling ornaments and other enrichments are formed of plaster of Paris cast in moulds. Mouldings are run in the same material.

Plaster of Paris. See GYPSUM, CEMENTS.

Plasters are a class of medicinal agents consisting of 'adhesive substances, spread upon leather or cloth, so as to stick to the part of the body to which they are applied.' The plasters of the British Pharmacopœia owe their adhesiveness either to a combination of oxide of lead with fatty acids, or to the presence of a tenacious resin, or to both. The most important are lead plaster, or diachylon, which enters into the composition of many of the others; resin and pitch plasters; belladonna plaster; mercury plaster; menthol plaster; soap plaster; and cantharides or blistering plaster. Some of the most tenaciously adhesive of plasters (not in the Pharmacopœia) are made with preparations of india-rubber. Court or sticking plaster, for dressing slight wounds, consists of a thin layer of isinglass spread upon silk, and differs from the others mentioned in requiring to be softened with warm water before it will adhere. They are employed with two distinct aims—viz. to act *mechanically*, as by affording artificial support to weak muscular structures, by preventing movement of injured or inflamed parts, as in fracture of ribs, sprain of the ankle, &c.; and to act *medicinally* as counter-irritant, stimulant, anodyne, &c.

Plastilina. See CLAY.

Plata, LA. See ARGENTINE REPUBLIC, LA PLATA, LA PLATA (RIO DE).

Platea (Gr. *Plataiai*), a city in the western part of Bœotia, on the borders of Attica, and at the foot of Mount Citharon, 6 miles from Thebes. In 480 B.C. it was destroyed by the Persians, because the inhabitants had taken part with Athens in the battle of Marathon; but in the following year it was the scene of the glorious victory won by the Lacedæmonian Greeks, under Pausanias and Aristides, over the Persian hordes commanded by Mardonius. In the third year of the Peloponnesian war (429) it was attacked by a Theban-Lacedæmonian force, and heroically defended itself for more than two years, until it was starved into surrender; the little garrison of about 200 men were put to the sword, and the city was razed to the ground. Such of the Plataeans as escaped were hospitably received at Athens. By the treaty of Antalcidas (387) their children were allowed to go back again, and rebuild their city, after an exile of forty years; but they were again driven out by their implacable enemies the Thebans; and half a century elapsed before the victory of Philip of Macedon at Charonea enabled the Plataeans to return finally to their homes. After this the city was inhabited till the 6th century A.D.

Platanus. See PLANE.

Plateaus. See TABLELANDS.

Plate-marks. See HALL-MARKS.

Plate-powder, a composition of Ronge (q.v.) and prepared chalk used for cleaning gold and silver plate and plated articles. A gray plate-powder is also sometimes made by levigating quicksilver with twelve times its weight of prepared chalk; it puts a remarkable brilliancy on silver-plate, but is very injurious to it.

Plating signifies the covering of an inferior metal with one of the precious metals, the object being to give the appearance of silver or gold to articles chiefly intended for table use. Previous to the introduction of electro-plating (see ELECTRO-

METALLURGY) the method generally pursued was *Sheffield-plating*—by means of a plating furnace—soldering on to one or both sides of an ingot of the baser metal a thin plate of silver. See also TIN-PLATE, GALVANISED IRON.

Platinotype. See PHOTOGRAPHY.

Platinum (sym. Pt; atom. number 78; atom. wt. 194.8; sp. gr. 21.48 to 21.50) is one of the 'noble metals.' It is found only in the native state, usually occurring in small glistening granules of a steel-gray colour, which always contain, along with some gold, copper, iron, and sand, an admixture, in varying proportions, of several metals—iridium, rhodium, palladium, osmium, ruthenium—most of which are rarely found except in association with platinum. Sometimes, however, it is found in masses of the size of a pigeon's egg, and pieces weighing ten or even twenty pounds have occasionally been found. It was originally got in the Spanish gold-mines of Darien, but is now chiefly obtained from the Ural Mountains, though it has also been found in Brazil, Colombia, San Domingo, California, Oregon, Canada, Borneo, and the Transvaal.

There are two modes of obtaining platinum in the form of ingots from the crude native metal, both of which require notice. The earlier method—Cocks's, usually attributed to Wollaston (c. 1800–28)—was to precipitate a solution in *aqua regia* by a solution of sal ammoniac; the precipitate on incineration gave spongy platinum, which was pressed into form and hammered hot, so as to form an ingot, which it happens to be able to do, since platinum welds like wrought-iron when not too highly polished.

Deville and Debray's method is first to form a fusible alloy of this metal with lead, by exposing the platinum ore—2 cwt. being used in a single experiment, with equal weights of galena and litharge gradually added, and a little glass to act as a flux—to full redness in a reverberatory furnace lined with clay. The sulphur of the galena is oxidised and expelled, and the liquid alloy of lead and platinum is allowed to rest for some time, to allow the osmide of iridium, which is not affected by the preceding operations, to sink to the bottom. The upper portions of the alloy are then decanted, and cast into ingot-moulds, which are submitted to cupellation: and the metallic platinum which is left after the cupellation is melted and refined in a furnace of lime—which is employed in consequence of its being a very bad conductor of heat—by means of the oxyhydrogen blowpipe. The platinum obtained in this manner is nearly pure, and very ductile and malleable.

Platinum exhibits a bluish-white metallic lustre; it is exceedingly malleable and ductile, and is very infusible, melting only before the oxyhydrogen blowpipe, or in a very powerful blast-furnace, such as that used by Deville and Debray (fusing-point, 1779° C.). It expands less by heat than any other metal, and it is the heaviest form of matter known, with the exception of iridium (sp. gr. = 22.42) and osmium (22.48). It is unaffected by atmospheric action, and does not undergo oxidation in the air at even the highest temperatures. It is not acted on by nitric, hydrochloric, sulphuric, or hydrofluoric acid, or, in short, by any single acid; but in *aqua regia* it slowly dissolves, and forms a soluble tetrachloride. In consequence of its power of resisting the action of acids it is of great service in experimental and manufacturing chemical processes, platinum spatulas, capsules, crucibles, &c. being employed in every laboratory. Platinum is, however, corroded if heated with the alkalis or alkaline earths, and especially with a mixture of nitrate of potash and hydrated potash, an oxide

being formed which combines with the alkaline bases. In consequence of its infusibility and its non-oxidisability by atmospheric action, it is in great demand for electrical as well as for chemical apparatus. The introduction of platinotype processes in Photography (q.v.) caused such a run upon platinum that its price rose from about 35s. per oz. in 1880 to 80s. in 1890.

The form of the metal known as *spongy platinum* has been already noticed. The metal may, however, be obtained in a state of subdivision much finer than that in which it is left on heating the double chloride of platinum and ammonium—viz. in the state known as *Platinum Black*. In this form it resembles soot. It may be prepared in various ways, of which one of the simplest is to boil a solution of tetrachloride of platinum, to which an excess of carbonate of soda and a quantity of sugar have been added, until the precipitate formed after a little time becomes perfectly black, and the supernatant liquid colourless. The black powder is then collected on a filter, washed, and dried by a gentle heat. In its finely comminuted state, either as spongy platinum or platinum black, it possesses a remarkable power of condensing and absorbing gases, one volume of platinum black being able to absorb more than 100 volumes of oxygen. This absorption appears to be accompanied by a conversion of some or all of the oxygen into the modification known as Ozone (q.v.), since the metal becomes capable of exerting the most energetic oxidising action, even at ordinary temperatures. For example, it can kindle a jet of hydrogen, can oxidise sulphurous acid into sulphuric acid, ammonia into nitric acid, and alcohol into acetic acid, the rise of temperature in the last case being often sufficiently great to cause inflammation. Platinum in the compact form, as foil or wire, possesses similar powers, but in a far lower degree.

Platinum may be easily alloyed with most of the metals, the alloys being in general much more fusible than pure platinum. Hence care must be taken not to heat the oxides of metals of easy reduction, such as lead and bismuth, in platinum crucibles, as, if any reduction took place, the crucible would be destroyed by the fusion of the resulting alloy. An alloy of platinum, iridium, and rhodium is found, by the investigations of Deville and Debray, to be harder and capable of resisting a higher temperature than the pure metal, and hence is admirably adapted for the formation of crucibles, &c.; but it is not now in the market.

There are two oxides of platinum, a platinumous PtO , and a platinumic PtO_2 . The *sulphides* and *chlorides* correspond in number and composition to the oxides. Of these compounds the tetrachloride, $PtCl_4$, alone requires notice. It is formed by dissolving platinum in *aqua regia*, and evaporating the solution to dryness; and it is obtained as a deliquescent, reddish-brown mass, which forms an orange-coloured solution in water, from which, on evaporation, it crystallises in prisms. It is also freely soluble in alcohol and ether. A solution of this salt is much used for the recognition and determination of potash and ammonia.

Plato, the great Athenian philosopher, was born during the early years of the Peloponnesian war, most probably in 427 B.C. Diogenes Laertius (q.v.), in his gossiping *Lives of the Philosophers*, and other writers of the Christian era have handed down a considerable amount of detail respecting his life, but most of it is of very doubtful value. As time went on, legends gathered round a famous name; and many of the authorities used by Diogenes were in all probability, like Diogenes himself, almost entirely wanting in critical capacity. According to one account Plato was born in Athens itself, according to another in

the island of Ægina. He came of an aristocratic family, his father Ariston boasting descent from Codrus the last king of Athens, who was said to be descended from the god Poseidon: whilst the family of his mother, Perictione, claimed kinship with Solon, and through Solon with Neleus, a son of Poseidon. Even this double claim to superhuman ancestry was not sufficient for the admirers of the 'divine' Plato. Diogenes tells us on the alleged authority of (among others) Speusippus, Plato's own nephew and successor in the academy, that the story was current at Athens that his real father was Apollo, and that the god appeared in a vision to Ariston, who thereupon kept away from his wife till her child was born. Plato's birthday was celebrated on the same day (at the end of May) as that of Apollo himself. Bees from Hymettus are said to have fed the infant with their honey. Plato was originally named after his grandfather, Aristocles: but his gymnastic teacher is said to have called him 'Platôn,' because of his broad shoulders, though others say he got this name from the breadth of his forehead. There is a story that he wrestled at the Isthmian games. He cannot well have escaped military service during the terrible struggle of Athens in the last years of the Peloponnesian war. In youth he is said to have written poetry, and this we can easily believe: a few epigrams in the 'Anthology' are ascribed to him. With regard to his philosophical education we have the important testimony of Aristotle (*Metaph.* i. 6), that from his youth he had been familiar with Cratylus, a follower of Heraclitus, and that the other philosophic influences under which he came were those of Socrates and of the 'Italic' schools—i.e. Pythagoreans and Eleatics. Critias (afterwards one of the 'Thirty Tyrants') and Charmides were both maternal relatives of Plato, and both belonged to the Socratic circle. Possibly it was through them that Plato came under the decisive influence of Socrates. If Plato was, as Diogenes says, twenty years old when he first became companion of Socrates, his discipleship lasted for eight years. According to his own account in the *Phædo*, Plato was prevented by illness from being present at the last conversation and death of his master (399 B.C.).

Plato made no attempt to enter on a political career. Through family ties he was connected with the anti-democratic party, who admired Sparta. His youth was passed amid the disasters and failures of the Athenian democracy; and the martyrdom of the teacher who had inspired him would not tend to increase his sympathy with that form of government. After the death of Socrates he seems to have stayed some time at Megara, where Euclides, who had been one of the Socratic circle but belonged also to the Eleatic school, had established himself. Euclides developed the Eleatic philosophy in the direction which Zeno ('the father of logic') had begun—he was chiefly occupied with what, after Aristotle's time, came to be considered logical questions. His school was known as the 'Dialectical' or 'Eristic'—i.e. 'disputations.' This sojourn at Megara was doubtless an important stage in the development of Plato's thought. How long he stayed at Megara we do not know; nor can we tell with certainty whether he was back at Athens in 394 (he is said to have taken part in a Corinthian campaign), or whether he did not return to Athens till ten or twelve years after the death of Socrates. During this period of his life he is said to have undertaken extensive travels—to have visited Cyrene, Egypt, Italy, and Sicily. The visit to Sicily is almost certain; visits to the Magi and the Persians, the Babylonians, and the Hebrews are undoubtedly fictions of a later age, which supposed that wisdom could only come out

of the East. The despotism of the elder Dionysius in Syracuse probably helped to suggest the pictures of the tyrant in the *Republic* and *Gorgias*. On his way back from Sicily Plato is said to have been seized by order of Dionysius and sold as a slave in Ægina, but to have been ransomed by a certain Anniceris of Cyrene. The return to Athens has been variously assigned to the years 389 and 387. Plato now began to teach in the Academy (q.v.), a place of exercise in the western suburb of Athens, planted like a grove, and named from the hero Acadēmus. There and in his own garden, which was adjacent, he gathered round him a band of disciples, teaching them probably, like his master Socrates, mainly by conversations, and embodying the results of his thinking and teaching in his written *Dialogues*. Two more visits to Sicily interrupted the quiet of these later years. Soon after the death of the elder Dionysius (368) his friend Dion summoned him to come to Syracuse, in the hope that he might convert the younger Dionysius to philosophy, and so realise the dream of a philosopher-king. The young despot welcomed him warmly, but soon became weary of serious discussions, quarrelled with Dion, and banished him; and Plato had to give up his fruitless task. A third journey to Sicily (about 361) was undertaken in the vain attempt to reconcile Dionysius to Dion. Plato's own life, it is said, was only saved from the tyrant by the intercession of the Pythagorean Archytas. On his return to Athens (360) he again resumed his teaching and writing, till, after a peaceful old age, he died 'in his eighty-first year' at a wedding-feast (347). He was succeeded in the Academy by his sister's son, Speusippus; but his greatest disciple was Aristotle, who must have come under his influence after the return from the second Sicilian voyage.

Of Plato's philosophical writings none apparently have been lost; but along with undoubtedly genuine works there have come down to us others whose authenticity is open to question. Thrasyllus, a scholar of the time of Augustus and Tiberius, considered thirty-six of the works ascribed to Plato to be genuine, rejecting a few quite unimportant writings as spurious. This 'canon of Thrasyllus' probably represents the tradition of the Alexandrian library. Aristophanes, one of the Alexandrian librarians (about 264 B.C.), had arranged several of Plato's dialogues in 'trilogies' (groups of three), following the analogy of Attic dramas. Plato himself suggests at least two such trilogies—viz. *Republic*, *Timæus*, *Critias* (unfinished); *Sophist*, *Statesman*, *Philosopher* (never written). Thrasyllus adopted an arrangement in tetralogies, making nine groups of four, only one of which groups (viz. *Euthyphro*, *Apology*, *Crito*, *Phædo*), which give a connected picture of the trial, last days, and death of Socrates) is anything but extremely artificial. Grote accepts all the works in the 'canon of Thrasyllus,' believing that the Alexandrian library had every means of obtaining a genuine collection of Plato's writings from his successors in the Academy; but almost all other modern scholars reject the *Epistles*, some of which may, however, be very early forgeries. And the authenticity of some ten or more of the dialogues has been very much disputed. Fortunately, the more important works are the least open to question. We have Aristotle's statement that the *Lives* were written by Plato after the *Republic*. Beyond that we can only conjecture the order in which the dialogues were written; and the hypotheses of different scholars have varied greatly. We may safely put aside the theory of Schleiermacher (with whom the modern critical study of Plato begins), that Plato quite early in life had formed a complete system of philosophy in his mind, and that

the dialogues were published by him in an order intended to unfold this system gradually to the world. It would be more true to say that Plato never had any completely formed system, and during a long life of speculation his opinions must have undergone modification. We cannot, indeed, with complete certainty arrange his dialogues in a series representing exactly his mental development (as K. F. Hermann and others have attempted); but the student may most profitably consider them in groups, suggested by the different influences that acted on him, and especially by his changing attitude towards the teaching of Socrates. First of all would come those short dialogues in which, so far as we can judge by comparing him with Xenophon, Plato does not go beyond what the actual Socrates might have said. Such are the dialogues which deal with some particular virtue; thus, in the *Charmides* Socrates questions the beautiful and modest youth Charmides as to what the virtue of modesty or 'temperance' is. In the *Laches* he questions the soldier Laches about courage. The most important of this group is the *Protagoras*, in which Socrates argues against this famous sophist that all virtue is one, and that it is identical with knowledge. Some of these slighter dialogues may have been composed before the death of Socrates; Diogenes Laertius tells us that Socrates on hearing Plato read the *Lysis* (which deals with friendship) said: 'O Hercules! what a lot of lies the young fellow has told about me.' Ancient tradition made the *Phaedrus* the earliest dialogue; but this almost certainly belongs to a later period, though earlier than the *Republic*. The *Apology*, or 'Defence of Socrates on his Trial,' has probably more historical accuracy than any other composition of Plato's (Plato tells us he was present at the trial), and may have been written soon after the death of Socrates. The *Euthyphro* (concerning piety) and the *Crito* (Socrates in prison) may belong to the same period. The *Phaedo*, however (the last conversation of Socrates, on the immortality of the soul), is probably of later date, as it implies the theory of ideas, and may be assigned to a time after Plato's visit to Sicily—i.e. after he had come more strongly under Pythagorean influences. Some modern scholars, laying great stress on the 'Megarian' influence, assign the great metaphysical dialogues (*Parmenides*, *Theaetetus*, *Sophist*, *Statesman*) to the time between 399 and 386, when Plato began his teaching at the Academy. Others, with more probability, consider these dialogues and the *Philebus* to belong to a later period than the *Republic*, and this opinion is gaining ground. The *Phaedrus*, *Symposium* ('Banquet'), *Gorgias*, *Republic*, *Phaedo*, in which (along with the *Theaetetus*) Plato's literary skill is at its very highest, may perhaps be all assigned to the period of his life after forty, but before his old age. In these dialogues the personal characteristics ascribed to Socrates are probably represented with historical and, at least, with dramatic truth; but theories are introduced which betray strong Pythagorean influences. We must of course remember that while Plato idealises Socrates, and makes him more of a metaphysician than in all probability he was, Xenophon, who has a very unphilosophical mind, most certainly understates him, and makes him more of a commonplace moralist than he must have been in order to stimulate Greek thought as he did. In the *Timaeus* Plato would have felt it inappropriate to make Socrates the exponent of theories about the physical universe, and after a short introductory conversation the dialogue form is deserted, and Timaeus, a Pythagorean, expounds the cosmogony of his school. In the *Sophist* and *Statesman* 'an Eleatic stranger' is the chief speaker; in the

Parmenides the youthful Socrates is criticised by the great Eleatic philosopher. In the *Laws* Socrates does not appear at all, the leading speaker being 'an Athenian stranger' (Plato himself?). May we not regard this as an indication that in his later years Plato felt himself farther away from his master? These later dialogues, in fact, seem like a transition from the Plato of the *Phaedrus* and of the *Republic* to Aristotle.

It is customary to treat of Plato's philosophy under the three heads of dialectic (or logic), physics, and ethics. But, it must be remembered, these divisions did not exist for Plato himself, nor, in fact, had he, strictly speaking, a 'system' of philosophy. Plato's philosophy may most correctly be regarded as a development of the teaching of Socrates, but containing elements derived from the earlier philosophies from which Socrates had purposely turned away. Aristotle's philosophy is, however, a development of Plato's; and we, knowing what becomes of Plato's suggestions in the hands of his pupil, are able and apt to see a greater amount of system than Plato himself would have recognised.

The dialogue was to Plato much more than a mere literary form into which he chose to fit his thoughts. The 'conversations of Socrates' gave to Plato his conception of the method of philosophy. 'Dialectic' comes from a word which means 'to converse,' 'to discuss,' and it is significant that Athenian philosophy originated not in the meditations of the solitary recluse, but in the discussions of a city of talkers. It is said that Zeno the Eleatic used the dialogue for philosophical writing before Plato, but this is very doubtful. In many of the later dialogues the chief speaker has so much of the talking to himself that the dialogue becomes a rather empty form, and is evidently yielding place to the lecture as the vehicle of philosophical exposition.

According to a well-known sentence of Aristotle, the germs of logical doctrine which may be ascribed to Socrates are 'the inductive method' and the endeavour to get 'general definitions.' When people spoke about persons or acts as just or beautiful, Socrates would insist on asking 'What is justice?' 'What is beauty?' and would test every definition brought forward by applying it to particular instances, content to remove error even where complete truth could not be obtained. This is the procedure of Plato in the earlier dialogues. In the *Theaetetus*, however, the Platonic Socrates asks the profounder question, 'What is knowledge?—i.e. true or scientific knowledge. It is not 'sensation' (or 'perception'), as Protagoras and his followers suggest: sensation alone gives us no objective certainty, valid for every one. Nor is it 'opinion.' Opinion may be true, but has no certainty. A man only 'knows' when he has got at the reasons or causes of things, when he sees facts not in an isolated way, but connected by the 'chain of causation' (*Meno*); he must be dealing with what is permanent and universal. What then is this? Plato's answer comes to be found in the theory of 'Ideas.' (The word means properly 'forms' or 'shapes,' and so 'kinds.' The analogy of sculpture may help one to understand how the Greeks came to regard 'the form,' in contrast to the 'material,' as the essential element.) This theory, following Aristotle's guidance, we may consider a development of the Socratic 'universal conception,' and also of the Pythagorean doctrine of 'numbers.' By this theory Plato seeks to reconcile the opposing views of the Heracliteans and of the Eleatics (q.v.). According to Plato, both the one, the permanent, and the manifold, the changing, have their place in the universe, the former in the world of ideas, the

intelligible world, with which 'science' deals, the latter in the world of sense, with which mere 'opinion' is content. In the *Republic* Plato elaborates this theory of knowledge, and gives a symbolical representation of it in the famous image or 'myth' of 'the Cave.' The majority of mankind are pictured by him as prisoners in a subterranean cavern, chained with their backs to a fire, looking at the shadows thrown by it on the rocky wall and mistaking them for realities. The turning round of some of these prisoners to the light, and the toilsome ascent up the steep slope to the mouth of the cave, and the gradual training of their eyes bewildered in the sunlight to see the real things in the upper world, and finally to look up to the sun itself—this represents the education of the philosopher. Education is 'a turning round of the eye of the soul.' Learning, according to the more startling language of the *Meno* and *Phaedrus*, is 'recollection': the soul in a previous existence has beheld the 'ideas,' and knowledge is possible just because the mind does not acquire something alien to it, but recovers what is its own. The way from the life of the senses and of mere vague opinion to the highest or philosophical knowledge is through the mathematical sciences. Mathematics, being the only science which had then outgrown the merest infancy, is to the Greeks the type of science in general. (Plato is said to have had the words 'Let no one ignorant of geometry enter' inscribed on the door of his school.) In the conceptions of mathematics we have a clue to the understanding of Plato's theory of ideas. The geometriician looks at a particular triangle, but he speaks not of *this*, but of the triangle. The triangles we see are triangles only by 'participating in' ('imitating,' the Pythagoreans would have said) the triangle. And it remains true for us still that we can only scientifically know anything in so far as we can find in it a universal element, which manifests itself or 'is present' (in Platonic language) in the particular. The botanist, for example, knows a particular plant only as a specimen of a *species* (the Latin equivalent of Plato's 'idea'). But the philosopher must not remain in the region of the various special sciences: he has the passion for unity and universality. Plato has a vision of the true science which is above all particular sciences, and is the unity and 'coping-stone' of them all: and this he calls in a special sense 'dialectic,' which does not like mathematical thinking need the help of sensible images, but deals with 'ideas' alone in their relation to one another and to the highest of all, 'the idea of the good.' These ideas are not mere concepts of our minds: they are, in Plato's phrase, 'the most real existences.' The extreme form of mediæval 'Realism,' according to which universals are prior to and more real than particular things, is a crude version of Plato's doctrine. It is indeed an adaptation of Platonic philosophy to Christian theology, for which Plato gives no sanction, if the ideas are called 'the thoughts of God'; but the phrase is perhaps less misleading than many others which have been used about them. Plato does speak (in *Republic*, x.) of God having 'made' the ideas, as a human artificer makes things in imitation of them; but he is there talking in pictorial language. God in Plato's system is rather the 'idea of the good,' the good-in-itself, which is the cause alike of knowing and of being, as the sun in the visible world is the cause both of light and of life. In the *Timæus* the world is said to be fashioned by the Creator or Artificer after the pattern of the ideas; but here also the language is figurative. Plato's 'ideas' must, however, be thought of both as 'real kinds' and as archetypes. Plato's presentation of his theory varies: most probably the theory itself underwent modification. In the

Parmenides some of the objections made to it are the same as were afterwards urged by Aristotle—a remarkable instance of a philosopher criticising himself.

The relation of the hierarchy of the ideas to the supreme idea of the good is nowhere worked out by Plato. Dialectic remains only an ideal science. The true dialectician is he who will see things in their unity (compare Herbert Spencer's definition of philosophy as 'completely unified knowledge'): he will also 'divide things rightly according to their kinds.' The method of philosophy is a bringing together and a dividing (*synagōgē* and *diáiresis*). In this we may recognise the germ of Aristotle's 'induction and deduction.'

The *Timæus* is the one work which Plato has devoted to the philosophy of nature; and though it has exercised directly and indirectly an enormous influence over the ancient and mediæval world, as it has specially attracted mystical and theosophical commentators, in Plato's own view it occupies a very subordinate position. We are again and again warned by him not to expect strict truth, but only approximations and figurative statements ('myths') in dealing with such subjects. The notion of 'emanations,' which plays so great a part in later philosophy is latent in the *Timæus*. The *Cosmos*, or order of the universe, is the 'one only-begotten' image of God, its father and creator (*Demiourgos*—i.e. 'artificer'). The Creator was good, and wished to make the world as like himself as possible; but no created or visible thing can be perfect. The material out of which the orderly world is made introduces imperfection into it. (This conception of matter as evil had a potent influence in later times, especially when combined with Oriental ideas—e.g. in Gnosticism, q.v.) So, too, the eternal Creator could not make the world eternal like himself, and in making it made Time, 'the moving image of eternity.' To the obscure details of Plato's cosmology and physics it would be unprofitable to refer here. Cosmology is again introduced, but briefly, and with similar warnings that it is to be treated as mythical, in connection with the immortality of the soul in the *Phædo* and *Republic*. The soul of man (like the 'soul of the universe') is intermediate between the ideas and the corporeal. The human soul, as it exists in the body, has three parts or elements: (1) the rational; (2) the spirited element; (3) the appetitive. The rational element alone, which is the soul in its true being as it is apart from mixture with body, is properly immortal. The doctrine of immortality (i.e. the pre-existence of the soul as well as its existence after death) is introduced in the *Phædrus*, *Republic*, and *Phædo*, and is the main subject of the third. In all Plato makes use of the Pythagorean notion of transmigration. What he says must be taken as largely mythical and figurative. His whole philosophical thinking implies the eternity of Reason, but how far he believed in what is now understood by personal immortality has been and may be doubted. Wordsworth's famous *Ode on Immortality* is generally considered 'Platonic'; but it turns on a misapplication of Plato's doctrine of 'recollection.' Plato would certainly not hold that the new-born infant is nearer perfection than the aged philosopher.

Plato is so far true to the example of Socrates that, though he has metaphysical interests which were alien to his master, yet the practical interest always predominates. Philosophy is to him not mere intellectual speculation, but a habit of mind and a manner of living. As we have seen, the highest of the ideas is 'the good.' He cannot accept the Cyrenaic view that pleasure is the good; but neither does he agree with the Cynics that all pleasure is evil. Pleasures are good or bad, high

or low, according to the part of the soul to which they belong. Socrates had identified virtue and knowledge, had asserted that virtue was one, and that virtue could be taught. All these doctrines Plato accepted; but modifications gradually appear. In the *Republic*, the dialogue in which all the various elements of his philosophy are united more than in any other, Plato accepts without proof the popular distinction of four 'cardinal virtues' (as they afterwards came to be called), and fits them in with his psychology. Wisdom is the virtue of the reason, Courage of the spirited element, Temperance (i.e. Moderation, Self-control in general) is the virtue of the lower parts in their relation to the higher, while Justice ('Righteousness' would perhaps be a better word) is not the virtue of any special part, but of the whole soul, and is defined as 'every part doing its own work and not interfering with the others.' To arrive at the nature of Justice (the professed object of the discussion) the Platonic Socrates has turned 'from the small to the large letters'—i.e. from the individual to the state, where human nature can be seen 'write large.' Wisdom is the virtue of the rulers, Courage of the warriors, Temperance or Moderation is the harmony resulting from the obedience of the lower to the higher, and Justice is the virtue of the whole state. A perfect state would require a special ruling caste, and the only true rulers in Plato's opinion are philosophers. Plato allows that there may be ordinary virtues resulting from custom or right opinion (cf. *Meno* and *Phaedo*), but the highest type of conduct must be bound up with the highest type of knowledge. Those alone who have the philosophic nature (which is sometimes described by him as the passionate love of truth) are the proper rulers in a perfect state, and in the philosophic nature all virtues are united. In this ideal commonwealth (the parent of so many 'Utopias'), besides the paradox of the philosopher-king, the other paradoxes by which Plato startled his contemporaries were (1) that men and women should have the same education and the same pursuits, and (2) that private property and the family should be abolished. All things were to be in common; and the breeding and rearing of the citizens was to be entirely under the control of the philosopher-rulers. Just as in his theory of knowledge Plato's ideal is unity, so his political ideal is that the state should be as much as possible one, one as a family is one, or rather as one individual is. All are to be 'members of one body.' Some of the features in Plato's ideal state were doubtless suggested to him by the Pythagorean brotherhoods, many of them by the actual institutions of Sparta. In fact, Plato's ideal state might be described as a combination of philosophy with Spartan military discipline. Without the philosophy we have an inferior form—the Spartan state, or 'timocracy,' in which not philosophy but military honour is the ruling principle. Inferior to that comes oligarchy, of which the ruling principle is *wealth*. Lower still is democracy, the *equality* of good and bad alike; and worst of all is tyranny, the rule of the 'wild-beast element in man.' In the *Statesman* Plato gives a rather different classification of constitutions, recognising both a better and a worse form of democracy, and placing both below aristocracy, but above oligarchy: in the true state the number of the rulers matters not, if only they have 'the science of ruling.' In the *Laws* he elaborates a second-best state, giving up communism as too difficult of attainment, and proposing a complete equalisation of property. In the *Laws* also he praises 'mixed government.'

In the earlier part of the *Republic* Plato discusses the place of art in education. Homer and

Hesiod were the Greek 'Bible'; but Plato objects to much in the poets and in the popular religion as false and immoral. Music and poetry should be simple (here again the complex, the manifold, is of the nature of evil), and should imitate only what is good, hence dramatic art is especially objected to. Towards the end of the dialogue he goes further, and objects to all 'imitation,' whether in painting or in words, as being only a copy of the so-called real things, which are themselves only a copy of the true reality—the ideas: and so he drives the poets from his ideal state. Aristotle's *Poetics* may be regarded as in part a 'Defence of Poesy' against Plato's criticism. Why, it has often been asked, has Plato, himself so great an artist, dealt so Puritanically and so unsympathetically with art? Partly, perhaps, because the first steps in reflection about art, as about religion, imply a certain withdrawal from the sway of that which is to be criticised and understood. But the *Republic* gives only one side of Plato's thought on art. In the *Symposium* (in which the banqueters praise Love in turn) and in the *Phaedrus* 'the beautiful' occupies the same place that 'the good' does in the *Republic*. Plato is after all a true Athenian, and thinks of the good under the form of the beautiful. ('Beautiful-and-good' is the Greek equivalent of 'noble' or 'gentleman' in its best sense.) 'All that is good is beautiful,' he says in the *Timæus*. The true lover is akin to the philosopher, and loves the beauty of the soul rather than the beauty of the body, and ascends from the love of the many beautiful to the love of absolute beauty. There is indeed a strain of asceticism in Plato's view of life; but there is none of the Cynic contempt for the beauty of the human form and for the graces of social intercourse. In the *Phaedo* Socrates speaks of the body as 'the prison-house of the soul,' and of philosophy as 'the practising of death.' But Socrates at the banquet speaks somewhat differently from Socrates awaiting his end: and in the *Republic* the body has to be carefully trained that it may be a fit servant of the soul, and the young are to grow up amid fair sights and sounds.

Plato's influence on human thought has been even more widely diffused, but is more difficult to measure than that of Aristotle. The various schools of the Old, Middle, and New Academy caught only a small portion of his spirit. The Stoics, especially the later Stoics, borrowed much from him. Perhaps no school of Greek philosophy was unaffected by him. In Alexandria Jewish thinkers fell under his fascination (see PHILO); and Christian theology is largely Platonic. But the Alexandrian Platonists and the Neoplatonists (see NEOPLATONISM) differ from Plato himself in making the *Timæus* the centre of his system. The writings ascribed to Hermes Trismegistus and Dionysius the Areopagite belong to the Neoplatonic period. The latter was translated by Eriugena in the 9th century, and Platonism reached the western world in the middle ages through the medium of those mystical writers. The Italian Renaissance and the revolt against Scholastic Aristotelianism revived the study of Plato's own writings; but the enthusiasm for Plato in the 15th century at Florence and the less important 'Cambridge Platonism' of the 17th century were both after the Neoplatonic manner, and, like the medieval 'Aristotelianism,' brought more veneration than understanding to the interpretation of the philosopher. Of all Plato's disciples (to adapt a famous saying) perhaps only one had understood him—Aristotle—and he did not. His criticisms are often strangely unsympathetic. Yet Aristotle's whole system gives a more trustworthily clue to Plato's real philosophical significance than is to be

got from mystical interpreters whose zeal was not always according to knowledge (see ARISTOTLE).

The first printed edition of the Greek text of Plato is the Aldine (Venice, 1513). Plato is constantly cited according to the pages of the edition printed by H. Stephanus (Paris, 1578). There are editions by Stallbaum, Baier, Orelli and Winkelman; K. F. Hermann, Schanz, and Burnet (works, 5 vols. 1900-8; *Phædo*, 1911; *Euthyphro*, *Apology*, *Crito*, 1924). Plato was first printed in Latin translation by Ficino (Flor. 1483), which was the best outcome of the Platonic revival, and is the basis of the ordinary Latin versions. A complete English translation was published by Thomas Taylor, 'the Platonist'—i.e. Neoplatonist, in 1804 (including nine dialogues translated by Sydenham about 1759). The poet Shelley translated the *Symposium* (included along with other fragments of Platonic translations in Buxton Forman's edition of his *Works*). Jowett made Plato an English classic (*Trans. with Introductions*, 3d ed. 1892; reissued 1925). In the 'Loeb Library' is an edition with translation by various scholars. There are many translations of separate dialogues. Among works on Plato's philosophy may be named Grote's *Plato*; Whewell's *Platonic Dialogues* (1860); Zeller's *Plato*; Pater's *Plato and Platonism* (1893); T. B. Strong's *Platonism* (1896); Russell's *The School of Plato* (1896); Gomperz's *Greek Thinkers* (trans. 1901-5); J. A. Stewart's *The Myths of Plato* (1905) and *Plato's Doctrine of Ideas* (1909); A. E. Taylor's *Plato* (1922), and *Platonism and its Influence* (1925); and the relevant sections in the *Histories of Philosophy* by Schwegler, Ueberweg, Erdmann, &c. Lutoslawski in *The Origin of Plato's Logic* (1897) rearranged the order of Plato's works on the ground of style alone, the doctrine of the ideas as objective existences being, he asserts, but a passing phase. Wilamowitz-Möllendorf's *Platon* (1919) is an important and valuable work in spite of defects. For the Cambridge Platonists, see the articles LATITUDINARIANS, CUDWORTH, MORE, SMITH (JOHN), WHITCHOTE.

Platoff, COUNT MATVEI IVANOVICH, was born at Azov, 17th August 1757. He served in the Turkish campaign of 1770-71, and in subsequent wars showed such capacity and courage that he was named by Alexander I. in 1801 Hetman of the Cossacks of the Don. As such he took part in the campaigns against the French, 1805-7, and, after the enemy had evacuated Moscow, hung upon their rear with pitiless pertinacity, wearing them out by incessant attacks, cutting off straggling parties, and capturing their convoys of provisions. He defeated Lefebvre at Altenburg, 28th May 1813. After the French disaster at Leipzig he harassed their retreat on French soil, gained a success at Laon, and made his name memorable by the devastations of his hordes of semi-savages. He was enthusiastically welcomed, and presented with a sword of honour on the occasion of his visit to London in company with Blücher. The tsar gave him the title of Count in 1812. After the war he retired to his own country, and died near Tcherkask, 15th January 1818.

Platonic Love, the love of soul for soul, a love into which sensual desire is supposed not to enter at all. See the last paragraph but one in the article PLATO.

Platt-Deutsch, or LOW GERMAN, the direct descendant of Old Saxon, is spoken to-day in different dialects by the peasantry of north Germany from the Rhine to Pomerania. It resembles Dutch, Flemish, Frisian, and English in the absence of the High German consonant-shift, and has simple grammatical rules. It is very appropriate in the mouths of the people who use it, their chief characteristics being naïveté, a childlike good-nature, and sturdy honesty; and it lends itself readily as a vehicle for fairy-tales, folk-tales, and simple folk-songs, such as those collected in *Firminich's Germaniens Volkerstimmen*. Klaus Groth (q.v.) and Fritz Reuter (q.v.) have given it a high literary standing.

See German works on Platt-deutsch literature by Krüger (1913) and Stammler (1920); Schön's *Geschichte der deutschen Mundartdichtung* (1921); also the articles GERMANY (*Language and Literature*), GRIMM'S LAW, EULENSPIEGEL, REYNARD THE FOX.

Platte, or NEBRASKA, an affluent of the Missouri River, is formed by the junction in west central Nebraska of the North and South Forks, which rise among the Rocky Mountains in Colorado, are respectively some 800 and 550 miles long, and are neither of them navigable. The general course of the Platte is eastward, in a wide shallow stream, over the treeless plains of Nebraska, till it reaches the Missouri after a winding course of about 450 miles. With its forks it drains some 300,000 sq. m., but like them it is not navigable.

Platten-See. See BALATON.

Plattsburg, capital of Clinton county, New York, on Lake Champlain, at the mouth of the river Saranac, 73 miles by rail S. of Montreal. It has manufactures of flour, lumber, iron, type-writers, sewing-machines. In Plattsburg Bay, on 11th September 1814, a British flotilla of sixteen vessels was defeated and partly captured by Commander Thomas Macdonough, with fourteen vessels; while a large land force, under Sir George Prevost, was repulsed by General Macomb, with 1500 men. Pop. 11,000.

Platypus. See ORNITHORHYNCHUS.

Plauen, in Vogtland, one of the most important manufacturing towns of Saxony, stands in the south-west corner, on the White Elster, 78 miles S. of Leipzig by rail. Its chief industries are the manufacture of muslin, gauze, tulle, curtains, lace, embroidery, textile machinery, and large bleaching and spinning works. Pop. (1890) 46,899; (1919) 104,918; (1925) 109,953.

Plautus, M. ACCIUS (or more correctly *T. Maccius*), the chief comic poet of Rome, and probably among his own countrymen the most popular Roman author of any age, was born about 250 B.C. at Sarsina, a village in Umbria, a district which must at this time have been thoroughly Latinised. We have no knowledge of his early life and education, but it is probable that he came into Rome while still young, and acquired there his complete mastery of the most idiomatic Latin. Though born in the country, he introduces countrymen chiefly as subjects for ridicule; he always writes as a townsman, familiar with city life, especially among freedmen, craftsmen, and the middle classes. At Rome he found employment in connection with the stage, of what kind precisely we do not know. In this position he saved money enough to enable him to leave Rome and start in business on his own account in the way of foreign trade; and such early thrift shows strong character and determination to rise in the world. His plays evince close familiarity with seafaring life and adventure, and an intimate knowledge of all the details of buying and selling and keeping accounts—experience probably acquired during this period. We know that he failed in business, and returned to Rome in such poverty that he had to earn his livelihood in the service of a baker by turning a hand-mill, work generally performed by slaves. At this time, shortly before the second Punic war broke out, he was probably about thirty years of age, and while in this humble occupation he composed three plays which he sold to the managers of the public games. The price paid him enabled him to leave the mill, and he spent the rest of his life at Rome. Probably he commenced to write about 224 B.C., and for forty years, until his death in 184, he continued to produce comedies with wonderful fecundity. Most of the plays we have belong to the last ten years of

his life. It is not certain whether Plautus ever obtained the Roman franchise. He was the contemporary of Nævius and of Ennius.

His plays appear not to have been published during his lifetime, but to have been left in the hands of the actors, who probably both interpolated and omitted passages to suit them for the stage. Almost all the prologues were written after his death. About 130 plays were attributed to him in the time of Gellius, who held most of them to be the work of earlier dramatists, revised and improved by Plautus. Roman critics considered most of them to be spurious. Varro in his treatise *Questiones Plautine* limited the genuine comedies to twenty-one; and these so-called 'Varronian comedies' are the same which we now possess, only one, the *Vidularia*, being lost. Plautus' plays were immensely popular on the stage, not only with the people, but with the educated classes, and were acted, as Arriobius tells us, in the time of Diocletian, five centuries later. Plautus borrowed his plots to a large extent from the New Attic Comedy, which dealt with social life to the exclusion of politics; he doubtless imitated its general types of character, but he 'adapted' very freely, and infused into his borrowed framework a new and robust life, which was Roman to the very core. His perfect spontaneity, vivacity, and vigour of language, and the comic power of his dialogues, show that these are the genuine fruit of his own genius. The scenes of his comedies are always laid in Athens or in some Greek town. Had he depicted the family life of Romans as so corrupt, the magistrates would no doubt have interfered; but the Greek personages of his plays speak and act in every respect like Romans; they refer familiarly to places in Italy, to streets, magistrates, and customs at Rome. Not even Shakespeare is more careless about inconsistency of this kind. It is probable that Plautus wrote with great rapidity; some of his finest comedies are spoilt through the action being too hurried towards the close. Roman comedy expressed 'a rebound from the severer duties of life.' Plautus' audience were in holiday mood, and did not expect to be admonished as to duty or entertained with serious reflection. His leading characters possess boundless animal spirits, infinite resource in difficulty, and but small conscience. His heroines show that, as Sellar says, Plautus was more familiar with the ways of 'libertine' than of Roman ladies. His favourite subject is a plot by which a slave, on behalf of his young master and the mistress of the latter, cheats a father or some one else. Plautus shows no feeling for nature, though he is fond of describing the sea in calm and storm; his lack of any sense of natural beauty and of high imagination makes a deep gulf between him and Aristophanes. Yet he shows distinct creative power, as in the character of Euclio the miser in the *Aulularia*, who, though entirely possessed by his one idea, is still honest and independent and not contemptible. Fine touches are not wanting. In the *Capitula* the slave Tyn-darus, cheerfully willing to sacrifice all for his young master, shows that Plautus had the power to conceive a really noble character. The charm of Plautus, lying in his genuine humour and powerful grasp of character, goes deep down to the roots of human nature; he delights his readers to-day as truly as when he made Roman theatres ring with applause, or when St Jerome solaced himself in his cell by reading the well-loved comedies. His joyous sense in all circumstances of the gladness of life is the sign of a strong and manly nature; he makes his reader look involuntarily at the bright side of things. According to Sellar, the five best plays are *Aulularia*, *Captivi*, *Menecmi*, *Pseudolus*, *Rudens*. Shakespeare has imitated the plot of the *Menecmi*,

entirely recasting it, in his *Comedy of Errors*. Molière's *L'Avare* is borrowed from the *Aulularia*. So probably Plautus utilised Greek comic authors.

English translations are by Thornton and Warner (1767-74), Riley (1880), Sugden (1895), Allison (five plays, 1914), Wright and Rogers (three plays, 1925), and Nixon (with text, 5 vols. 'Loeb Library,' 1916 *et seq.*). Ritschl showed great acuteness in restoring Plautus's text, which is very corrupt; see the edition by Goetz and Schoell (1893-94), and that of W. A. Lindsay (1903); Westaway, *The Original Element in Plautus* (1917); also Sellar's *Roman Poets of the Republic*.

Play. See ATHLETICS, and the articles on the several sports and games; also Groos, *The Play of Animals* (trans. 1898); *The Play of Man* (trans. 1902).—For stage plays, see DRAMA, THEATRE. A relic of the censorship of the press survives in Britain in the licensing of stage plays. By an Act of 1843 no plays may be acted for hire till they have been submitted to the Lord Chamberlain, who may refuse to license them in whole or in parts; the official who reads them for this purpose being the 'examiner of stage plays.' A penalty of £50 attaches to the offence of acting an unlicensed or prohibited play; and the theatre in which it is represented forfeits its licence. During the reign of Charles I. the censorship, which for three-quarters of a century had been entrusted to the Master of the Revels and others, was in the hands of the Lord Chamberlain. This arrangement, of course, came to an end with the closing of the theatres at the beginning of the Civil War. The censorship as it now exists owes its origin to Sir Robert Walpole, who acted from purely political motives. Fielding had produced his play *Pasquin* in 1736, and next year *The Historical Register*. In these he had exposed the corruption by means of which the government carried out its policy. Annoyed by this satire, Walpole had a bogus play of scurrilous character prepared, laid extracts from it before the House of Commons as the work of Fielding, and ended Fielding's dramatic career by procuring in this way the passing of the Licensing Act of 1737. Among other restrictions which it placed upon theatres, this act subjected all plays to the censorship of the Lord Chamberlain. The Theatres Act of 1843, while relaxing some of the provisions of its predecessors, strengthened the hands of the censor. A Select Committee of the House of Commons in 1866 reported favourably of the mode in which the censorship had been exercised; but about forty years later a strong movement for its abolition became apparent among dramatists, dramatic critics, and others. Theatre managers, while they suffered to a certain extent, were inclined to submit to the continuance of the censorship, because, once passed, a play was practically secure against any interference on the part of the authorities. The objectors urged that the censorship, while it had often allowed plays to pass which were written in a spirit by no means conducive to good morals, had habitually been used to prohibit those in which the subject was religious, or in which unpleasant facts had been honestly faced; and that in this way the drama was prevented from exercising any serious function, and kept out of touch with the most important sides of life. A joint committee was appointed, and its report in 1909 proposed a compromise likely to please both sides: that the examination of plays should continue, but that the submission of any play to its censure should be optional. If passed, a play should be virtually exempt from interference; if not passed, it could still be acted, but the Public Prosecutor should have the power of indictment for indecency, and the Attorney-General the power of appealing to a committee of the Privy Council, on the ground that it insulted a friendly

power, incited to a breach of peace, contained offensive personalities, or the like.

Player-pianoforte. See **PIANOFORTE**.

Playfair, LYON, Lord Playfair of St Andrews (1818-98), born at Chinnar, Bengal, became professor of Chemistry in Edinburgh University (1858-69), member of parliament (1868-92), and a peer (1892). He was postmaster-general (1873-74), chairman of ways and means and deputy speaker (1880-83). See his *Memoirs and Correspondence* by Sir Wemyss Reid (1899).

Plea, the answer of the defendant to the plaintiff's demand or charge. Pleas were divided formerly into pleas dilatory (where the party seeks to break down the conclusion of the action without entering into the merits of the case) and peremptory, Demurrers (q.v.), in Abatement (q.v.), special in bar, &c.; now the plea is usually Guilty or Not Guilty (see **CRIMINAL LAW**). In Scots law, plea means also a written statement by counsel of the legal grounds on which the party bases his case. In English civil procedure this is called *Pleading*; a term applied in criminal law to the accusation of the prosecutor or the answer of the accused. Pleadings have been much simplified by the Judicature Acts (1873-76). In the United States the New York legislature established a uniform procedure which has been adopted by most of the states. 'Pleas of the Crown' is an old term for criminal cases. In the Houses of Parliament pleading, as in the superior courts of law, must be conducted at the Bar (q.v.).

Plebeians. See **ROME (History)**.

Plebiscite, the name given, in the political phraseology of modern France, to a decree of the nation obtained by an appeal to universal suffrage. Thus, Louis Napoleon was chosen president, and subsequently emperor, by a plebiscite, and in 1870 obtained the sanction of a third plebiscite (7½ million votes). The word is borrowed from the Latin; but the *plebiscitum* of the Romans properly meant only a law passed at the *Comitia Tributa*—i.e. assembly of the *plebs*. The word is often used in Britain for an attempt to secure an expression of opinion on some special point of local interest by all the inhabitants of a district—often by means of return post-cards. The Treaty of Versailles introduced the principle in international frontier questions, several areas of the defeated countries being given power to decide their future nationality by a vote, or at least to express their preferences.

Plectognath, an order of Bony Fishes (q.v.).

Pledge. See **PAWN-BROKING**.

Pleiades, in Greek Mythology, were, according to the most general account, the seven daughters of Atlas and Pleione, the daughter of Oceanus. Their history is differently related by the Greek mythologists: according to some authorities, they committed suicide from grief, either at the death of their sisters, the Hyades, or at the fate of their father, Atlas (q.v.); according to others, they were companions to Artemis, and, being pursued by Orion (q.v.), were rescued from him by the gods by being translated to the sky; all authorities, however, agree that after their death or translation they were transformed into stars. Their names are Electra, Maia, Taygete, Aleyone, Celeno, Sterope (the invisible one), and Merope. The group of the Pleiades, called the 'Seven Stars,' is placed on the shoulder of Taurus. Looked at directly, only six stars are visible to the eye, though, if the eye is turned sideways, more can be seen; a good telescope shows fifty or sixty. Photography discloses thousands, with nebulae intermixed.

The name *Pleiad* is frequently applied to reunions of poets in septenary groups; and this use of the

word dates from the time of Ptolemy Philadelphus at Alexandria, who treated seven Greek poets with special distinction, and denominated them his *Pleiad*. His example was followed by Charlemaigne. But the name *Pleiade* is specially associated with a group of 16th-century French writers, of whom Ronsard (q.v.) and Du Bellay (q.v.) are the most notable, who endeavoured with marked result to reform the French language and literature after classical models. The other names are de Baif; Jean Dorat, or Danrat (q.v.), a celebrated Hellenist; Amadis Jamin; Étienne Jodelle; and Pontus de Thiard. In place of the two last, other authorities give Scévole de Saint Marthe and Marc Antoine Muret (q.v.); and, instead of Jamin, Belleau.

Plein-air, a term applied to painters, especially certain of the Impressionist school, who lay more importance on painting in the open air than in the studio. It is a development of the principles that 'the principal person in a picture is the light,' to quote Manet, and that no restriction ought to be placed on the artist as regards choice of subject. The chief difficulty in always painting a piece of nature just as one sees it is that this piece of nature may or may not be also a work of art. Aesthetic and natural beauty need not correspond. Though accuracy of colour can be obtained *en plein air*, selection of material and concentration of light can best be obtained in the studio. See **IMPRESSIONISM**.

Plesiosaurus. See **PLESIOSAURUS**.

Pleistocene (Gr., 'most recent') or **GLACIAL SYSTEM**. This system comprises the older accumulations belonging to the Quaternary or Post-Tertiary division. Almost all the molluscs met with in beds of this age are existing species. The system is termed Pleistocene or Glacial according as we have reference to the character of its organic remains or to the physical conditions under which the greater portion of its deposits were accumulated. These deposits are of very diverse nature and origin, and are subject to endless modifications, but nevertheless they show certain well-marked phases which are persistent over wide areas. Thus, throughout all northern Europe and the hilly and mountainous districts of the central and southern regions of the continent they exhibit the same general character and succession. The deposits of these regions consist for the most part of glacial and fluvioglacial detritus, which betoken the former presence of a great ice-sheet in northern Europe, and of extensive snowfields and glaciers in the mountain districts farther south. For an account of these deposits and glaciation generally, see **GLACIAL PERIOD**. In the regions outside of the glaciated areas the Pleistocene system is represented principally by fluvial accumulations, calcareous tufas, peat, and deposits in caves. The old river-gravels, &c. are well seen in the valleys of southern England, France, Belgium, central Europe, Spain and Portugal, Italy, &c., where they occur at the surface. But when they are followed into regions in which glacial and fluvioglacial accumulations are well developed they disappear underneath these or are dovetailed with them. Cave-deposits are of course met with even in glaciated regions.

Thus, in general terms, the Pleistocene deposits of northern Europe and the mountainous regions of the central and southern parts of the continent are of glacial origin, while the accumulations outside of those areas are chiefly fluvialite. The latter were for some time believed to be upon the whole younger than the former, but the two series are now generally recognised to be contemporaneous. The occurrence of fossiliferous beds intercalated between sheets of morainic matter (boulder-clay,

&c.) proves that the so-called glacial period was interrupted more than once by epochs of milder climatic conditions, during which the inland ice of the north retired from all the low grounds, while the great glaciers of the Alps, &c. shrank back to the inner recesses of the mountains. The organic remains obtained from fresh-water interglacial deposits have been correlated with those which occur in the river-accumulations of the non-glaciated tracts, and the result is that these accumulations are now admitted to be for the most part of interglacial age also. In short, the peat, river-deposits, tufas, and cave-accumulations are the equivalents in time of the glacial and interglacial deposits.

Life of the Period.—The plants and animals of the Pleistocene betoken great changes of climate—one series indicating an extremely cold or Arctic climate, while the other could only have flourished under uniformly element or even genial conditions. While a cold climate prevailed, such plants as *Dryas octopetala*, *Betula nana*, *Sedix polaris*, &c. flourished in the plains of Germany, and similar northern and Arctic forms clothed the low grounds of Switzerland. In Northern France grew birch, alder, larch, spruce, juniper, and yew, while in Northern Italy the Cembra pine flourished in the neighbourhood of Ivrea, and the Scots pine on the shores of Lake Varese. Contemporaneous with this flora we meet with land and fresh-water shells which are equally indicative of cold and nigenous conditions. And the same tale is told by the boreal and Arctic species of mollusks which occur more or less abundantly in the shelly clays of north Germany, Scandinavia, and the British Islands, and by the presence of northern forms in the Pleistocene marine beds of the Mediterranean area. The character of the land animals is quite in keeping with this evidence. Living in the low grounds of central and southern Europe at this time were reindeer, glutton, musk-sheep, Arctic fox, Alpine hare, marmot, snowy vole, mammoth, woolly rhinoceros, &c. The remains of these northern and Arctic plants and animals are met with both in glaciated countries and in the caves and fluvial deposits that occur in regions that never were covered with glacier-ice. The relics and remains of man himself also accompany the same flora and fauna. In strong contrast with such an assemblage of plants and animals is that of which we find abundant traces in interglacial beds and cave- and river-deposits. In northern France grew willows, hazels, ash, dwarf elder, sycamore, spindle-trees, perfumed cherry-tree, box, Clematis, common ivy, Judas-tree, Canary laurel, &c. The presence of that laurel, which flowers in winter, proves that the winters must have been very clement, and the other plants are indicative of a genial humid climate. The summers were not so hot and dry as they now are in France, and the winters were not so cold; and similar conditions obtained in Central Europe and the Mediterranean region—although the floras of those different zones were distinguished from each other by the presence of certain forms and the absence of others. The land and fresh-water shells associated with this flora are equally indicative of genial conditions, and similar evidence is supplied by the mammalia. Thus, we find a strange commingling of southern and temperate forms which is quite in keeping with the similar association in one and the same place of various plants which no longer live together in Europe. Amongst the animals were hippopotamus, hyena, serval, lion, leopard, various extinct species of elephant and rhinoceros, an extinct dwarf hippopotamus and machairodus. Contemporaneous with these were urus, bison, horse, stag, roe, saiga, beaver, hare, rabbit, otter, weasel, wild-

cat, fox, wild-boar, brown bear, grizzly bear, cave-bear, Irish deer, &c. The relics and remains of Palæolithic man likewise accompany this flora and fauna.

It is obvious, therefore, that the Pleistocene period was distinguished by great climatic oscillations. At one time the whole of northern and north-western Europe, down to the 50th parallel N. lat., was covered with a vast *mer de glace*, while from the Alps and all the considerable mountain-ranges of middle and southern Europe great glaciers descended to the low grounds. From ice-sheet and glaciers mighty rivers flowed all the year round, but in summer they rose in flood and inundated wide tracts, which in time became overspread with gravel, sand, and clay. It was under such conditions that a boreal and Arctic vegetation clothed the low grounds of middle Europe. While these conditions obtained, northern Europe appears to have been an area of high barometric pressure, and the dominant wind therefore blew strongly from north to south. During the winter season, when the rivers were much reduced, and the low-lying tracts, exposed to the floods of spring and summer, were laid bare, the glacial and fluvio-glacial deposits covering such regions were subject to this action by the prevalent wind, and much fine dust was swept southward. Similar conditions seem to have continued until the northern *mer de glace* had disappeared from the low-lying areas of middle Europe, which then formed a great region of steppes—a region of drifting sands, constantly subject to dust-storms. Jerboas (jumping hare), pouched marmots, bobac, pika, &c., were then common denizens of those wind-swept tracts. The same lands, which in some places were clothed with pine-forests, were roamed over by great herds of reindeer, mammoths, &c.—the bones of which sometimes occur together in such large numbers as to lead to the belief that the animals may have perished in snow-storms or 'blizzards.' It was then, too, that the reindeer and its associates flourished in the low grounds of southern France, where they were hunted by Palæolithic man. With the advent of interglacial times such nigenous conditions of climate passed gradually away—the ice-sheet vanishing entirely from the low grounds of north-western Europe, while the mountain-glaciers of central and southern regions dwindled to insignificance. Great migrations of plants and animals accompanied these changing conditions, the Arctic-alpine flora and northern and alpine fauna retreating northwards and retiring to mountain elevations, while the steppe fauna retired eastward into Asia. At the climax of interglacial times an extremely mild and genial climate, recalling that of the Pliocene, prevailed in Europe. The Canary laurel, the fig-tree, the Judas-tree, and many others flourished then as far north as Paris, in which region, therefore, frost must have been rarely experienced. Elephants, hippopotamuses, rhinoceroses, &c., and vast herds of bovine and cervine animals then wandered over all temperate Europe—the British area included. How often such changes of climate were repeated has not yet been definitely ascertained. The great cycle appears to have commenced towards the close of the Pliocene period. At all events it is in the latest Pliocene deposits that we encounter the earliest traces of approaching glacial conditions, as evidenced by the gradual immigration of boreal and Arctic forms of life into our present temperate regions. The earliest recognisable glacial epoch would seem to have been less severe than the next glacial stage, during which the European snowfields and glaciers attained their maximum development. The subsequent glacial epochs diminished successively in importance, and the same would appear to have been the case with the several interglacial epochs—the most genial epoch

having followed after the epoch of maximum glaciation, while those that succeeded became less and less strongly marked. There would seem, in short, to have been a gradual 'ringing-in' of the alternating cold and genial stages, until they finally died away and gave place to the conditions that now obtain. Most geologists are of opinion that during Pleistocene times Europe experienced at least three successive glacial epochs of extreme severity. But in the Alpine Lands there is clear evidence of four such epochs, the earliest of which was probably contemporaneous with the closing stage of the Pliocene period, as already mentioned. Moreover, it is well known that considerable climatic oscillations did not cease with the passing away of the latest of these four glacial epochs. On the contrary, the evidence supplied by the peat-bogs, raised beaches, and younger moraines of north-west Europe leaves us in no doubt that alternating glacial and interglacial conditions, of gradually diminishing importance, continued to affect our area down to quite recent times. If these later climatic oscillations be taken into account, then we must admit a succession of five or even six cold epochs, separated one from another by epochs of more genial conditions. The cause of such changes of level has been much canvassed by geologists. From the fact that evidence of submergence so frequently accompanies proofs of severe glaciation, it has been inferred that the subsidence may have been due to the presence of the ice. It has been suggested, for example, that the weight of the great ice-sheets which covered such vast regions in our hemisphere during glacial times may have displaced the earth's centre of gravity, and thus caused a rise of the sea in the north. Others, again, think it probable that under the pressure of a great ice-sheet the earth's crust may have yielded and sunk down more or less gradually. Some, again, have thought that a thick ice-sheet would exercise sufficient attraction upon the sea to cause it to rise upon the land. It must be admitted, however, that some of the oscillations of level which took place in Pleistocene times were on much too considerable a scale to be explained by any of the hypotheses referred to. Whatever influence the ice-sheets of the glacial period may have had upon the sea-level, it seems most probable that the greater oscillations were the result of considerable earth-movements, such as have taken place at many different stages of the world's history.

Pleistocene in other Continents.—In North America deposits of the same character and showing the same general succession as those of Europe are encountered—the glacial and interglacial conditions that characterised the latter continent having been equally characteristic of the former. The Pleistocene fauna of North America embraced Mastodon, a true elephant, species of horse, bison, beaver, peccary, bear, &c., and gigantic extinct forms of sloth, such as *Megatherium*, *Mylodon*, and *Megalonyx*. In South America the Pampean deposits have yielded a large number of remains of the great sloths and armadillos (*Glyptodon*), besides other mammals. There is abundant evidence also to show that snow-fields and glaciers had in Pleistocene times a considerable development in the Cordilleras, while in Fucgia ice seems to have overflowed much of the low grounds. The mountains of central Asia and the Chinese ranges show abundant traces of former glaciation; while the glaciers of the Himalayas are pigmies as compared with

their Pleistocene predecessors. So likewise the alpine tracts of New Zealand and Australia have been more or less extensively glaciated.

Cause of the Glacial and Interglacial Condition of the Pleistocene.—This question has given rise to much discussion, and many hypotheses and theories have been advanced, none of which, however, has proved satisfactory. The belief grows that the remarkable climatic changes owe their origin to extra-telluric causes, and that ere long astronomers may succeed in discovering what these causes were. In short, it seems highly probable that the peculiar climate of the Pleistocene was the result of variations in the amount of heat supplied by the sun.

Antiquity of Man in Europe.—All the human relics met with in Pleistocene deposits belong to what is known as the Palæolithic stage. Hitherto no indubitable evidence is forthcoming to show that man was an occupant of Europe before the glacial period. It is quite possible he may have been, but we lack evidence sufficient to prove this. He certainly lived, however, throughout the earlier glacial and interglacial conditions described above. It is remarkable that no trace of his occupation has been met with in beds of later date than the last great Baltic glacier. If we were to judge from negative evidence (which it is always unsafe to do) we should infer that he vanished from Europe at or about the time that most extensive ice-flow was melting away. The oldest human relics hitherto discovered in beds of a later date are Neolithic.

Wright's *The Quaternary Ice Age*; Chamberlin and Salisbury, *Geology*, vol. iii.; Penck and Bruckner, *Die Alpen im Eiszeitalter*; Wahnschaffe, *Die Ursachen der Oberflächengestaltung des Norddeutschen Flachlandes*.

Plenipotentiary. See AMBASSADOR.

Pleochroism. In some crystals, such as some specimens of topaz, three distinct colours may be observed on looking through them along three rectangular axes. In intermediate directions intermediate tints may be observed; and this property is that of pleochroism or polychroism. In some other cases a similar range of intermediate tints may be observed, lying between two extreme tints visible along two axes (dichroic crystals—e.g. tourmaline, ruby, sapphirine, and some specimens of mica).

Plesiosaurus (Gr. *plēsios*, 'near,' *sauros*, 'a lizard'), the type or leading genus of a family

Plesiosaurus dolichodeirus.

(Plesiosauridae) of fossil sea-reptiles, which are characteristic of the Mesozoic systems. The skull of *Plesiosaurus* is small and depressed, with a short

mandibular symphysis. The teeth (sunk in distinct sockets) are long, slender, and cylindrical, and show fine longitudinal ridges on the enamel. The most striking peculiarity of the vertebrae is the great length of the neck portion, which was composed of from 30 to 40 vertebrae—the anterior ones being generally very small. The cervical vertebrae consist of a centrum, neural arch, and two ribs, which are firmly articulated to the centra of the vertebrae, the terminal faces of which are more or less biconcave. In the dorsal vertebrae the ribs are articulated to diapophyses from the neural arch; and in the tail they gradually descend again to the sides of the centrum. The tail is much shorter than in Ichthyosaurus (q.v.). In the abdominal region the extremities of each pair of ribs are connected below by the development of the hæmal spine. The scapulae are of moderate size and widely separated. The two pairs of limbs correspond closely in structure. The humerus and femur are comparatively short and distally much expanded; the radius and ulna, tibia and fibula are short and flat; the 'hand' and 'foot' are long, the phalangeals being increased in number beyond the normal complement. The limbs were covered with integument so as to form simple undivided paddles, as in the turtle. Plesiosaurus was undoubtedly aquatic, and probably haunted the shallow seas and estuaries of Mesozoic times. Its remains have been met with frequently in a fine state of preservation. Some specimens exhibit embryos within the abdomen, and hence must have produced their young alive. Gastrolites often accompany the skeletons. Cimoliosaurus, met with in the Jurassic and Cretaceous strata of Europe, North and South America, and New Zealand, attained a length of between 30 and 45 feet. Pliosaurus was another genus, with a shorter neck (the vertebrae twelve in number) and a comparatively larger head than Plesiosaurus. In this genus the lower jaw was sometimes nearly 6 feet long.

Plessis-les-Tours. See TOURS, LOUIS XI.

Plethon, GEORGIOS GEMISTOS, a Greek scholar, was most probably a native of Constantinople, and found employment in the Peloponnese under the 'despots' Manuel and Theodore Palæologus. He was sent as a deputy to the council held at Florence in 1439, and here, if he did little for the union of the Eastern and Western Churches, he did much to spread a taste for Plato. He returned to Constantinople, and died there about 1455. See vol. i. of F. Schmitz's *Geschichte der Philosophie der Renaissance* (Jena, 1874).

Plethora (Gr. *plêthōra*, 'fullness'), a general excess of blood in the system. It may arise either from too much blood being made or from too little being expended. The persons who become plethoric are usually those in thorough health, who eat heartily and digest readily, but who do not take sufficient bodily exercise, and do not duly attend to the action of the excreting organs. With them the process of blood-making is always on the increase, and the vessels become more and more filled, as is seen in the red face, distended veins, and full pulse. The heart is often dilated and the seat of fatty or other form of degeneration, and hence palpitation, shortness of breath, and probably a sleepy feeling may arise; and there is frequently a raised blood-pressure, by which the morbid condition is aggravated. The state of plethora thus gradually induced may be extreme without any functions materially failing, and yet the subject is on the verge of some dangerous malady, such as apoplexy, or structural disease of the heart or great vessels, or of the lungs, kidneys, or liver.

Pleurisy, or inflammation of the investing membrane of the lung (*pleura*), is one of the most common diseases of the chest. It is very often, but by no means invariably associated with inflammation of the substance of the lung, commonly known as *Pneumonia* (q.v.). Pleurisy without pneumonia is much more common than pneumonia without pleurisy. When both are present, but pneumonia preponderates, the correct term for the affection is *pleuro-pneumonia*, although it is frequently spoken of simply as pneumonia, probably in consequence of the remedies being applied mainly to it, as the more important of the two elements in the compound malady.

The pleura being a serous membrane, its inflammation is attended by the same course of events as have been already described in our remarks on the two allied diseases, *Pericarditis* and *Peritonitis*. The inflammation is of the adhesive kind, and is accompanied by pain, and by the effusion of serum, of fibrinous exudation, or of pus into the pleural cavity. In the last case it is called *empyema*. In consequence of the anatomical relations of the pleura—one part of the membrane (the parietal) lining the firm walls of the chest, while the other part (the visceral) envelops the soft and compressible lung, and these opposed surfaces being freely movable on one another—it follows that very different effects may be produced by its inflammation. For example, the visceral layer may be fixed to the parietal layer, so as to prevent all gliding movement between them, and to obliterate the pleural cavity (similarly to what often happens in *Pericarditis*, see PERICARDIUM); or the two surfaces which are naturally in contact may be abnormally separated by an effusion of serum between them; or, from a combination of these results, the opposite surfaces of the pleura may be abnormally united at some points, and abnormally separated at others.

The symptoms of acute pleurisy are rigors, pain in the side, fever, difficulty and rapidity of breathing, cough, and discomfort in certain positions; and of these the most marked is the sharp pain in the side, often described by the patient as like a knife between the ribs. The pain, often very severe, and often limited to one small spot, is usually at the lower part of the affected side; but is occasionally felt in other parts—as in the shoulders, in the hollow of the armpit, beneath the collar-bone, along the breast-bone, even in the loins, simulating lumbago; or, in the abdomen, so as to suggest peritonitis or appendicitis. In some cases it is altogether absent. The pain is increased by percussion, by pressure between the ribs, by a deep inspiration, by cough, &c.; and the patient is often observed to shrink from drawing more than a short and imperfect breath. Cough is not invariably present, although it is an ordinary symptom. It is short, suppressed as far as possible by the patient, and is either dry or accompanied by the expectoration of slight catarrh. If much frothy mucus is brought up it is a sign that Bronchitis (q.v.) is also present, and the appearance of rust-coloured sputa indicates the co-existence of pneumonia. Although the above-named symptoms, especially when most of them occur together, afford almost certain evidence of the existence of pleurisy, yet to the physician the physical signs are still more valuable, especially those furnished by auscultation and percussion. The *friction-sound*, characteristic of pleurisy in the dry stage in its most marked form, resembles the creaking of leather: the patient is often himself conscious of the grating sensation produced by the rubbing of the pleural surfaces; and it may sometimes be felt by a hand laid on the affected part. If fluid effusion be present the friction-sound is

lost; but dullness on percussion replaces the normal resonance over the area occupied by the fluid.

Pleurisy frequently arises after unusual exposure to cold, and when it persists in a severe form with effusion, it is often an early manifestation of tuberculosis, which appears later in the lung; it often complicates rheumatic fever and Bright's disease; but it may be occasioned by mechanical violence (as by a penetrating wound of the thorax, by the splintered ends of a broken rib, &c.), or by the accidental extension of disease from adjacent parts. The disease may terminate in resolution and complete recovery; or in adhesion, which often only causes slight embarrassment of breathing; or it may end with such a retraction of one side of the chest as to render the corresponding lung almost useless; or it may cause death, if the effusion is very copious, and is not removed by tapping. It is seldom that simple pleurisy proves fatal; but empyema in adults is a very serious disease.

In the treatment of pleurisy rest in bed, careful nursing, and light diet are essential. In acute cases in the early stage cupping, application of a large plaster or strips of plaster to diminish movement, or blistering is generally indicated. When effusion has taken place, purgatives, diuretics, and absorbents should be given. But when fluid is from day to day, it is usually desirable to draw it off by tapping. If the fluid be serous this usually greatly hastens recovery. Even when it is purulent (empyema) aspiration, repeated when necessary, is often successful in the case of children; but more generally, especially in adults, free opening and drainage of the cavity by removal of part of a rib alone affords hope of cure.

Pleurisy Root. See BUTTERFLY WEED.

Pleurodynia is the name sometimes applied to neuralgia of the chest-wall, which may simulate closely the pain of pleurisy.

Pleuronectidæ. See FLAT-FISH.

Pleuro-pneumonia. The disease of this name in the human subject is mentioned at PLEURISY; the following article deals with the disease in cattle so called. Pleuro-pneumonia Contagiosa is a contagious febrile disease of cattle supposed to have originated in central Europe and thence to have been conveyed to all parts of the world. It cannot be certainly traced further back than 1769, when it was known in eastern France as *Muric*. Not till 1802 was it seen in Germany, 1824 in Russia, 1841 in Great Britain and Ireland, 1843 in the United States, 1858 in Australia, and 1864 in New Zealand. The causal organism of the disease is an exceedingly minute micrococcus, discovered in 1898 by MM. Nocard and Roux with collaborators. Inoculation of the virus, after an incubative period of from 8 to 28 days, induces extensive inflammatory exudations in the substance of the lungs and surfaces of the pleura, finally resulting in consolidation of some portions of the lungs, occlusion of the air-tubes, plugging of the blood-vessels, and, generally, adhesion of the pleural surfaces.

It is now clearly demonstrated that pleuro-pneumonia never occurs independently of infection, that it may be favoured by overcrowding, exposure, wet, damp, dirty hovels, that these influences may predispose an animal to succumb more readily, or, in other words, to become a more suitable soil for the increase of the specific organism to which the disease is due, but they do not originate it.

There is much variety in the manifestation of the disease. In some instances, especially during its first outbreak in a district, it runs a rapid course, destroying life in the course of a few days;

in other cases, and these are the most numerous, its onset, course, and termination occupy a period of from two to eight weeks, or even longer; some animals recovering after the shorter periods, whilst others become emaciated, finally succumbing to an exhaustive diarrhoea, imperfect aeration of the blood, hydrothorax or water in the chest, the depressing influence of degenerated animal materials absorbed into the blood, and anaemia. The more prominent symptoms are slight rigors or shiverings, elevation of temperature, loss of appetite, secretion of milk diminished, an occasional cough is heard which is dry and hard in character, rumination becomes irregular, the bowels rather constipated, and the urine is scanty and high-coloured. In cases that do not begin to recover at this stage the signs of general disturbance more or less rapidly increase: the cough becomes more persistent, the respiratory movements increase in frequency, when the animal stands the elbows are turned out, and whilst recumbent the weight of the body is thrown upon the sternum or breast-bone—a posture in which, owing to the anatomical conformation of this bone, the animal can most readily expand the chest. The breathing is often but not always accompanied by a moan or grunt.

Experience has led the great majority of professional men to the conclusion that the disease is little influenced by medicinal remedies; it runs a course. If the dose of the contagium is small, or the animal able to withstand a larger one, it terminates spontaneously in apparent recovery; but an animal which has thus apparently recovered still contains the germs and products of the disease, and remains a source of danger to others for an indefinite period, probably during the remainder of its existence. If, on the other hand, the dose of the specific cause be strong or the animal weak, death soon occurs. By the provisions of the Pleuro-pneumonia Act, 1889, all cattle suffering from the disease, as well as those in contact with them, have to be slaughtered, part of the loss being borne by the local authority.

Plevna (Bulg. *Pleven*), a town of Bulgaria, 19 miles S. of the Danube and 85 N.E. of Sofia, with 28,000 inhabitants. Here in 1877 Osman Pasha, the Turkish general, after defeating the Russians in several engagements, entrenched himself against their reinforced and superior numbers early in September, and repulsed their endeavours to take the place by storm; but, after making an unsuccessful attempt to cut his way through the investing Russian army, he was compelled, provisions and ammunition running short, to capitulate (10th December) with 42,000 men and 77 guns. The siege cost the Russians 55,000 men, the Rumanians 10,000, the Turks 30,000. See W. V. Heibert, *The Defence of Plevna* (1895).

Pleximeter. See PERCUSSION.

Pleyel, IGNAZ JOSEPH, born 1st June 1757 at Ruppertsthal, near Vienna, studied under Haydn and in Italy, and in 1783 was made Kapellmeister of Strasburg Cathedral. In 1791 he visited London, and he harmonised many of the melodies for Thomson's *Collection of Scottish Songs*. At Strasburg, during the French Revolution, he barely escaped with his life as a royalist. In 1795 he opened a large music shop in Paris, and in 1807 joined thereto a pianoforte manufactory. He died in Paris, 14th November 1831. His compositions consisted of quartets, concertos, and sonatas.

Plica Polonica was the name given to a disease of the scalp, in which the hairs became matted together by an adhesive and often fetid secretion, and which was at one time prevalent in Poland, although it occasionally occurred in other

countries. The hair was found, on microscopic investigation, to be infested with a fungus of the genus *Trichophyton* and with vermin. The only treatment that was beneficial was the removal of the hair, and cleanliness; but, as it was popularly believed in Poland that this affection afforded a security from all other sickness and misfortune, it was often difficult to persuade patients to have recourse to these means.

Plimsoll, SAMUEL, 'the sailors' friend,' was born at Bristol on 10th February 1824. In his seventeenth year he became clerk in a Sheffield brewery, and rose to a position of trust in the firm. In 1854 he started business on his own account, in the coal trade, in London. Shortly afterwards he began to interest himself in the sailors of the mercantile marine, and the dangers to which they were exposed. He accumulated a mass of facts proving that the gravest evils resulted from the wilful employment of unseaworthy ships, from overloading them, and under-manning them, from bad stowage, and from over-insurance; unscrupulous owners insured rotten or 'coffin' ships at a value greatly exceeding their real value, and sent them to sea, hoping they would founder, by which means they would make bigger profits than they could make by legitimate carrying of merchandise. Failing to induce parliament to take legislative steps to put an end to these evils, Mr Plimsoll himself entered parliament, for Derby, in 1868; but it was not until he had published *Our Seamen* (1873) and had made an appeal to the general public that he succeeded in getting passed the Merchant Shipping Act in 1876, to supersede temporary measures passed during three preceding sessions. By this act the Board of Trade was empowered to detain, either for survey or permanently, any vessel deemed unsafe, either on account of defective hull, machinery, or equipments, or improper loading, or overloading; a penalty not exceeding £300 was incurred by any owner who should ship a cargo of grain in bulk exceeding two-thirds of the entire cargo, grain in bulk being especially liable to shift on the voyage; the amount of timber that might be carried as deck cargo was defined, and enforced by penalties; finally, every owner was ordered to mark (often called the 'Plimsoll Mark') upon the sides of his ships, amidships, a circular disc, 12 inches in diameter, with a horizontal line 18 inches long drawn through its centre, this line and the centre of the disc to mark the maximum load-line—i.e. the line down to which the vessel might be loaded, in salt water. Failure to comply with this last regulation exposed the owner to a fine not exceeding £100 for each offence. By an Act of 1894 the fixing of the load-line is taken out of the owner's discretion and made a duty of the Board of Trade. Mr Plimsoll retired from parliamentary life in 1880. But he did not slacken his efforts to make the sailors' calling safer: in 1890 he published a work on *Cattle-ships*, exposing the cruelties and great dangers connected with the shipping of live cattle across the ocean to British ports. He died 3d June 1898. See Japp, *Good Men and True* (1890).

Plinlimmon, or **PLYNLIMMON**, a large mountain-mass (2469 feet) of Wales with three summits, on the boundary between Montgomery and Cardigan, 10 miles W. of Llanidloes. The name is said to be a corruption of a Celtic word signifying Five Rivers, five rivers having their sources on its slopes; one is the Severn, another the Wye.

Plinth, the square member at the bottom of the base of a Column (q.v.). Also the plain projecting band forming a base of a wall.

Pliny (GAIUS PLINIUS SECUNDUS), called the

Elder, to distinguish him from his nephew, came of a North Italian stock possessing estates at Novum Comum (*Como*), where he was born 23 A.D. He claimed to be a compatriot of Catullus, but the reference is too vague to warrant the assumption that their common birthplace was Verona. His education was carried on in Rome, under every advantage of wealth and family connection, till, when about twenty-three years old, he entered the army, serving on the staff of L. Pomponius Secundus, then conducting a campaign in Germany. He became colonel of his regiment (a cavalry one), and while attentive enough to his military duties to make a special study of the throwing of missiles from horseback, on which he wrote a treatise (*De Jactatione Equestri*), and to compile a history (afterwards published in twenty books) of the Germanic wars, he gratified his thirst for miscellaneous knowledge by a series of scientific tours, investigating the region between the Rhine, the Elbe, and the Weser, and the sources of the Danube. Returning to Rome in 52 with Pomponius, he studied for the bar, at which he practised just long enough to satisfy himself that his aptitudes were not of the forensic order. Accordingly he withdrew to his native Como, and there, during the greater part of Nero's reign, devoted himself to reading and authorship encyclopædic in their range. Apparently for the guidance of his nephew he wrote in three books his *Studiosus*, a treatise defining the culture necessary for the orator before entering on his career, and also for his nephew the grammatical work, *Dubius Sermo*, in eight books. About the close of Nero's life he was appointed procurator (collector of the imperial revenues) in Spain, where in 71 he heard of his brother-in-law's death, by which he became guardian of his sister's son, Pliny the Younger, whom, on his return to Rome two years after, he adopted. Vespasian, by this time emperor, whom he had known in the German campaign, was henceforth his most intimate friend, but court favour did not wean him from study, and so we find him bringing down to his own time, in thirty-one books, the history of Rome, by Aufidius Bassus. A model student, amid metropolitan distraction, he began work by candle-light, in autumn before the day was spent, and in winter by 1 or 2 A.M. Ere dawn he would wait on the emperor and discharge the imperial commissions imposed on him, after which he returned home once more to his books. A slight repast intervening, he resumed work, in summer lying in the sunshine while he took notes or extracts from what was read to him. True to his maxim that no book was so bad but some information might be got from it, he seized every opportunity of jotting down all that interested him either as reader or auditor. A cold bath, followed by a slender meal and a brief siesta, preceded the next spell of work, at which he continued till *cena*, the Roman dinner, at 3 p.m. Even then he listened to the reading of some book, on which he commented. Such was his life when at court; but at his country seat his studies were uninterrupted—an attendant reading to him even in the bath, or writing to his dictation while he was under the *masseur* or anointer (*adipos*). On his journeys by land or water his secretary with book and tablets was always at hand. By this lifelong application he amassed materials enough to fill the 160 volumes of manuscript written very small on both sides which, after using them for his *Historia Naturalis* (published 77), he bequeathed to his nephew. His life, uneventful and studious, was quite dramatic in its ending. In 79 he was in command of the Roman fleet stationed off Misenum when the great eruption of Vesuvius was at its height. Eager to witness the phenomenon as closely as possible, he landed at Stabiae

(*Castellamare*). Next day, on the shore, examining whether a contrary sea would allow him to escape, he succumbed to the stifling vapours rolling down the hill.

His *Historia Naturalis* alone of his many writings survives. Under that title the ancients classified everything of natural or non-artificial origin—not only botany, zoology, and mineralogy, but geography, meteorology, and astronomy. Pliny, however, extends even this elastic definition, and adds to his work by digressions on human inventions and institutions, devoting two books to a very valuable, if misplaced, history of fine art. He dedicates the whole to Titus, in a turgid, ill-composed epistle, the low literary level of which is maintained throughout. Nor is his artistic, sometimes obscure, style redeemed by much scientific faculty in handling his theme. He did not pretend to original research, but the philosophical method which sometimes distinguishes the mere compiler is equally foreign to his pages. His observations, made at second-hand, are presented with no discrimination between the true and the manifestly false, between the probable and the simply marvellous. He can even be convicted of having misunderstood the authorities on whom he relies. But with every deduction made from it as to matter and form, his compilation is a praiseworthy monument of reading at once extensive and minute, and supplies us with information on an immense variety of subjects as to which, but for him, we should have remained in the dark.

The most convenient text for the student is that of Jan and Mayhoff (5 vols. 1892-1909), which embodies the best results of the recensions by Sillig and Detlefsen. The *Chrestomathia Pliniana* (Berlin, 1857) of the great archaeologist Ulrichs is particularly valuable for its comments on fine art; while of translations the soundest and most readable is that of Lüttich, in French, published along with the original Latin (Paris, 1848-50).

Pliny (GAIUS PLINIUS CÆCILIUS SECUNDUS), the Younger, was born at Novum Comum, 62 A.D. His education, after his tenth year, when his father died, was conducted under the eye of his mother, Plinia, of his tutor Virginius Rufus, of whose worth, intellectual and moral, he has left a beautiful memorial, and of his uncle who adopted him. He early displayed high literary aptitude, wrote a Greek tragedy in his fourteenth year, and made such progress under Quintilian that, like his friend Tacitus, he became noted as one of the most accomplished men of his time. His proficiency as an orator enabled him, when not more than eighteen, to plead in the Forum, and brought him much practice, not only at the Centumviral bar, chiefly in will-cases, but also before the senate. Official appointments came to him in quick succession. Then, still young, he served as military tribune in Syria, where he frequented the schools of the Stoic Euphrates, and of Artapanodus; at twenty-five, the earliest possible age, he was *questor Cæsaris*, then praetor, and afterwards consul in 100 A.D., in which year he wrote his laboured panegyric of the Emperor Trajan. In 103 he became propraetor of the Provincia Pontica, but vacated the post in two years, and, among other offices, held that of curator of the Tiber, chiefly for the prevention of floods. He married twice; his second wife, Calpurnia, granddaughter of Calpurnius Fabatus, is fondly referred to in one of his most charming letters for the many gifts and accomplishments with which she sweetened his rather invalid life. He died without issue, but in what year is unknown.

It is to his letters that Pliny owes his assured place in literature as one of the masters of the epistolary style. An avowed imitator of Cicero, he has caught much of the charm of his model, while his Latinity is hardly, if at all, inferior in purity and

ease. His meaning, though never obscure, is generally fuller than his expression, and, reading between the lines, we discern the features of a truly lovable man, quite aware of his strong as of his weak points, much given to hospitality, and always pleased to help a less favoured brother, such as Suetonius or Martial. We derive from him not a few of our distinctest impressions of the public and private life of the upper class in the 1st century; above all, it is from his correspondence with Trajan that we get our clearest knowledge of how even the most enlightened of the Romans regarded the then obscure sect of the Christians. It appears that a person acknowledging himself a Christian was liable to punishment, even to death. When under examination, however, no Christian would admit anything further than his practice of meeting with his co-religionists on an appointed day before it was light; singing a hymn to Christ as God (or 'as to a God'—*quasi deo*); and taking an oath which bound him to no crime, but never to commit theft, robbery, adultery, and malfeasance, and never to deny a deposit. Even when put to the torture, two female slaves, said to be deaconesses, confessed nothing more to Pliny, who thereupon consulted the emperor as to how he might stop the spread of what he could only call 'a depraved and extravagant superstition.' Trajan declined to lay down a general rule for dealing with the Christians; he recommended that they should not be sought out on suspicion, but that, if accused and convicted of holding that faith, they should be punished. Accusations unsupported by an accuser were not to be received, while suspected cases were to have an opportunity of clearing themselves by offering prayers to the Roman gods (*dus nostros*).

For text, see Keil (Leip., 1853) and Müller (Breslau, 1903), while a useful selection with a good commentary has been published by Church and Brodribb (1871). Melmoth's translation (1746) is free and eminently readable; Orriery's, of the *Epistole* (1751), is still esteemed; Miss Hutchinson corrects Melmoth (with text, 1915). See Dill, *Roman Society from Nero to Marcus Aurelius* (1905).

Pliocene System. Strata belonging to this system are restricted in Britain to a limited area in Essex, Suffolk, and Norfolk; but a few isolated patches occur also in Cornwall and Kent. They consist of irregular lenticular beds of sands and shelly gravels, &c., which never occur altogether in one place. The whole series probably does not exceed 120 feet in thickness, and comprises the following groups arranged in descending order:

- CHROMER FOREBELL-BELT:** fresh-water or estuarine silts, clays, and sands, with layers of peat; 10 to 70 feet thick. The fossils are land and fresh-water molluscs, many land-plants, and numerous unworked remains.
- CHILLESFORD BEDS:** sands and clays, 6 to 16 feet thick, contain marine shells, some two-thirds of which are existing Arctic species; represented in the north of Norfolk by the **WYNDHURST CRAG**.
- NORWICH CRAG:** fluviatile gravel, sand, and loam; 5 to 10 feet thick. Fossils, chiefly marine molluscs; several land and fresh-water shells; and numerous mammalian remains—hence the name of 'mammaliferous crag' sometimes applied to this group. Of the shells 93 per cent. are living species—14½ per cent. being northern forms.
- RED CRAG:** red ferruginous shelly sand, 25 feet thick, but local and inconsistent. About 90 per cent. of the numerous shells occurring in this deposit are existing species—10½ per cent. being northern forms.
- ST EUSTICE BEDS:** clays and gravels, near St Eust, Cornwall; many shells, about 40 per cent. being of extinct species.
- WHITE OR CORALLINE CRAG:** shelly sands and clays; fossils abundant; 84 per cent. of the shells are living species, and of these 5 per cent. are northern forms. Polyzoa (popularly called *corals*) are numerous, hence the name sometimes applied to this group.
- LENNAM BEDS:** sands, &c., occupying 'pipes' or hollows in the chalk of the North Downs, some 600 feet above the sea.

On the Continent Pliocene marine deposits are met with in various countries, usually in maritime regions, as at Antwerp and in the west of France in

the Cotentin, Morbihan, and Aquitaine. But it is in the Mediterranean basin that this system attains its greatest development. Thus, at various points along the foot of the Alps in North Italy Pliocene beds appear, and they likewise occur along both sides of the Apennines, forming the sub-Apennine formation; while in Sicily they attain a thickness of 2000 feet. In middle Europe the most important Pliocene strata are the fresh-water beds of the Mayence basin, and the fresh and brackish water beds of the Tertiary basin of Vienna. The calcareous tufas of France and Italy belonging to this system are notable for their plant-remains.

Life of the Period.—The flora of Pliocene times indicates a more temperate climate than that of the preceding Miocene. Many Miocene forms still lived in Europe, but the palms and other characteristic Miocene plants had disappeared. Ivy, platanus, liquidambar, various maples, many walnut trees, elms, hornbeams, magnolia, tulip-tree, Canary laurel, oleander, vine, glyptostrobilus, sassafras, and others ranged from Tuscany to the heart of France—such plants as beech, poplar, lime, oak, sassafras, maples, bamboos, vines, &c. growing amongst the mountains of Cantal. The general character of the flora recalls the floras of distant regions—North America, the Canary Islands, eastern Asia, and Japan. The abundant evergreen plants of the period seem to have grown chiefly on the low grounds; at higher elevations pines and deciduous trees were the prevailing forms. The flora of the Norwich Crag shows that towards the close of the period the British area was clothed with a vegetation somewhat similar to that of the present. The molluscan fauna includes an increasing number of living species. In the lower groups of the system the general facies of the shells is southern, but in the upper groups the southern types decrease in importance and are gradually replaced by temperate and northern forms. Amongst land animals we find several survivors from earlier times, such as *Dinotherium* and *Mastodon*, with which co-existed many other pachyderms—elephants, rhinoceroses, hippopotamuses, and tapirs. Herbivorous quadrupeds also abounded—horses, giraffes, and various cervine and bovine forms. Carnivores (panthers, bears, wolves, &c.) were well represented, and apes and monkeys also formed a marked portion of the fauna. The Pliocene beds of Pikermi in Attica, and of India (Siwalik group), have yielded a large number of extinct and living types. At Pikermi occur the remains of many ruminants, amongst which are species of giraffe, *Helladotherium*, and various cervine and bovine forms, together with *Mastodon*, rhinoceros, *Dinotherium*, hyæna, and others. The Siwalik beds contain *Hyænarctos*, *Machairodus*, and other Miocene forms, and *Sivatherium* and *Bramatherium*, gigantic four-horned animals allied to antelopes. With these are associated many living genera, such as *Felis*, *Hyæna*, *Canis*, *Bos*, *Bison*, *Capra*, *Ovis*, &c. It may be noted that from the Pliocene of the Upper Missouri region of North America remains of an abundant mammalian fauna have also been obtained—a fauna which had a strikingly oriental aspect.

In Pliocene times the Mediterranean covered many tracts which are now dry land. The valley of the Po then formed a great arm of the sea which penetrated into the mountain-valleys of the Alps, while Italy and Sicily were largely submerged. Considerable tracts in the maritime districts of southern and western France were likewise under water. The sea also overflowed some part of the south of England (Cornwall and Kent) and encroached upon the low grounds of Belgium and East Anglia. The long arms of the sea, which in the Miocene period had stretched from the Medi-

terranean through France into Switzerland and the valley of the Rhine, had vanished, while fresh-water and saline lakes occupied Transylvania and the Vienna basin, which had been more or less open sea in Miocene times. Much of south-eastern Europe, however, continued submerged—the sea extending through the Aralo-Caspian depression into Asia. One of the most notable events of the Pliocene was the birth of Etna, Vesuvius, and the now extinct volcanoes of Central Italy. In early Pliocene times the climate was mild and genial, but the conditions became less so during the closing stages of the period. This change is evidenced particularly by the increasing number of northern molluscs and the occurrence of ice-floated erratics in the English Pliocene.

Pliosaurus. See *PLESIOSAURUS*.

Plock (Ger. *Plock*), a town of Poland, on the right bank of the Vistula, 60 miles NW. of Warsaw. Its principal building is the cathedral, built in the 11th century. One of the oldest towns in Poland, Plock was the capital of ancient Masovia, and was severely ravaged by the heathen Prussians, the Lithuanians, and the Swedes. Pop. 25,800 (many Jews).

Ploiești, a town of Rumania, 37 miles by rail N. of Bucharest, with petroleum-refineries and a large trade in wool; pop. 60,000.

Plombières, a spa in the French department of Vosges, 14 miles S. of Epinal, sprung into fashion through the favour of Napoleon III., though the virtues of its waters were known ever since the times of the Romans. There are nearly thirty springs, ranging in temperature from 66° to 150° F.

Plotinus, the most original and important philosopher of the Neoplatonic school, was born at Lycopolis in Egypt in 205 A.D., and studied philosophy under Ammonius Saccas. In 242 he joined Gordianus' expedition to Persia, in order to study the philosophy of India and Persia; but the emperor being murdered in Mesopotamia, he returned hurriedly to Antioch, whence, in 244, he went to Rome. His lectures here were attended not only by crowds of eager youths, but men and women of the highest circles flocked to hear him. Not only Neopythagorean and Neoplatonic wisdom, but asceticism and the charm of a purely contemplative life were the themes on which he, in ever new variations, and with an extraordinary depth and brilliancy, held forth; and such was the impression his earnestness made upon his hearers that some of them really gave up their fortune to the poor, set their slaves free, and devoted themselves to a life of study and ascetic piety. It is hardly surprising to find that his contemporaries coupled with his rare virtues the gift of working miracles. Sixty years old, he thought of realising Plato's 'Republic,' by founding an aristocratical and communistic commonwealth; and the Emperor Gallienus was ready to grant a site in Campania for his 'Platonopolis;' but he died near Minturnæ in 270. Although he began to write very late in life, he yet left fifty-four books of very different size and contents to the editorial care of his pupil Porphyry, who arranged them in six principal divisions, each subdivided again into nine books or *Enneads*.

Plotinus' system was based chiefly on Plato's, combined with Neopythagoreanism and the oriental theory of Emanation—i.e. the constant transmission of powers from the Absolute to the Creation, through several agencies, the first of which is 'Pure Intelligence,' whence flows the 'Soul of the World,' whence, again, the souls of 'men' and 'animals,' and finally 'matter' itself. Men thus belong to two worlds, that of the senses and that of Pure Intelligence. It depends upon ourselves, however,

to which of the two worlds we direct our thoughts most and belong to finally. The ordinary virtues, as justice, moderation, valour, and the like, are only the beginning and very first preparation for our elevation into the spiritual realm; purification is a further step, to which we attain partly through mathematics and dialectic; and the abandonment of all earthly interests for those of intellectual meditation is the nearest approach to the goal. The higher our soul rises in this sphere of intellect, the deeper it sinks into the ocean of the good and the pure, until at last its union with God is complete, and it is no longer thought but vision and the ecstasy which pervades it. These are a few snatches of Plotinus' philosophical rhapsodies, to which may be added his mysterious belief in a kind of metempsychosis, by which souls not sufficiently purified during life return after death, and inhabit, according to their bent, men, animals, and even plants. He further held somewhat fantastic views as to gods and demons, and professed faith in astrology and magic. His was the last attempt by the ancient world to solve the great problems not by ratiocination, but through introspective mysticism; and his mode of thought had very unmistakable influence on early Christian philosophy, modern theosophy, and various German idealistic systems.

See NEOPLATONISM and works there cited; Inge's *Philoctatus* (1918); Stephen McKenna's translation (1917 et seq.); and Caird's *Evolution of Greek Philosophy* (1904).

Plots must be distinguished on the one hand from Assassinations (q.v.) and on the other from Rebellions (q.v.). They involve the elements of secrecy and conspiracy, but have not always political assassination for their object, nor do those who carry them through, or attempt to do so, put arms in the hands of a great number of men. The subjoined list only professes to give a selection of the more noteworthy plots of history, intended to supplement the lists given under ASSASSINATION and REBELLION. Details of most of them will be found under separate articles.

Catharine's Conspiracy, 63 B.C.	Rye-house Plot against Charles II., 1683.
Curio's Plot in Venice, 1310.	Assassination Plot to kill William III. of England, 1696.
Mario Faleri's Plot in Venice, 1355.	Plot of Catharine against Peter III. of Russia 1762.
Plot of Fieschi against Andrea Doria at Genoa, 1547.	Colonel Despard's Plot against George III., 1802.
Baid of Ruthven in Scotland, 1582.	Plot of Cadoudal and Fichereu against Napoleon, 1802.
Balington's Plot against Elizabeth, 1586.	Malet's Plot against Napoleon, 1812.
Death of Prince Demetrius in Russia, 1601.	Cato Street Conspiracy, 1820.
Gowrie Conspiracy in Scotland, 1600.	Osmen's attempt upon Napoleon III., 1858.
Gunpowder Plot in England, 1605.	Numerous Nihilist plots in Russia from 1881.
Titus Oates' pretended Popish Plot, 1678.	Abduction of Alexander of Bulgaria, 1886.
Meal-tub Plot, 1679.	

Plough. The first in order and importance of agricultural operations is the breaking up of the soil, and the implement employed most largely for this purpose is the *plough*. The general form of the mould-board is known to every one, and to the unobservant eye it appears to be a very simple and even primitive tool; nevertheless, much mechanical skill and ingenuity have been expended in perfectly adapting it to its work. It is a combination of instruments (fig. 1) fastened to a beam, GBL; the *coulter*, K, is an iron knife-blade, for cutting the sod vertically; the *share*, CFD, which is merely a socket fitted on and not fastened to the body of the plough, has a sharp point, C, and a projecting horizontal edge, CO, on its right-hand side, its part of the work being to separate the under surface of the sod from the subsoil; by means of the *mould-board*, H, the slice, now wholly

separated from the firm ground, is raised up and turned over by the forward motion of the plough; and the *stilt*, or handles, one of which, BL, is a continuation of the beam, the other, M, being fastened partly to the former by rods, and partly

Fig. 1.

to the lower portion of the framework (fig. 2, which also shows the point of the plough with the share removed), are for the purpose of guiding the implement. The front part of the beam is formed with an upward curve; at its extremity is placed

Fig. 2.

the *bridle*, N, to which the horses are attached by means of swing-trees and chains or traces, and the object of which is to enable the workman to elevate or depress the line of draught, or move it to the right hand or the left, as may be found necessary. The left sides of the coulter, share, and framework ADEB should evidently be in the same vertical plane. The form of the mould-board is of the utmost importance, and has chiefly attracted the attention of agricultural machinists since the time when improvements on the plough were first projected. Its office being to raise and turn the sod, it is necessary that the surface should slope upwards and outwards from the front, so as to apply a pressure in both directions, and, accordingly, the surface is so shaped that from the point of the share, where it is horizontal, it gradually curves upwards, till, at the extremity, P, it inclines over away from the body of the plough. The gradual change produced on the position of the furrow-slice is seen in fig. 3, where ABCD on the left-hand side

Fig. 3.

represents the slice untouched by the plough, AD being the line of section by the coulter, DC by the share, BC the open side from which the previous furrow (E) to the right hand side has been separated, and the four successive rectangles, ABCD to the right, illustrate the successive changes of position of the furrow as the mould-board is pushed forward under and on its left side, till it is finally left, as represented in ABCD, on the right hand; E, F, G are furrows which have previously been laid in their proper position. The modern plough is wholly formed of iron, and in nearly all the English and several of the Scotch and Irish made ploughs wheels are attached at or

near the front end of the beam, a contrivance which renders the implement more steady in its motion, more easily managed, and capable of doing better work in the hands of an inferior workman. The usual dimensions of the furrow-slice in lea or hay-stubble are 8 or 9 inches in breadth by 6 in depth, and in land for green crop 10 or 11 inches in breadth, and 7 to 9 in depth. Shallower ploughing is not unfrequently adopted, especially on thin soils, and in various parts of England. Nor is it uncommon to plough stubble-land 10 inches or more in depth.

Other kinds of ploughs are used for special purposes, such as *trench-ploughs*, which are made on the same principle as the common plough, but larger and stronger, so as to bring up a portion of the subsoil to the surface; *subsoil ploughs*, some patterns of which have no mould-board, and merely stir and break up the subsoil, thus facilitating drainage; *double mould-board ploughs*, which are merely common ploughs with a mould-board on each side, and are employed for drilling turnip or potato land, for water-furrowing, and for earthing up potatoes; *turn-wrest ploughs*, which have the mould-board so arranged that in going in both directions the furrow is turned to the side; American *Chill ploughs*, which are exceptionally light in draught, go over the ground rapidly, and break up the surface soil more finely than the ordinary plough; the *double-furrow plough*, which turns two furrows at one operation, and which, although used on many farms, has not become so popular as was at one time expected. Of each of these ploughs there are many varieties, each maker having generally some peculiar views regarding the form and proportion of some parts of the instrument. For those who wish to study minutely the best form of plough it will be necessary to consult works on agriculture and agricultural implements.

The operation of ploughing can only be briefly referred to. Wherever the soil has been efficiently drained the ridges can be made wider and ploughed on the flat, high ridges being no longer necessary for carrying off the water. It is found in practice that the fewer the open furrows the better, particularly when the land is intended for a grain crop which is to be sown by drill or broadcast with machinery, and when the crop is to be cut with a binder, as is now almost universally the case. It is curious to notice how one improvement in farm practice leads on to another. The most common mode of ploughing with horses is now simply by casting the soil two ridges in and the next two out, beginning always with the two ridges where last time was left the open furrow.

The process of feering or commencing a ridge differs according to the state of the land to be turned over. If there exists an old furrow or hollow, as is generally the case in lea, two shallow furrows are turned, the one against the other, and so on; along each side of this commencement the plough moves, adding furrow after furrow, and increasing in depth until the third or fourth round is reached. This constitutes what is technically called the gathering system. In newly-cleaned land, or where a hollow does not appear to turn the first furrows into, two furrows are thrown out and then turned lightly in. The most common system, however, is what is known as *casting or clearing*. That is, after one feering is accomplished, another is made at the other side of the ridge, and furrow after furrow is turned towards the inside of each of these feerings until the whole ridge is ploughed, and then in the centre is formed the *finish* or *mids*—a furrow or trench into which the feering is turned the next time the land is ploughed.

The plough is one of the most ancient of imple-

ments, and is mentioned in the Old Testament at a very early period, iron shares being also incidentally noticed more than seven centuries B.C. Sir E. B. Tylor has in his *Anthropology* clearly shown how the plough arose by gradual development out of the hoe, and that out of the pick or hatchet.

Fig. 4.

1, Plough still used in Asia Minor; 2, its pole, where the oxen are attached; 3, shares of various forms; 4, the tail or handle; 5, the yoke; a, early Greek plough.

The fields of Sweden were formerly tilled with the 'hack,' of which specimens were still seen in the 19th century. The hack was simply a 'stake of spruce-fir with a bough sticking out at the lower end cut short and pointed.' This implement was gradually made heavier, and dragged by men through the ground, so as to make a simple furrow. Next it 'was made in two pieces, with

a handle for the ploughman and a pole for the men to drag by, the share was shod with an iron point, and at last a pair of cows or mares were yoked on instead of the men.' The development of the Egyptian plough was 'milar. The ancient Egyptian plough was wholly of wood, and in some instances consisted of little more than a pointed stick, which was forced into the ground as it was drawn forward; though there seem to have been ploughs with handles, and with metal socks. The earliest form of the Greek plough, the *antogyon* (fig. 4, a), was merely the trunk of a small tree, which had two branches opposite to each other, one branch forming the share and the other the handle, while the trunk formed the pole or beam. The more improved form, the *pekten*, in use among the Greeks, was not substantially different from the modern form in use in some parts of Asia Minor (fig. 4). The

Fig. 5.

drawn forward; though there seem to have been ploughs with handles, and with metal socks. The earliest form of the Greek plough, the *antogyon* (fig. 4, a), was merely the trunk of a small tree, which had two branches opposite to each other, one branch forming the share and the other the handle, while the trunk formed the pole or beam. The more improved form, the *pekten*, in use among the Greeks, was not substantially different from the modern form in use in some parts of Asia Minor (fig. 4). The

Fig. 6.

ancient Egyptian plough in one of its early stages is represented in fig. 5. The Romans, an essentially practical nation, largely improved on the

plough, adding to it the coulter and mould-board, and occasionally attaching wheels to the beam to prevent the share from going too deep into the earth (fig. 6). The plough was almost unknown among the American aborigines, though Prescott describes a mode of ploughing practised among the Peruvians, which consisted in the dragging for ward of a sharp-pointed stake by six or eight men, its sharp point, which was in front, being kept down in the ground by the pressure of the foot of another man who directed it. The ancient heavy plough dragged by eight oxen was still in use in Aberdeenshire well into the 18th century. In Britain the most important amendments on the plough are not two centuries old, and some of them were doubtless borrowed from the careful agriculture of Holland. England took the lead in improvement, followed some time later by Scotland, in which the chief improvers were James Small (the inventor of the Scottish *swing* plough), Wilkie, Gray, and Sellar. In England the improvers have chiefly been Ransome of Ipswich (the patentee in 1785 of the cast-iron share), Howard of Bedford, Hornsby of Grantham, and Busby of Bedale, the last of whom gained a medal for his mould-boards at the Great Exhibition of

the furrow-slice, decreasing friction, and saving labour to the ploughman, who has a seat on the implement; the disadvantage is the much greater cost of this kind of plough, and the cumbersome size. The Double Michigan plough has a small paring plough on the beam in front of the other; the small plough pares off the surface and throws it into the previous furrow, and the large one completely buries it under a heavy furrow-slice. Reversible ploughs, like the Oneonta Clipper, have the share and mould-board so that they can be easily changed from one side to the other; these are also called *swivel* ploughs or *side-hill* ploughs.

Steam-ploughing.—It has been alleged that the cultivation of the land by steam had been contemplated as far back as the 17th century. So long ago as 1618 David Ramsey and Thomas Wildgosse took out letters-patent for engines and machinery to plough the ground without the aid of oxen or horses, and the attempt has been made to show that steam was the motive power intended to be employed; but, as the first patent was taken out nearly forty years before the Marquis of Worcester described the steam-engine in his *Century of Inventions*, the grounds for such an opinion do not seem quite satisfactory. In 1769,

however, after the steam-engine had been applied to other purposes, there was lodged in the Patent Office a specification for a new machine or engine, to plough, harrow, and do every other branch of husbandry, without the aid of horses. The patentee was Francis Moore; and so confident was he of the merits of his plan that he sold all his own

Fig. 7.—Ransome's Wheel Plough.

1851. Ransome's wheel-plough has long finely-made mould-board, rather short broad share, straight coulter, and with the two wheels on level land can almost move unattended. Ancient types, however, still survive; the East Anglian plough has only one (wooden) stilt, and is very heavy, but makes good work. There are many specially American types of plough. In the 'Sulky' plough wheels support the weight of the plough and of

horses, and persuaded his friends to do the same; 'because the price of that noble and useful animal will be so affected by the new invention that its value will not be one-fourth of what it is at present.' Moore, like many who followed in his wake, was much too sanguine. The truth is that even yet steam-power has only to a very small extent supplanted horse labour in the cultivation of the soil. Early English patentees were Pratt in 1810, and

Fig. 8.—Fowler's Anchor, Engine, and Plough at work.

Heathcote in 1832. But the first steam cultivating apparatus which gave anything like satisfactory promise of success was that for which Messrs Fiskien of Stamfordham, Newcastle-upon-Tyne, took out a patent in 1855. Mr Fowler of Leeds, and Messrs Howard of Bedford, and others followed with apparatuses of various patterns. The different inventions brought into notice from time to time have included plans for engines travelling over the surface of the ground, drawing ploughs or other cultivating implements along with them; engines working on tramways and

drawing implements after them; engines moving along opposite headlands, and working implements between them by means of wire-ropes, and stationary engines driving implements also by means of wire-ropes. Only two of these systems got beyond the experimental stage. These are what are called the direct and round-about—the former where the pull of the implement is directly to and from the engine, or between two engines, one at each end of the furrow; and the latter where the implement is drawn at right angles. The best known of the apparatuses now in use are

those made by Fowler, Howard, and Barford and Perkins, of Peterborough.

The ploughs used in the various systems are very similar in construction, some taking four and others six furrows at each time. Fowler's apparatus is shown at work in figs. 8 and 9.

It has to be noted, however, that, with all the ingenuity and capital expended on the perfecting of the appliances, steam-power has not been employed in the cultivation of the soil anything like so advantageously or extensively as was at one time expected by the advocates of the practice. The great agricultural depression following the disastrous year of 1879 gave the system its first serious check. The injury unwittingly done to large extents of land by excessively deep ploughing—

Fig. 9. —Fowler's Plough.

by burying the good soil and bringing bad material to the surface—also tended to discredit steam-cultivation. It has as a rule been found in practice that moderate ploughing and deep stirring are preferable to deep ploughing, and steam-power is now more largely employed in stirring and harrowing the soil than in turning it over in furrows. Upon extensive farms, where the fields are large and conveniently shaped, steam-tillage may be pursued with excellent results if the farmer is careful to adapt the operations to the particular character of the soil. In recent years great progress has been made in the adaptation of oil-tractors to ploughing and other operations of cultivation. The tractors vary from 15 to 40 horse-power, and draw two, three, or four furrow ploughs. Many of the tractor-plough combinations now available do excellent work.

See J. R. Bond, *Farm Implements and Machinery* (1925); *Standard Encyclopedia of Modern Agriculture* (1911); also works on agriculture by Frean, Webb, and Wrightson.

Ploughgate, in the law of Scotland, is an expression denoting a quantity of land of the extent of 100 acres Scots. See CARUCATE.

Plough-Monday, or PLOW-MONDAY, the Monday after Twelfth Day, and termination of the Christmas holidays, when, according to the old usage, the plough should be set to work again. On Plough-Monday ploughmen were wont to drag a plough from door to door, begging money for the usual antics and ruder festivities.

Plover, a name given to numerous species of birds belonging to several genera of the family Charadriidae. They have a straight compressed bill, but the upper jaw is slightly inflated and slightly bent at the point; the nasal groove extends about two-thirds of the length of the bill, the nostrils are longitudinally cleft near the base; the legs, which are not very long, are naked a little above the tarsal joint; with one exception there is no hind-toe; the wings are rather long and pointed, the first quill-feather is the longest. The species are numerous, and are found

in every quarter of the globe; many of them are birds of passage. They chiefly frequent low, moist grounds, where they congregate in large flocks, and feed on worms, molluscs, insects, &c.; but some of them visit mountainous regions in the breeding season. They fly with great strength and rapidity, and run with much swiftness. The flesh and eggs of many of them are esteemed delicacies. A common British species is the Golden Plover (*Charadrius plumbeus*), a handsome bird, of a blackish colour, speckled with yellow at the tips and edges of the feathers; the throat, breast, and belly black in summer, whitish in winter. The golden plover is a bird of passage, visiting in summer the northern parts of Europe, of the west of Asia, and of North America, and

migrating to the south in winter. It is known in most parts of Europe, and is common in many districts of Britain, breeding in the northern counties. Great numbers frequent the sandy pastures and shores of the Hebrides and of the Orkney and Shetland Islands. It makes an artless nest, little more than a slight depression in the ground, and lays four eggs. The parent birds show great anxiety

for the protection of their young, and use various stratagems to divert the attention of an enemy. The golden plover exhibits great restlessness on the approach of wet and stormy weather, whence its specific name *plumbeus*.

The Ringed Plover (*Agriolitis hiaticula*), locally called Stone-hatch or Sand-lark, a much smaller bird, not so long as a song thrush, is found at almost all seasons on the shores of the British Islands, frequenting sandy and shingly flats, from which the sea retires at ebb-tide. It is often to be seen

1, Ringed Plover; 2, Gray Plover; 3, Golden Plover.

also on the banks of large rivers, and not unfrequently by lakes and ponds. It is found in most of the northern parts of Europe and Asia, and in Iceland and Greenland. It is grayish brown above, whitish beneath, with a collar of white round the neck, and below it a black—in winter a brown—collar; the head marked with black and white; a white bar on the wing. Very similar, but smaller, and with an incomplete collar, is the Kentish Plover (*Æ. cantiana*); and also similar in form and habits is the smallest of the British species, the Little Ringed Plover (*Æ. curvica*). Both of these are rare in Britain. The Gray Plover (*Squatarola helvetica*), a species somewhat larger than the golden plover, is distinguished by black axillaries, white tail-coverts, and the presence of a hind-toe. North America has a number of species

of plovers, such as the Kildeer Plover (*A. vocifera*), abundant on the great western prairies, and not unfrequent in the Atlantic states. It utters, when approached by man, a querulous or plaintive cry, like the lapwing, the Green Plover. See DOTTEREL, and LAPWING; and for the so-called Stilt Plover, see STILT.

Plover's eggs are sold in enormous quantities in London and other large towns, and command an extraordinary price, eighteen shillings a dozen or even more, being sometimes given for them, and the cost is seldom less than threepence or sixpence per egg. These are supposed all to be plover's eggs, or, really, lapwing's eggs; but doubtless the eggs of many other birds are substituted, those of the red-shank being very similar in appearance and flavour. Rook's eggs are too decidedly unlike the plover's to be put in their place. Some sea-birds' eggs are occasionally passed off under the name; and it is said that eggs outwardly unlike plover's have been skilfully painted by hand in order to deceive. Scotland, Ireland, and Holland are all laid under contribution to produce the tens of thousands of dozens of genuine plover's eggs which it is computed are annually consumed in London.

Plum, the fruit of several trees of the genus *Prunus* (family Rosaceæ), especially of *P. domestica*. By long cultivation various garden forms have been produced, but it is impossible to trace the line of descent in every case. Blackthorn, or Sloe (q.v.), and the Bullace (q.v.) are both British plants. The Wild Plum (*P. communis* or *P. domestica*) also occurs, but is not indigenous. Some would group all three as varieties of one species. The Mussel and the Wine Sour, which are used in cooking and in confectionery, are regarded as primary varieties of the wild plum. The cultivated varieties of the plum are very numerous; there are larger and smaller kinds, but their value in the dessert is reckoned by their sweetness and flavour rather than by their size. Thus, the Green Gage, a kind with only moderate-sized fruit, is the most esteemed of all. It is the *Reine Claude* of the French, and the *Regina Claudio* of the Italians. *Magnum Bonum*, a very large white variety, though one of the handsomest, is accounted only of second-rate quality. *Prunes* are the dried fruit of certain kinds of plum. The finest of all the French prunes are made at Brignole in Provence of the varieties of plum called *Pedrigon blanc* and *Pedrigon violet*, which are hence named *Pruneaux de Brignole* or *Brignoles*. The manner of converting these plums into prunes is by drying in a slow oven. The fruit is allowed to remain on the tree till it is so ripe that a little shaking would cause it to fall. They are then carefully picked and spread out in the sun on sieves made of lath or wickerwork till they become soft. Afterwards they are put in a spent oven, and shut up close in it for twenty-four hours, and then taken out. The oven is again heated, somewhat warmer than before, and the plums returned to it till the following day, when they are taken out and turned by slightly shaking the sieve. Again the oven is heated, rather warmer than before, and the fruit returned to it for twenty-four hours, and so on till the operation of drying is finished, a point which only experience can nicely determine. Prunes of inferior quality are made from the fruit of the *Petit Domes*, and from the *Quetsche*, the latter being made in Germany. From this also is distilled a kind of brandy. In Bosnia and Herzegovina vast quantities of prunes are produced in a good season. Prunes are nutritious and laxative, and stewed in water are excellent diet in case of costiveness and during convalescence from fevers and inflammatory complaints. They impart their laxative quality to the water in

which they have been stewed. The plum is grown in orchards as standard and bush trees, or in the case of the choicer varieties trained to walls. It is not fastidious as to soil, but the finest fruit is produced on strong but well-drained loam. The superior kinds are propagated chiefly by budding and by grafting, the inferior by layers or by cuttings of the roots, the latter being a common method in rearing Damsons in some parts; but the quickest and best method of increasing all is by budding. The wood of the plum-tree is hard and fine-grained, and is used in cabinet-work and in turnery. The Kashmir Plum, cultivated in Kashmir and Bokhara, is identical with *P. insititia*. The Cherry Plum, or Myrobalan Plum (*P. divaricata*), is a bush very similar to the sloe, with pendulous globular red fruit. It is of oriental origin, but is often cultivated for its fruit on the continent of Europe. In Britain it seldom produces fruit. *P. maritima* is a shrub, indigenous to sandy soils on the seacoast of North America from Massachusetts to Alabama. It has a dark-purple agreeable fruit, about the size of a pigeon's egg. Other native American species are *P. angustifolia*, the Chickasaw Plum, a shrub or small tree of the southern states; *P. americana*, a bushy tree ranging from Canada to Georgia; and *P. glandulosa*, of Texas, which is less than a foot high, and has crooked thorny branches. The genus *Prunus* has about 130 species (50 in China). See also APRICOT, CHERRY, PEACH.

The Cocoa Plum or Icacó of the West Indies is the fruit of *Chrysobalanus icaco*, a tree of the family Rosaceæ, sub-family Chrysobalanoidæ. The fruit resembles a plum, has a sweet although slightly austere taste, and is eaten both raw and preserved. The fruit of *Parinarium excelsum*, another of the Chrysobalanoidæ, is called the Gray Plum in Sierra Leone.—The term plum is used loosely for the Date Plum (q.v.); and plum or plumb was a word once current for £100,000.

Plumage. See BIRD, and FEATHERS.

Plumbaginæ, or PLUMBAGINACEÆ, a family of dicotyledons, herbaceous or half-shrubby, to which belong about 300 known species, chiefly found on the seashores and in the salt marshes of temperate regions. Some are found also in elevated regions in all zones. Many have flowers of great beauty, and are therefore favorites in gardens. Some are occasionally used in medicine as tonics and astringents; others, being exceedingly acid, as vesicants, particularly species of *Plumbago*. Thrift, or Sea-pink (q.v.), is the most familiar British example of the family. Sea-lavender (*Statice limonium*), an inhabitant of the coasts of England and (rather rarely of Scotland), common, however, on the western coasts of Europe, the Mediterranean, and western Asia, appearing also on the seashore of South America and of the Carolinas, and there known by the name 'Marsh Rosemary,' is extremely bitter and astringent. Its most abundant principle is tannic acid, of which it contains 12·4 per cent. Along with this it gives a peculiar gum and extractive volatile oil, resin, caoutchouc, colouring matter, lignin, and various salts.

Plumbago. See BLACK-LEAD, PLUMBAGINEÆ.

Plumbism, or LEAD-POISONING. See LEAD.

Plume-bird, a term sometimes given to the Epimachidae or Long-tailed Birds of Paradise (q.v.).

Plumer, HERBERT CHARLES ONSLOW PLUMER, BARON, born 13th March 1857, served in Sudan (1884) and South Africa. In the Great War he commanded the Fifth Army Corps in France (January-May 1915), the Second Army (1915-17),

the Expeditionary Force in Italy (1917-18), and in the closing stages of the war the Second Army again. He was made governor of Malta, field marshal, and a baron in 1919, high commissioner for Palestine in 1925. See WAR (GREAT).

Plummer's Pills. See GUAIACUM.

Plumptre, EDWARD HAYES, was born in London, 6th August 1821, and educated privately and at University College, Oxford, graduating with a double first-class in 1844. The same year he was elected fellow of Brasenose College. He became chaplain at King's College, London, in 1847, and afterwards professor of New Testament Exegesis there. In 1863 he was given a prebend of St Paul's, and from 1875 to 1877 he was principal of Queen's College, Harley Street. He was select preacher at both universities, Boyle Lecturer in 1866-67, and one of the Old Testament Company for the Revision of the Bible. In 1869 he was presented to the rectory of Pluckley in Kent, which four years after he exchanged for the vicarage of Bickley, and in 1881 he was installed Dean of Wells. He died 1st February 1891. In *The Spirits in Prison* (1884) he spoke out eloquently his belief in the 'wider hope' and an intermediate state of probation. He published several volumes of sermons and studies, contributed to various commentaries, to Smith's Dictionaries, and to periodicals. His name is also widely known by his admirable verse translations of *Sophocles* (1865), *Æschylus* (1868), and the *Commedia* of Dante in the original metres (1886); as well as by several volumes of original verse. His *Life and Letters of Bishop Ken* (1886) is less happy.

Plum-pudding. This national English dish is an example of the happy results of the law of evolution. The 'plumb-porridge' which delighted our ancestors has been drained and dried and squeezed into the moulds of civilisation, and few will doubt the 'survival of the fittest' among its ingredients. It is not known when the change from porridge to pudding actually took place. In *Hudibras* we find a mention of 'minced pies and plumb-porridge.' Addison in the *Tatler* speaks of both as the 'first parts of the dinner'; and in the *Spectator*, No. 269, plumb-porridge is mentioned as eaten on Christmas Day. Southey in his *Omnia*, vol. i. p. 7, quotes a recipe for plum-pudding as given in French by the Chevalier d'Arviens, who in 1658 made a voyage in an English forty-gun ship. This pudding was directed to be boiled in meat broth, and when dished up to be covered with grated cheese. In the earlier collections of recipes we find nothing of the kind, unless a hint of plum-porridge be discerned in the mixture called *Rape*, a *passet* of 'raisins of corans' with 'sweet wyne' and 'crustes of bred.' A recipe for this is given in *A Noble Poke off Cookry* (ed. Napier, p. 109), which must have been written out in the 15th century, but was then probably copied from one of a much earlier date.

Plumstead. See ERTH.

Plumularia, a genus of Hydrozoa (q.v.), typical of the family Plumulariidae, which includes about a fourth of all the hydroid zoophytes.

Plumule. See SEED.

Pluralism. Persons in power have often added to their wealth and consequence by holding several appointments; but such pluralism is forbidden by the constitutional practice of many modern states. In England a minister who holds two political offices (e.g. those of First Lord of the Treasury and Chancellor of the Exchequer) receives only half the salary of the second. Pluralism in the church has been held unlawful from the earliest times, and is forbidden by many ancient councils,

as Chalcedon (451 A.D.), 2d Nicea (787 A.D.). This prohibition, however, was not regarded as absolute; canonists distinguish 'compatible' and 'incompatible' benefices or dignities. Two benefices may be incompatible in three ways—(1) if each requires residence; (2) if the duties of both fall to be discharged at one and the same time; or (3) if the revenue of either fully suffices for the becoming maintenance of the incumbent. In other cases benefices or dignities are considered compatible, and with the due dispensation, granted by the pope, may be held by the same person. In England the law of the church has been made more stringent by acts of parliament passed in 1837, 1850, and 1885. The effect of these acts seems to be that no person can now hold two benefices unless the churches are within two miles of each other and one of them is not worth more than £200 a year. A benefice of 3,000 population is not to be held along with a benefice of 500 population. In order to hold two benefices a clergyman must obtain a dispensation from the Archbishop of Canterbury. Acceptance of a second preferment, except in the cases provided for in the acts, will vacate any preferment previously held. In Scotland it is contrary to the statute of 1581 for a minister of the Established Church to hold two or more charges, and the rule has been regularly enforced in the case of two pastoral charges. In the case of ministers appointed professors before or after an appointment to a pastoral charge, a resignation is now necessary of one of the offices within a certain time after the appointment.—Pluralism, in philosophy, is opposed to absolutism and monism, and insists on the reality of finite individuals. It may either content itself with accepting a plurality, of self-existent conscious beings as the ultimate facts of the universe, asserting the impossibility of including them in any higher unity; or with Professor Ward attempt to reunite pluralism with creation and tæism. William James was a conspicuous exponent of pluralism. See LEIBNIZ.

Plush (Fr. *peluche*), a variety of cloth woven like velvet, but differing from it in having a longer and more open pile. Formerly this pile was of goat's hair or worsted, but now it is largely made of silk, with a cotton backing, and sometimes the whole fabric is of silk. Silk plush is the material used for the outside of gentlemen's 'silk' hats, and is called hatter's plush. It is also worked in coloured silks for articles of ladies' attire and for covering furniture; but plush is used *par excellence* for livery knee-breeches.

Plutarch (*Ploutarchos*), a prolific writer of the Greco-Roman period, was born about 46 A.D. at Chieroneia in Boeotia, where his family was one of good standing. Nothing is known of his personal history but what may be gathered from his own writings. His higher education was commenced at Athens under the academic philosopher Ammonius in 66, the year of the Emperor Nero's progress through Greece. He paid more than one visit to Rome, the then metropolis of the world—on the first occasion in the reign of Vespasian as *chargé d'affaires* of his native town. There he enjoyed the friendship of several men of mark, such as Gaius Sossius Senecio, who was four times consul, while he devoted himself to a course of study and gave public lectures in philosophy, so that he had but little leisure left for learning the Latin language, and never attained a full knowledge of its niceties and idioms or a correct notion of Roman institutions. The story that he became Trajan's preceptor, and was raised by that emperor to the consulship is a legend of doubtful credit. Life at Rome, however, was not altogether to his taste; he preferred the quiet of his native place,

and there he spent all his mature life until his death about 120, discharging the civil and religious duties which fell to his station, liberally disbursing his stores of learning, and offering himself as a sort of spiritual guide and physician of the soul to those who needed moral hygiene and desired to rule their lives by some higher standard in a corrupt and effete age, when the old faiths were dead and the objects of modern life as yet below the horizon. The extant writings of Plutarch fall into two principal classes—(a) his historical works, (b) those which are grouped under the general head of *Opera Moralia* (*ἠθικά*). To the former belong his *Parallel Lives*—the work by which he is best known. These contain a gallery of portraits of the great characters of the ages preceding his own. They were published in successive books, each pair forming one book (*bibliōn*), a Greek and Roman, with some resemblance between their respective careers, being chosen for the subject of each. The forty-six extant *Lives* were contained in twenty-two books, probably in the following sequence (that in which they are usually arranged being purely arbitrary): (2) *Sertorius—Eumenes*, (3) *Cimon—Lucullus*, (4) *Lysander—Sulla*, (5) *Demosthenes—Cicero*, (6) *Agis and Cleomenes—Gracchi*, (7) *Pelopidas—Marcellus*, (8) *Phocion—Cato mi.*, (9) *Aristides—Cato mi.*, (10) *Pericles—Fabius Maximus*, (11) *Nicias—Crassus*, (12) *Dion—Brutus*, (13) *Timoleon—Æmilius Paulus*, (14) *Philopœmen—Titus Flamininus*, (15) *Themistocles—Camillus*, (16) *Alcander—Cæsar*, (17) *Agésilas—Pompeius*, (18) *Pyrrhus—Marcus*, (19) *Solon—Valerius Publicola*, (20) *Demetrius—Antonius*, (21) *Alciades—Coriolanus*, (22) *Theseus—Romulus*, (23) *Lycurgus—Numa*. The first series, which includes (2) to (9), was written at the suggestion of some personal friends. The biographies in this series partake more of a historical than of an ethical character. The second, (10) to (19), was composed for the writer's own satisfaction and moral improvement; the third, (20) and (21), professed to teach virtue by painting its opposite; the fourth, (22) and (23), dealt with prehistoric characters. The single biographies of *Arcitus*, *Artaxerxes*, *Galba*, and *Otho* do not come under the category of *Parallel Lives*. The sequels which come after most of the *Lives*, giving a detailed comparison (*synkrisis*) of each warrior, statesman, legislator, or hero, as the case may be, and of the exact points of resemblance between them, hardly accord with the design of Plutarch, and are therefore regarded as spurious by some critics.

Plutarch's biographies are not merely popular compilations, but monuments of great literary value for the precious materials which they contain, based as they are upon lost records. The author adheres throughout to his professed purpose—viz. portraiture of character; he either omits or briefly touches upon the most famous actions or events which distinguish the career of each subject of his biography, holding that these do not show a man's virtues or failings so well as some trifling incident, word, or jest. 'C'est la vérité morale,' says Gréard, 'non la vérité historique, qu'il poursuit; l'une n'est pour lui que le moyen, l'autre est le but.' For this reason the *Parallel Lives* are and will remain the book of all ages, for no book of classical antiquity has had more influence upon the leading men of the world, so that Plutarch may almost be called the interpreter of Greece and Rome to modern Europe. They form indeed a complement to the other and less known half of his writings—the *Morals*—a collection of short treatises, sixty or more (though certainly not all from Plutarch's hand), upon various subjects—*Ethics*, *Politics*, *History*, *Health*, *Fæctia*, *Love-stories*, and *Philosophy*. The last comprise

dissertations *On the nature of the unseen world and spiritual beings*, *On the creation and government of the Universe*, *On the human soul*, and similar speculations, classed by the ancients under the head of *Theosophy*. 'The treatise upon *Isis and Osiris* in this series,' says C. W. King, who revised Holland's translation in 1882-88, is 'the only complete account of the religion of Egypt that has come down to us—written too by one who had been initiated in its deepest mysteries. The three treatises upon the *Oracles* also are of the highest value, and that on *Superstition* is one of the most eloquent and closely reasoned compositions of antiquity.' Some of the essays, especially those *On Brotherly Love*, *On gradual advance in virtue*, *On the benefit to be got out of enemies*, breathe quite a Christian spirit, although the writer probably never heard of Christianity or its divine founder. One of the most interesting is that *On the apparent delays in divine justice*; another, *On the conduct proper to young men at Lectures*, which is partly moral, partly social in its tone. The nine books of his *Symposiaca* or Table-talk on a variety of topics exhibit him in the light of the most amiable and genial of boon companions, who appreciated good conversation; while his dialogue *Gryllus* reveals a remarkable sense of humour.

Though not a profound thinker, Plutarch was a man of rare gifts, and occupies quite a unique place in literature as the encyclopedist of antiquity. He was not master of any science, but whatever was noticeable in natural, moral, or metaphysical science did not come amiss to him, and he had a universal sympathy with genius and nobility of character. As a moralist he is, as Professor Mahaffy well describes him, the spokesman of the better life that still survived in the Greek world in the 'Marthamas summer' of its history; not the exponent of any system, and only occasionally an opponent, as in the *Dialogue against Colotes*, the disciple of Epicurus, and that *Against the Stoic first conceptions*, but a man of practical views and sober judgment, a chief example of the illumination of the intellect by the power of morals. His kindly sympathy and tender-heartedness, a leading feature in his character, is well shown in his *Consolation addressed to Apollonius on the early death of his son*, and the beautiful *Letter to his wife on the death of their only daughter*. As a stylist he is picturesque, realistic and varied; his chief fault is a tendency to diffuseness and redundancy of expression. He does not, like his contemporary Lucian, affect the Attic purity and clearness of diction, and he is too fond of crowding his sentences; but occasionally he rises into eloquence, and he is almost always happy in the novelty of his illustrations and similes and the point of his anecdotes.

The best editions of Plutarch's entire works are those of J. J. Reiske (12 vols. 1774-79) and Dübner-Dohner in Dido's *Bibliotheca* (5 vols. 1846-55). The best text of the *Lives* is that of Sintenis in the Teubner series (5 vols. 1874-81); that of the *Moralia*, that of D. Wytenbach (15 vols. Oxford, 1795-1830; unfinished), and that in the Teubner series by G. N. Bernardakis (6 vols. 1888-95). There are translations of the *Lives* in English by the brothers Langhorne and by Dryden and others (the latter re-edited by A. H. Clough, 5 vols. 1874)—neither so scholar-like and correct as the French of Jacques Amyot (Paris, 1559), from which Sir Thomas North's version (1579; now ed. by Wyndham, 6 vols. 1895 et seq.) was made; also (with text) by R. Perrin (11 vols. 1914 et seq.), and of the *Roman Lives* by G. Long. A translation of the *Moralia* by several hands was revised by W. W. Goodwin (1874-78). See Trench's lectures and Octave Gréard's study: *Oakesmith's Religion of Plutarch* (1902); Dill's *Roman Society from Nero to Marcus Aurelius* (1905); Mahaffy's *Silver Age of the Greek World* (1911); Miss Westaway's *Educational Theory of Plutarch* (1922); and H. J. Rose's translation, &c., of *The Roman Questions* (1924).

Pluto (Gr. *Ploutón*, from *ploutein*, 'to be rich'), originally only a surname of Hades, as the giver or possessor of riches is, in the mythology of Greece, the third son of Kronos and Rhea, and the brother of Zeus and Poseidon. On the tripartite division of the universe he obtained the sovereignty of the under-world—the realm of darkness and ghostly shades, where he sits enthroned as a 'subterranean Zeus'—to use the expression of Homer, and rules the spirits of the dead. His dwelling-place, however, is not far from the surface of the earth. Pluto is inexorable in disposition, not to be moved either by prayers or flatteries. He is borne on a car, drawn by four black steeds, whom he guides with golden reins. His helmet makes him invisible. According to some scholars, his name of *Hades* is from *α priv.*, and *idein*, 'to see;' although others, with less probability, derive *Hades* from *hadō* or *chadō*, 'I receive or embrace,' and translate the word the 'all-receiver.' In Homer *Hades* never means a place, but always a person. Moreover, it is to be noticed that the poet does not divide the realm of the shades into two separate regions. All the souls of the dead—good and bad alike—mingle together. Subsequently, however, when the ethical conception of future retribution became more widely developed, the kingdom of the dead was divided into Elysium (q.v.), the abode of the good, and Tartarus (q.v.), the place of the wicked. This change also exercised an important influence on the conception of Pluto. The ruler of the under-world not only acquired additional power and majesty, but the very idea of his character was essentially modified. He was now regarded as a beneficent deity, who held the keys of the earth in his hand, and possessed its metallic treasures (whence his new name *Pluto* or *Plutus*), and who blessed the year with fruits, for out of the darkness-underground come all the riches and swelling fullness of the soil. Hence, in later times, mortals prayed to him before proceeding to dig for the wealth hidden in the bowels of the earth.

Pluto married Persephone (Proserpina), the daughter of Demeter (Ceres), after carrying her off from the plains of Enna. He assisted his brothers—according to the mythological story—in their wars against the Titans, and received from the Cyclopes, as a reward for delivering them from Tartarus, the helmet that makes him invisible, which he lent to Hermes (Mercury) in the afore-said war, to Perseus in his combat with the Gorgons, and which ultimately came to Medusa. The Erinyes and Charon obey his behests. He sits in judgment on every open and secret act, and is assisted by three subordinate judges, *Aeacus*, *Minos*, and *Rhadamanthus*. At Elis alone was there a formal cult of Pluto, though in many places in Greece he was worshipped conjointly with Demeter and Kore. Among trees and flowers the cypress, boxwood, narcissus, and maidenhair were sacred to him; black rams and ewes were sacrificed to him amid the shadows of night, and his priests had their brows garlanded with cypress wreaths. In works of art he resembles his brothers Zeus and Poseidon; only his hair hangs down somewhat wildly and fiercely over his brow, and his appearance, though majestic, as becomes so mightily a god, has something gloomy and terrible about it.—The Plutonian theory in Geology, otherwise called Vulcanist or Huttonian, was opposed to the Neptunist or Wernerian. See GEOLOGY and HUTTON; and for the Plutonic rocks, see IGNEOUS ROCKS.

Pluviometer. See RAIN-GAUGE.

Plymouth, one of the most famous of English seaports, an ancient parliamentary, municipal, and county borough, and an important naval base, lies

in the extreme south-western corner of Devonshire, 230 miles by rail (216 by road) WSW. of London, 128 SW. of Bristol, and 44 SW. of Exeter. It occupies the northern shore of Plymouth Sound (see below), immediately at the mouth of the Plym. The remaining space between it and the Hamoaze, the estuary of the Tamar, is occupied by the smaller town of Stonehouse, while still farther to the west, along the Hamoaze itself, stretches the third of the 'Three Towns,' Devonport. Since 1914, however, Devonport and Stonehouse have formed part of Plymouth. Plymouth itself is the chief seat of commerce, trade, and manufacture, and within the 19th century displayed an enterprise which gave it a high place among provincial centres. The site is

a very fine one. Between the two natural inlet harbours of Sutton Pool and Mill Bay stretches the bold rocky ridge of the Plymouth Hoe, the eastern end of which is occupied by a citadel built by Charles II. Northward the ground rises in a series of long hills, along which the town stretches until it passes into a suburban hill of singular attractiveness. From the Hoe there are magnificent views both seaward and landward. On the Hoe, now laid out with grassy slopes and a promenade, the captains of the fleet which assembled to meet the Armada whiled away the time, according to tradition, by playing a game of bowls; and here stand a tercentenary memorial to the Armada heroes (1890), a statue (1884) of Sir Francis Drake (one of Boehm's finest works), the upper portion of Smeaton's Eddystone lighthouse, rebuilt here in 1882-84, and the Royal Naval War Memorial (1924). Old Plymouth—a dingy, unattractive set of narrow streets, chiefly clustered round the shores of Sutton Pool—is gradually disappearing, and the town now has miles of excellent thoroughfares and many handsome buildings, chief among them a noble Gothic guildhall (1874), with a series of stained-glass windows depicting episodes in the town's history. The principal antiquity is the fine 15th-century church of St Andrew, Perpendicular in style, and restored in 1874-75 by Sir Gilbert Scott; Charles Church, built with interruptions between 1640 and 1656, is a singularly good example of post-Reformation Gothic; the church of Stoke Damarel has an ancient tower (1490); while the Roman Catholic cathedral is an effective Early English edifice (1858). The Cottonian collection of sketches by the leading Continental masters is

at the Municipal Museum (1910), which also has important natural history and entomological collections; there is a good local museum at the Athenæum. There are numerous charitable institutions and hospitals. The Marine Biological Laboratory (1888), on Citadel Hill, is an important research centre. The town is served by the Great Western and the Southern Railway. In Millbay are the Great Western Docks, the property of the Great Western Dock Company, which are capable of taking the largest merchant-vessels. Sutton Pool, the ancient tidal harbour of Plymouth, in addition to a large general trade, is the seat of the fisheries of the port, which are very important. Manufactures, mainly chemical, are carried on—at Cattewater chiefly. There is a large foreign and a very extensive coasting trade, and the port is used by lines of passenger and mail steamers to almost every quarter of the globe. The chief government establishments are at Devonport—the South Yard (Royal Devonport Dockyard), established there by William III. in 1689; the North Yard (Keyham Steam Yard), founded at Morice Town in 1844; the Gun Wharf (1718), the Royal Naval Barracks (1886), Royal Naval College, a military hospital. Stonehouse, once called Hepeston, has a naval hospital, marine barracks, and the Royal William Victualling Yard, containing a naval ordnance depot. There is some trade in timber.

Though only a fishing-village at the Conquest, under the name of Sutton, i.e. South Town, Plymouth (so called since its incorporation in 1439 by Henry VI.) has for centuries played a leading part in nautical life. It was the favourite port of the Black Prince; the chief Elizabethan rendezvous of Drake, Hawkins, Grenville, Raleigh, and their fellows; the final port of departure of the *Mayflower* with the Pilgrim Fathers. In the civil wars it sided with the parliament, successfully enduring sieges and blockades for over four years, and it was also the first town to declare for William of Orange. In the great French war it rivalled Portsmouth in naval activities. Throughout its history the town has been several times sacked by coast marauders. Among its more distinguished natives are Sir John Hawkins, Sir Richard Hawkins, Sir Thomas Edmonds, Joseph Glanville, R. S. Hawker, Lord Monkswell, Sir W. Snow Harris, F.R.S., W. Elford Leach, F.R.S., with Northcote, Haydon, S. Prout, Sir C. Eastlake, P.R.A., and S. Hart, the artists. Plymouth (comprising the three parliamentary divisions of Drake, Sutton, and Devonport) returns three members to parliament. Pop. (1801) 43,194; (1871) 70,091; (1891) 88,931; (1911) 112,030; (1921) 209,857.

PLYMOUTH SOUND, on the south-west of Devonshire, near the entrance of the English Channel, is one of the famous roadsteads of the world. It is a deep inlet, into which the river Tamar falls from the west, and the river Plym from the east. The extreme seaward boundaries of the bay, from which the Sound, properly so called, opens, are Rame Head (mentioned in Ptolemy) and Stoke Point, not far within which a third river, the Yealm, debouches. The Sound, however, is practically bounded southward by a line drawn from Penlee to Wembury Points, and northward by the Plymouth Hoe. Within these limits its width varies from 2½ to 3 miles, while its landward depth is about 3. Immediately within Penlee Point, on the western side, is Cawsand Bay, formerly one of the chief anchorages of the port and navy, but so exposed to the south-easterly gales that it was at times very dangerous. Vessels anchored in the Sound itself were so open to the full fury of the south-westerly that in 1812 the construction of the Plymouth Breakwater was begun (see BREAKWATER). About half a mile from the Hoe is a little islet, originally called St Nicholas Island,

but now more commonly Drake's Island. A formidable stone fort has also been built on an artificial island immediately within the breakwater; while on either shore there are extensive forts and batteries—at Bovisand and Stamford on the east, and at Picklecombe, Maker, and Tregantle on the west. The estuary of the Plym is called the Cattewater, and is a capacious and important inner mercantile anchorage, opening from the Sound eastward, and protected by the Batten breakwater. The estuary of the Tamar is called the Hamoaze, and from the spot at which it enters the Sound between Devil's Point and Mount Edgembe to Saltash is nearly 4 miles in length—a still more valuable and thoroughly protected anchorage for vessels of the largest size, and occupied by men-of-war. In the Channel, 14 miles off the Sound, is the dangerous Reef of Eddystone (q.v.), indicated since 1698 by lighthouses, and now rather a directing post to the port than a danger. Plymouth Sound is exceedingly beautiful, and has even been considered worthy of rivalry with the Bay of Naples. On its western shore is Mount Edgembe, the delightful seat of the Earl of Mount Edgembe, traditionally said to have been selected by Melina Sidonia as his share of the English spoil. Rame Head, crowned by the ruins of a mediæval chapel, is one of the most picturesque headlands on the coast; and the estuary of the Yealm, with the peaked Mewstone at its mouth, is full of romantic beauty.

Plymouth. (1) capital of Plymouth county, Massachusetts, on Plymouth Bay, 37 miles by rail S.E. of Boston, is famous as the landing place of the Pilgrim Fathers (q.v.). Plymouth Rock is a granite boulder at the water's edge on which they landed. It is covered by a handsome granite canopy, and there is also a national monument (1858-89) to the pilgrims; the pedestal, also of granite, stands on a hill overlooking the landing-place, and is 46 feet high, surmounted by a central figure of Faith, 36 feet high, with four immense stone figures representing Morality, Education, Freedom, and Law around the base. In Pilgrim Hall (1824-25) are preserved many relics of the first settlement of the country. The town manufactures cordage, woollens, nails, tacks. It is popular as a summer resort. Pop. 13,000.—(2) A mining town of Pennsylvania, on the Susquehanna River, 20 miles by rail S.W. of Scranton. Pop. 16,500, largely foreigners.—(3) The capital of Montserrat (q.v.).

Plymouth Brethren, a name given by others to a body of Christians which since 1830 has extended itself throughout the British dominions and in some parts of the continent of Europe, particularly among the Protestants of France, Switzerland, and Italy, and also in the United States of America. It originated in a reaction against exclusive High Church principles, as maintained in the Church of England, with everything of a kindred nature in other churches, and against a dead formalism associated with 'unevangelical' doctrine. Some of the first members of the new religious communities formed in Plymouth and elsewhere were retired Anglo-Indian officers, men of unquestionable zeal and piety; but these communities began to appear almost simultaneously in a number of places. Their origin is, however, very much to be ascribed to the labours and influence of John Nelson Darby (1800-82), from whom the Plymouth Brethren on the continent of Europe are very generally known as *Darbyites*. Darby was a barrister, who under deeply religious impressions became a clergyman of the Church of England, and served as a curate in Wicklow; but in 1827 he left the Church of England from conscientious scruples, and became an evangelist unconnected with any church. In

this character he laboured both in England and on the continent of Europe, preaching in French, English, and German. It was in 1830 that he founded at Plymouth the congregation whence comes the name usually given to the communion; the Dublin assembly dates from the same year. He also gave utterance to his opinions in numerous pamphlets, in a quarterly periodical, and a long series of theological works. His tenets, and those of the Brethren in general, are strictly Calvinistic: original sin and predestination, the efficacy of Christ's sacrifice, the merit of His obedience, the power of His intercession, the gracious operations of the Holy Spirit in regeneration and sanctification are prominent points. Pre-Millenarian views are generally entertained by the Brethren; and they usually practise the baptism of believers without regard to previous infant baptism. Among a section household baptism has come to be practised. They partake of the Lord's Supper every Sunday, or 'first day of the week.' They utterly reject the rite of confirmation. Their most distinctive peculiarity, when contrasted with other Calvinistic churches, is their complete rejection of ecclesiastical organisation. They suppose the whole Christian body in the world to have declined from truth and duty, like Israel of old, and therefore to have been 'corporately rejected of God,' and believe that the church consists of all true believers in the Lord Jesus to whatever denomination they may belong—holding uniformly that no unbeliever or unregenerate person ought to be recognised as in the church of God. They refuse to recognise any humanly devised form of church government, or any official or salaried ministry; they insist on the privilege and responsibility of every individual to minister according to his gift and ability, in order to the edification of the whole. Practically the number of those fitted publicly to teach or minister the Word of God is very limited, and those who are not fitted for such ministry are not encouraged and sometimes restrained.

They distinguish widely between pastors, teachers and exhorters, whose ministry is to the church, and evangelists, whose ministry of the gospel is toward the world. Whilst disavowing human qualifications and ordination as generally practised, and condemning wholly as misapprehensive the distinction of 'clergy and laity,' they hold that it is right to own such evangelists, pastors, and teachers as Christ the Head of the Church has bestowed and the Holy Spirit has qualified. Such as devote themselves wholly to the work of the gospel are supported by voluntary and unsolicited contributions. In their assemblies there are frequent pauses, and liberty therefore for any member to lend in prayer or praise or to exhort or teach as he may judge to be for edification, guided by spiritually enlightened understanding of what is fitting and in harmony with what has gone before. Women are not allowed to take public part in the assembly. Persons proved to have been guilty of the sins mentioned in 1 Cor. v. 11 are excluded from the fellowship, as well as those who deny foundation truths of Christian doctrine, until evidence of repentance satisfactory to all is forthcoming. The Plymouth Brethren reject every distinctive appellation but that of Christians, although a special denomination is found necessary to designate them; no one not holding their views could remain associated with them. A schism took place among them in consequence of doctrines preached at Plymouth concerning the human nature of Christ; Darby vigorously opposing what he deemed a dangerous error, and he and his adherents utterly separating from the fellowship of those who maintained it, or refused to condemn it, and also from all who, even

though personally clear of the error, refused to endorse the extreme form of separation demanded by Darby. The Darbyite section since Darby's death has been more than once divided about various questions of doctrine and discipline.

See the works of Darby, Kelly, C. H. Mackintosh, and J. G. Bellett; and books for or against the doctrines of the Brethren by Trotter (1856), Groves (1867), Reid (1875), Miller (1879), Tenlon (1883), Neatby (1901).

PİZEŃ. See PİLSEN.

Pneumatic Despatch, the name given to a method of sending written documents, chiefly telegraphic despatches, through a comparatively narrow tube by means of compressed air and by a partial vacuum. Early in the 19th century Mr Medhurst proposed to construct a railway on this principle with carriages moving through an air-tight tunnel (see **MURDOCK**). But Mr Latimer Clark, C.E., was the first to carry out a plan for the transmission of telegrams by pneumatic power. In 1853 he got a tube laid between the central station of the International Telegraph Company and the Stock Exchange, London, through which a carrier containing despatches was propelled by a current of air produced by connecting the tube with a vacuum holder. An improvement on this was made in 1858 by Mr Varley, C.E., who introduced compressed air for the outward and retained the vacuum method for the inward traffic. This method is still in use.

The essentials of a pneumatic despatch are the exhausting and compressing pumps worked by a steam-engine or electric motor; a metal tube of copper or brass inside buildings and of lead for street tubes, where it is protected by being carried in cast-iron pipes; a small carrier of gutta-percha or other material to contain the despatches; and a suitable arrangement of valves at the stations for connecting the tube or tubes with the compressed air or vacuum mains. It has been found by experience that with heavy traffic, such as that at the telegraphic department of the London Post-office, a lead, brass, or copper pipe $1\frac{1}{2}$ or $2\frac{1}{4}$ inches in internal diameter is a convenient size. The method of working is this: At the central station end of the tube there is a double sluice valve, and when the carrier is inserted into the message chamber (the widened end of the pipe) the lower slide of the valve is drawn so as to close the mouth of the pipe, but on the rod of the slide there is a stop which actuates a lever and rack, and this opens the upper slide in front of the carrier. At the same time, by a separate arrangement, a valve is opened to admit compressed air, which forces the carrier forward. When its arrival at the other end of the tube is signalled electrically, the slide is moved so as to cut off the air from the pressure main, and then the chamber at the mouth of the pipe is ready for another carrier. From the distant end of the pipe the carrier is drawn or sucked to the central station by making a connection at that station with the vacuum main instead of the pressure main. Carriers are introduced into the tube through an opening normally covered by a sleeve, which slides along the tube to open or close the slot; this arrangement, which is used on hand-worked systems, is called a 'feed-slide.' On power-installations 'door despatch' terminals and 'funnel despatch' terminals are used, and in the latter the carrier must always be entered in an upward direction to prevent the intrusion of foreign matter with the air entering the tube. The usual form of receiving apparatus is called a flap terminal. It consists of an enlargement in the tube, which must be vertical at this point, one side of which consists of a light aluminium door hinged at its upper end to open outwards, and provided with a soft leather seating. The air is drawn through this chamber and the vacuum is sufficient to keep the door closed, but on

the descent of a carrier a curved grid within the chamber guides it so that it strikes the door, and is carried out into the wire cage which surrounds the apparatus, the door closing automatically under the control of a light spring.

At street tube-stations for sending or receiving, the double-slide switch is used. This consists of a pair of parallel sector-plates joined by two lengths of tube, A and B, each capable of accommodating a carrier in a vertical position. This framework moves radially about a vertical pivot (situate behind the service-pipe) between two plates, to which the ends of the service-pipe are attached in such a way that either A or B may be at will moved into position between the two ends of the service-pipe, without loss of air, by means of a lever. If the handle is at rest toward the right, a carrier arriving falls into the tube A, and is observed through the small window; the handle being moved toward the left, the tube A moves to an opening in the lower plate, through which the carrier will fall. If it is desired to send a carrier it is placed in tube B through a funnel-hole in upper plate, after which connection is established between B and the tube in the same way by moving the lever to the left from its position of rest. Various other types of terminals are in use according to the service required. For a distance of 1000 yards with a 2½-inch tube the time of transit is one minute when the air pressure is 10 lb. per square inch or with an equivalent effective vacuum of 6½ lb. per square inch. With the air pressure and vacuum usually employed, a speed of from 25 to 35 miles per hour is attained in tubes not exceeding a mile in length. A higher pressure is, however, sometimes used. The speed varies inversely as the square root of the length of the tube. The pneumatic service of the British post-office has been gradually increasing until the system, which in 1854 was represented in London by one 6 horse-power engine working a single tube of a few hundred yards in length, comprised in 1925 in London alone over 64 miles of tubes working between more than 75 stations, while in that year nearly all pumps had been converted to be driven by electrical power. The newspaper offices in most of our large towns have pneumatic despatches in connection with the telegraphic instrument rooms of their respective post-offices, beside which large numbers of 'house' systems exist in local and central telegraph offices. Many department stores also have pneumatic systems for sending bills and cash to the central pay desk and returning them. In Paris and some other towns on the Continent, instead of several tubes radiating from a central to outlying stations, one tube or tubes alongside each other from the central telegraph office form a continuous circular line with intermediate stations, and several carriers linked together are sent at one time. In some of these continental pneumatic despatches the pipes are of iron instead of lead, and there are other differences of detail. Berlin has an extensive installation. In the United States great progress has been made in the use of pneumatic power for post-office work. Mr B. C. Batcheller, an American engineer, invented an improved system which, from its completeness and simplicity, gives promise of very extended use in future. It consists of double tubes of wrought iron running parallel to each other. At the central station a steam-engine of 25 horse-power for every mile of tube compresses the air and forces it into one of the tubes, along which it rushes, returning by the other, a constant current being kept up. Cylinders of steel weighing about 13 lb., and having a capacity of about 800 cubic inches, are loaded with the letters, or whatever is to be sent, and, by an ingenious arrangement, introduced into the tube without

interrupting the current. They are propelled at the rate of the current, and on arrival at the terminus are delivered into an air-chamber which stops them, also without interrupting the current, which returns by the other tube. At intermediate stations another ingenious device delivers cylinders, specially fitted for each station, at the proper places. The system was first tried in Philadelphia in 1893, the tubes used being 6 inches in diameter. One of the lines, 1 mile in length, was traversed in 85 seconds. In Boston 8-inch tubes were used, and carried over 360,000 letters per day between the post-office and the railway station. New York post-office has three sets of tubes: one to the Grand Central Station (3½ miles), with 3 intermediate stations, carries 6000 lb. of letters daily at the rate of 7 minutes each way. In 1900, by sanction of the authorities, Mr Batcheller formulated a complete scheme for London. Its use for small parcels as well as letters and telegrams might do much to relieve the congested traffic in the streets.

It has been several times proposed to utilise the pneumatic tube for passenger traffic, and a piece of railway of this kind was laid down in the Crystal Palace grounds in 1865 by Mr Rummel. It consisted of a single line of rails in a tunnel 600 yards in length, along which a carriage carried passengers. Motion was given by alternate blowing and suction; but it was little more than an experiment, and was not permanent. Electricity has proved a much more useful power than air for this purpose.

Pneumatic power is capable of application in many other directions than the despatch of telegrams and papers, &c. It is extensively used in working tools of all kinds for riveting, hoisting, drilling, metal-cutting, hammering, air-lift-pumping, spray-painting, &c.; and it is in many cases superseding steam and rivalling electricity (see COMPRESSED-AIR MOTOR). In railway work it is used for actuating the brakes on the trains either as air pressure, as in the Westinghouse, or otherwise in the vacuum brake, and several British railways have now introduced pneumatic signalling, either entirely pneumatic or in combination with electricity, as electro-pneumatic methods of working their signals, which have been successfully used in many American lines. The motive power is compressed air contained in an underground pipe, the pressure of which, by means of pistons, is made to work signals at any reasonable distance. The action is quicker; fewer signalmen are required; the complicated system of rods and levers will be dispensed with; the new apparatus is not so apt to get out of order as the old, and will be much cheaper to maintain. See also AIR-ENGINE.

Pneumatic Gun. See AIR-GUN, CANNON.

Pneumatics is a name, not very much used now, for the science that discusses the properties of gaseous fluids. It is therefore a branch of Hydrodynamics (q.v.) in the modern acceptance of that term. See also ATMOSPHERE, BAROMETER, GAS, SOUND, VISCOSITY, WAVE, WIND.

Pneumatic Trough. See TROUGH (PNEUMATIC).

Pneumogastric Nerve. See NERVOUS SYSTEM, and DIGESTION.

Pneumonia, or Inflammation of the Lungs, is the name applied (with the necessary qualification) to a number of distinct pathological conditions. The catarrhal inflammation of Bronchitis (q.v.) may extend to the alveoli of the lungs, producing scattered patches of *catarrhal pneumonia*. The inflammatory changes occurring in consumption; those found in *interstitial pneumonia*, or *cirrhosis* of the lungs; in a few cases of syphilis; in wounds and injuries of the chest; in pyæmia; in the last stage of many exhausting diseases, are all types of

pneumonia. But the most important form, to which the present discussion will be restricted, is that variously called *acute*, *lobar*, or *croupous pneumonia*, and is one of the most striking and definite of familiar diseases.

The changes occurring in an affected portion of lung are described in four stages. (1) *Congestion*: the lung-tissue still contains air, though less than in health, and is gorged with blood. (2) *Red hepatization*: the lung-tissue is solid like liver (hence the name), and is much more friable than in health; it still contains much blood, but no air, as the vesicles are completely filled with firm exudation, consisting of fibrinous material, mixed with leucocytes and red blood-corpuscles. (3) *Gray hepatization*: the tissue is still more friable and of a grayish colour, containing now little blood or blood pigment; the exudation has become much softer, as the fibrinous material has been altered, and oozes in part from the cut surface as a purulent fluid. It is doubtful whether recovery can take place when this third stage has been reached. (4) *Resolution*: the fibrinous material exuded into the air spaces is re-absorbed, and the lung again becomes filled with air. When the surface of the lung is affected, Pleurisy (q.v.) is always present as well as pneumonia.

The inflammation seldom attacks the whole of both lungs at once; the right is more often affected than the left, and the lower part than the upper. A whole lobe, or a large part of it, usually suffices; sometimes more than one.

The disease generally begins suddenly with a severe rigor or shivering fit, and the temperature rises rapidly—usually to 103°–105° F. The pulse and respirations are both quickened, but the latter much more in proportion than in most other diseases, a most important indication of the nature of the case; instead of the usual ratio (about 4 pulse-beats to 1 respiration), the proportion becomes 3 or 2 to 1. All the usual signs of fever are present; but the patient's face presents a characteristic dusky flush; there is frequently severe pain in the affected part of the chest, and usually more or less cough, painful, but short, and suppressed as far as possible. In most cases after a few days the spit becomes very viscid and tenacious, and assumes a rusty tinge; this appearance is almost sufficient by itself to show the nature of the disease; but spit as well as cough may be absent altogether. The physical signs of the disease are very distinct. There is dullness on percussion over the affected area; and on auscultation marked and very characteristic changes in the breath-sounds. But if the inflammatory process happen not to reach a portion of the lung in contact with the chest-wall it may be impossible to detect anything abnormal.

It is always a serious disease; but the great majority of cases do recover. The circumstances which make it most alarming are the presence of other disease, especially of the heart or kidneys; previous habits of intemperance; occurrence in epidemic form; and advanced age, as it is much less fatal in youth and middle life than after the age of sixty. Yet sometimes even cases apparently far from hopeful ultimately do well.

In favourable cases the fever usually terminates very rapidly—*by crisis*, as it is termed; in a few hours the temperature falls five or seven degrees, and the patient's discomfort becomes correspondingly relieved. In a very large proportion of cases this takes place between the sixth and the eighth day; but it may occur earlier, or it may be delayed to the fourteenth. After this has taken place the exudation in the affected portion of lung is gradually expectorated and absorbed, and as a rule perfect recovery takes place.

In a considerable number of cases pneumonia

seems to be brought on by exposure to cold or wet. But in the majority no such cause can be traced. Only in very exceptional instances does it seem to be infectious; but epidemics on a small scale are of not infrequent occurrence, and sometimes assume large proportions. These facts, among others, have led to the classification of acute pneumonia not with local inflammations, but with specific fevers; and the inflammation in the lung has much the same relation to the disease as the ulcers in the intestines to typhoid fever, or the inflamed throat to scarlet fever. In 1882 Friedländer found an organism in the lungs in pneumonia; and later the pneumococcus, which is almost invariably present in the sputum from cases of uncomplicated pneumonia, was described by Fränkel. But the disease also occurs during other illnesses, like typhoid fever, and may then be caused by the organisms associated with the original malady. As already mentioned, pneumonia has a special tendency to develop in the course of severe epidemics of influenza, and is then apt to be of a very fatal type.

The recognised treatment of pneumonia passed through curiously varied phases during the 19th century. Free and repeated bleedings, with extensive use of mercury, in vogue during the earlier decades, were superseded about the middle of the century by equally extensive administration of alcoholic stimulants. But it was gradually discovered that many cases recover perfectly with no other treatment than careful nursing; and the usual practice in recent times has been to assign to drugs only a subordinate place. Rest in bed in the recumbent position; a plentiful supply of fluid nourishment; light poultices, or a thick layer of cotton-wool, over the affected part, are often all that is necessary in a young and healthy subject. Severe pain may be combated by mustard poultices, blistering, or ice-bags; or it may require anodynes for its relief; sleeplessness, excessive rise of temperature, troublesome cough, or aggravation of any other symptom may require special treatment. The danger most to be feared in this disease, however, is generally weakness of the heart; and to patients of feeble constitution or advanced age stimulants—digitalis, strychnine, alcohol, &c.—are usually administered, often in large and frequent doses. Inhalation of oxygen often gives great relief, especially in cases accompanied by blueness of the face and lips.

Po (anc. *Eridanus* and *Padus*), the largest river of Italy, rises on Monte Viso, one of the Cottian Alps, at an altitude of 6405 feet, close to the French frontier. It flows eastward for upwards of 20 miles, when, arriving before Saluzzo, it emerges from its rocky defiles and enters upon the plain. From Saluzzo it flows north-north-east past Turin to Chivasso; there it changes its course toward the east, in which direction it flows to its embouchure in the Adriatic. Upwards of 55 miles from its mouth, above Ferrara, it begins to form its delta, 60 miles wide from north to south. The delta is growing rapidly in area. Ravenna, a city once on the seashore, now stands 4 miles inland. The Po receives from the left the Ticino, Adda, Mincio, and other streams, and from the right the Trebbia and others. It has an entire length of 360 miles, and drains an area of nearly 28,000 sq. m. Below Piacenza its stream has from pre-Roman days been embanked—in some places with double embankments; and the bed is now high above the plain. It has always been difficult to cross, owing to its width and, still more, the great volume of its waters; hence the strategic and commercial importance of such places as Piacenza and Turin, where the easiest fords are.

Poaceæ. See GRASSES, PASTURE.

Poaching, though not strictly a legal term, has so long been appropriated in popular speech to describe a well-known offence that it is now usually adopted in legal works. It means trespassing on another's lands in pursuit of game; and it is likewise extended to the cognate offence of unlawfully fishing in another's waters.

(1) *As to Poaching Game.*—The general law as to who is entitled to game, and in what circumstances, is stated under the head **GAME-LAWS**. In England there are a Day Poaching Act and a Night Poaching Act, imposing penalties on poachers. By the Day Poaching Act, 1831, whoever unlawfully goes upon lands not his own to pursue or kill game (q.v.), rabbits, woodcocks, snipes, quails, or land-rails is liable to a penalty of £2. Any person whatever, whether interested in the lands or not, may institute the proceedings for the punishment of the poacher; and the informer is entitled to half the penalty, the other half going to the poor of the parish. When a poacher is found trespassing on lands in search of game the person entitled to the game there, or the tenant, or a gamekeeper or servant of either may demand the poacher's name and place of abode, and if it is refused may arrest such poacher, and take him before a justice of the peace; but the poacher must be taken within twelve hours before the justice, otherwise he is entitled to go at large. In such a case a penalty of £5 may be inflicted. If game be found on the poacher at the time he is caught, and it appear to have been newly caught, the party who is entitled to arrest him is entitled to seize the game also. If the poacher when convicted do not pay the penalty within the time fixed by the justices, he may be committed to the house of correction for a period not exceeding two calendar months. The party may appeal against his conviction to the Court of Quarter Sessions; but he must either remain in custody in the interval, or give security for the costs. The offence of poaching is punished more severely when five or more go out together, and in such case each is liable to a penalty of £5. Moreover, if any of these five or more persons, acting in concert, be armed with a gun, and use violence, each is liable to an additional penalty of £5. By the Night Poaching Act, 1828, which applies to the United Kingdom, it is provided that any person by night—i.e. between the first hour after sunset and the first hour before sunrise—unlawfully trespassing in search of game shall for a first offence be committed by the justices to the house of correction for a period not exceeding three months; for a second offence shall be committed for a period not exceeding six months, the convicted person being in each case liable to a further term of imprisonment on failure to give securities at the end of his sentence; and for a third offence shall be guilty of a misdemeanour, and be liable to penal servitude or two years' imprisonment. In case such night-poachers are found on the lands and in the act, the owner or occupier of the land or his servants may arrest the poachers, and take them before justices. If the night-poacher, when arrested, use firearms, sticks, or offensive weapons, he shall be guilty of a misdemeanour, and be punishable by penal servitude or two years' imprisonment. In case of three or more night-poachers being armed with guns, bludgeons, or other offensive weapons, each is guilty of a misdemeanour, and is liable to penal servitude or imprisonment for three years. The provisions of the Night Poaching Act were, by the amending Act of 1844, extended to public roads and highways, it having been found that the original act was evaded, and the risk of murder greatly increased by poachers frequenting such places.

Under the former law it was, as already men-

tioned, incompetent for any person except the owner or occupier of the lands or their servants to apprehend the poacher, and even this could be done only when the poacher was caught in the act on the lands; and hence even constables had no power to seize the poacher, though seen to be coming from such lands. But by the Poaching Prevention Act, 1862, which applies to the United Kingdom, if a constable meets a suspected poacher in any public place, whom he has reason to suspect of coming from land where he has been poaching, and of having in his possession game unlawfully got, or a gun or net, such constable may stop and search the poacher; and if game, or implements for taking game, be found on him, may seize and detain them, and summon the poacher before the justices. When before the justices, if it be proved by circumstantial evidence or otherwise that such game was procured by poaching, or that the implements were used for poaching, the poacher may be fined in a penalty of £5, besides forfeiture of the game, and guns, nets, and other implements which he may have so used. The constable may also stop and search any cut in which he suspects there may be such game or implements. The person convicted may appeal, if he chooses, to the next Quarter Sessions, or, in certain cases, to the Court of King's Bench. A conviction can be obtained only in cases of actual seizure of game or implements, but for a conviction it is not necessary that the poacher should be seen actually committing the offence. Poaching hares or rabbits by night in any warren or breeding-ground is a misdemeanour under the Larceny Consolidation Act, 1861. This act does not apply to Scotland.

As game is in the category of wild animals, in England the poacher is entitled to keep the game unless it was both started and caught on the same person's lands. But, as stated above, game may be taken from a poacher if the demand is made at the time on the land or on fresh pursuit.

The law of Scotland as to poachers does not materially differ from that of England, and the Night-poaching Acts apply to Scotland. The Scots Day Trespass Act, 1832, closely agrees with the English Act. In Scotland game is the property of the captor, and accordingly where there is no statutory forfeiture the offender is entitled to retain game found in his possession. It is not necessary under the Scots Day Trespass Act for the seizure of game in the possession of a poacher that the game should have been recently killed. On conviction of a third offence of night-poaching in Scotland before the High Court of Justiciary the offender is liable to penal servitude. In Ireland the law as to poaching is not identical with the law of England, but substantially the provisions are the same.

The law of the United Kingdom has often been described as too severe against poachers, inasmuch as most of the penalties, except in Ireland, are cumulative. But it is answered that poaching is in reality only stealing under a milder name, game being as much the fruit of the soil, dependent upon the care and protection of the owner or occupier, as apples or turnips, and that the transition from habitual poaching to stealing is not only easy, but inevitable. Present-day poaching is seldom picturesque, and is generally sordid, and too often it is associated with other forms of crime. See the article upon **GAME-LAWS**. The administration of the law by justices, many of whom preserve game, is also objected to. As regards Scotland this objection was removed by the Game Laws Amendment Act, 1877, under which all summary prosecutions for poaching must be conducted before the sheriff or his substitute.

Jefferies, *The Gamekeeper at Home* (1878) and *The Amateur Poacher* (1880); John Watson, *Poachers and Poaching* (1891); O. Jones, *Ten Years of Gamekeeping* (1909); O. Jones and M. Woodward, *A Gamekeeper's Note Book* (1910).

(2) *Poaching Fish* is the unlawfully entering on another's fishery in order to catch fish. *Salmon-poaching* will be found treated under the head of SALMON. The law of fisheries is not uniform in the United Kingdom. In England the general rule is that any one of the public may fish freely in the sea and in all navigable rivers as far as the tide flows; and where he can fish he can catch salmon as well as every other kind of fish. But there is an exception to this generality, which consists in this, that as the crown could before Magna Charta (which took away such right) legally grant a several or exclusive fishery in the sea or a tidal river to an individual, and as this was, in point of fact, often granted, it follows that it is not uncommon to find, even at the present day, an individual, generally the lord of an adjacent manor, still claiming a several fishery in these places. If he can prove that he has exercised this exclusive right as far back as one or two centuries it will be inferred that his right dates from before Magna Charta, and it will therefore be sustained. When such is the case the public have no right to fish even in a tidal river or the sea at the specified places, the sole fishery being vested in this individual owner. In streams not tidal the rule is that each riparian owner—i.e. the owner of the lands on the bank of the stream—has a right to a several or exclusive fishery up to the middle-line of the stream. If he is owner on both sides of the stream then he has the exclusive fishery in the whole of the stream, so far as his lands extend. As to ponds, whoever is owner of the soil is the owner of a several fishery therein. As to lakes, it is not clearly ascertained how the fishery is to be divided between the owners of the lands abutting thereon; but much will depend on the title to the lands and the subsequent user. As a general rule, there is no such thing as a right in the public to fish anywhere except in a tidal river or the sea, and that is subject to the exception of an individual claiming a several fishery, as before mentioned. It is often supposed that if a highway adjoins a private stream any one may fish in the stream or angle there; but this is a delusion. Nobody is entitled to use a highway for the purpose of fishing or pursuing game, the use of the highway, so far as the public are concerned, being confined to the purposes of travelling or transport. The general rule as to all several—i.e. exclusive—fisheries is that whoever poaches the fish commits an offence, for which he may be summoned before justices and fined £5, over and above the value of the fish taken; and if the fishery where he poaches is adjoining the dwelling-house of the owner of the fishery it is a still higher offence, for it is then an indictable misdemeanour. The Fish-poaching Code of England is contained in the Larceny Act, 1861. It is immaterial what kind of fish is caught by poachers, and how they are caught. But a milder punishment is awarded to the poaching *angler*, for even though he poach in a fishery adjoining the owner's dwelling-house he incurs only a penalty of £5; and where the fishery does not adjoin a dwelling-house he incurs a penalty of only £2. Whenever a fish-poacher, other than an angler, is caught in the act of poaching he may be at once apprehended, not only by the owner of the fishery, but by anybody; but this

can only be done while he is on the spot or near it, for if he escape to the highway or to other lands before being arrested he cannot then be apprehended, but can only be summoned before justices in the usual way. In this respect a privilege is given to *anglers*, for in no case can they be arrested, if angling during the daytime; they can only be summoned for the offence. The poacher, when arrested, must be taken within a reasonable time before a justice of the peace, and charged with the offence. In regard to the fish poached the rule is that whoever first catches the fish, whether legally or illegally, is entitled to keep it; so that the poacher, whatever other punishment he may incur, does not lose his fish. With regard, however, to the poaching implements, such as nets, it is provided by an express section of the Larceny Act, 1861, that the owner of the fishery or land where the poacher is caught, or his servant, may demand, and if refused may seize, the net, rod, line, hook, or other implement used for taking the fish, but no other person can seize these. Large powers to arrest are given to water-bailiffs acting under the Fresh-water Fisheries Act, 1923.

The law of Scotland differs considerably from that of England. As regards fish other than salmon the general rule is that the riparian owner is entitled to catch all the fish he can, provided he do not interfere with the superior right of some crown grantee of the salmon-fishery. A person who poaches trout or other fresh-water fish with a net, or by double-rod fishing, or cross line fishing, or set lines, &c., incurs a penalty of £5, besides forfeiture of the fish caught. And he may be arrested if he is net-fishing, but not if he is fishing in another way. Moreover a mere angler of trout, though a poacher, cannot be arrested nor yet punished by any penalty; though he is liable to an action of interdiction. In the case of all poachers of trout (except *angling poachers*, who can neither be arrested nor yet have their fish or fishing-rod taken from them by force), the owner of the fishery or any person authorised by him may seize the nets, boats, and fishing implements if the poachers are found on the spot. See the Fresh-water Fisheries (Scotland) Acts of 1845, 1860, and 1902; the last enacts a close time for trout in Scotland between 15th October and 28th February (inclusive), imposes a penalty for using explosives to kill fresh-water fish, and further modifies former acts. There is a special code, somewhat more stringent than the ordinary law, applicable to the river Tweed. The Irish law is practically the same as the English.

See *Waterson's Fishery Laws* (new ed. 1873); *Oke's Fishery Laws* (4th ed. 1924); Moore, *History and Law of Fisheries*, and *Handbook of 1923 Fisheries Act*, a-d, for Scotland, Stewart on *Rights of Fishing* (1869).

Pocahontas, daughter of an Indian chief, Powhatan, born about 1595, figures prominently in the American travels of Captain John Smith (q.v.) in connection with the part she played in the history of the early English colonists in Virginia. The expedition under Captain Bartholomew Gosnold and others had landed in Chesapeake Bay in 1607. The James River was explored, and a settlement formed, but a great drawback was the lack of food-supplies. In one of the expeditions for food, and to explore the Chickahominy, Smith was taken prisoner, brought before the chief Powhatan, and his head laid on a stone preparatory to having his brains beaten out with clubs. At this juncture Pocahontas, then a young girl, 'when no entreaty could prevail, got his head in her arms, and laid her own upon his to save him from death.' She again saved Smith's life in 1609 by informing him of a plot by her father against him. She was brought a prisoner to Jamestown by Captain Argall in

1613. She married an Englishman, John Rolfe, in 1614, is said to have embraced Christianity, and came to England with her husband in 1616. During her residence of seven months in England Smith petitioned Queen Anne on her behalf. Having embarked with her husband for Virginia, she died off Gravesend in March 1617. She left one son, and a branch of the Randolphs and several other Virginia families claim descent from her (Robertson and Brock, *Pocahontas and her Descendants*, Richm. 1887). Charles Deane, in his notes to his reprint of Smith's *True Relation* (1866), first started doubts as to Smith's veracity in connection with the Pocahontas incident, and this scepticism has been shared by other writers.

Pochard (*Fuligula*), a genus of diving ducks which are marine during the greater part of the year. One of their distinctive structural features is a membranous lobe on the hind toe. The Common Pochard (*F. ferina*) is a winter visitor to Britain, and sometimes breeds by the shores of inland meres. The Red-crested Pochard (*F. rufula*) is a rare wanderer to Britain; so is the Ferruginous (*F. ayra*), while the Tufted (*F. cristata*) and the Scaup (*F. marila*) are much commoner, and sometimes breed in suitable inland resorts. Nearly allied to *F. ferina* is an American species (*F. americana*), and the Canvas-back Duck (q.v.) also belongs to this genus.

Pocklington, an urban district in the East Riding of Yorkshire, 13 miles ESE. of York. It has a good Early English church (restored 1850) and a grammar-school (1514; reconstituted 1875), where W. Wilberforce was educated. Pop. 2600.

Pocock, EDWARD, a learned orientalist, was born in 1604, and educated at Corpus Christi College, Oxford, of which he was elected fellow in 1628. He early devoted himself to oriental studies, and sailed for Aleppo in 1630 as chaplain to the English factory, but returned in 1636 to fill Laud's newly-founded Arabic chair at Oxford, and received in 1643 the college living of Childrey. His estimable character and great learning raised up for him during the troubles friends like Selden and Owen. He was appointed to the chair of Hebrew in 1648, but his inability to take the engagement of 1649 deprived him of the salary down to the Restoration. He survived till 1691. Pocock's learning was really remarkable, even apart from all allowances for his time. His *Porta Mosii* (1655)—extracts from Maimonides' Arabic commentary on the Mishna; the *Annals of Eutychius* (1656), in Arabic and Latin; and an edition of the Arabic history of Barhebraeus (1663), were followed by Commentaries on Micah (1677), Malachi (1677), Hosea (1685), and Joel (1691).

Pococke, RICHARD, 'the Traveller,' was born at Southampton in 1704, and educated there and at Corpus Christi College, Oxford. Precentor successively of Lismore and Waterford, then Archdeacon of Dublin (1745), in 1756 he was consecrated Bishop of Ossory, and had just been translated to Meath, when, on 15th September 1765, while on a visitation, he died very suddenly at Charleville, near Tullamore. His travels, which took up nearly nine years of his life, and in which he must have ridden some 52,000 miles, are described in two folios dealing with his four years' wanderings in Syria, Egypt, and Mesopotamia (1743-45), in a volume on his tours in Scotland (Scottish History Soc., 1887), in two on his tours through England (Camden Soc., 1888-89) and in one on Ireland (edited by J. T. Stokes, 1891)—books that are as dull as they are valuable. Pococke was, moreover, the pioneer of Alpine travel, for in 1741 he led a dozen Englishmen, all strongly armed, to the Vale of Chamouni, whose grateful inhabitants carved his name and

the date on a huge granite boulder close to the Mer de Glace.

Pod. See FRUIT.

Podagra. See GOUT.

Podargus, a genus of birds nearly allied to the true Goatsuckers. They are at home in New Guinea and Australia, are arboreal and nocturnal in their habits, and feed on large insects, which are mostly caught about the trees. Some of them are so sleepy during the day that Gould says they may be occasionally caught by the hand, or one may be shot without waking its neighbour. They make rough nests in the eucalyptus or casuarina trees, lay two eggs of spotless white, and the work of hatching is shared by both sexes. A podargus is usually larger than a goatsucker, and has a wider gape; the oil-gland seems to be absent, and the rump bears two remarkable tufts of small brittle feathers, known as 'powder-down patches.' One of the Australian species, *P. cavirostris*, disturbs the night by a hoarse cry resembling the syllables *More Pork or Mopok*, by which names it is therefore known in New South Wales.

Podestà (Lat. *potestas*, 'power'), an Italian municipal magistrate, sometimes with supreme administrative and military power, sometimes merely judicial.

Podgoritz (Serb. *Podgorica*), a fortified town of Montenegro, 16 miles E. of Cetinje, ceded by Turkey in 1879; pop. 10,000.

Podiebrad. GEORGE BOCKOZ of Podiebrad, Bohemian king, was born of a noble family at Podiebrad on 6th April 1420, and became an adherent of the moderate party of the Hussites (see HUSS). When the Catholic barons (1438) carried the election of Albert II. (V. of Austria), Podiebrad allied himself with the Utraquists in Tabor, who offered the sovereignty of Bohemia to Casimir, king of Poland. After forcing Albert to raise the siege of Tabor and retire to Prague, Podiebrad was recognised as the leader of the Utraquists; then he seized upon Prague (1448), and got himself made governor or regent of Bohemia, from 1452 to 1457, for the young king Ladislaus. On the death of Ladislaus, Podiebrad was chosen his successor, and was crowned early in 1458. By skilful management and wise policy he succeeded in allaying the bitterness of religious zeal, but only for a while. In 1462 he decided to uphold the terms of the *compactata* of Prague (1433); this angered the pope, Pius II., and he was only prevented from excommunicating Podiebrad through the special intervention of the emperor. The next pope, however, Paul II., did in 1466 promulgate against him the ban of excommunication. Matthias Corvinus of Hungary was the only prince who took the field to enforce it; but him Podiebrad surrounded at Wilanow (1469) and forced into a truce. Nevertheless Matthias was crowned king by the Catholic barons at Olmutz immediately afterwards. Podiebrad died on 22d March 1471, having already made arrangements whereby a Polish prince should succeed him.

Podkarpatská Rus, or CARPATHIAN RUTHENIA, a district on the southern slopes of the Carpathians with part of the Theiss valley, detached from north-eastern Hungary in 1920 to form the autonomous easternmost province of Czechoslovakia. Area, 4886 sq. m.; pop. (1921) 606,568, of whom more than half were Ruthenians, one-sixth Magyars, and only 20,000 Czechs and Slovaks. The capital is Užhorod (Ungvár); pop. 20,000.

Podocarpus, in respect of diversity of foliage and geographical distribution the most interesting genus of Taxaceæ. It is found in southern Asia, Formosa, Japan, Australia and Tasmania, New

Zealand, New Caledonia, Fiji, New Guinea, Madagascar, South Africa, East Africa, West Africa, Brazil, Bolivia and Argentina, Peru to Costa Rica, Guatemala, West Indies. A few species pass over from one of these regions to another, but, as a rule, each harbours a special section of the genus. In Tanganyika and on Mount Kenya they form nearly homogeneous forests; elsewhere an element in mixed forests.

Podolia, or KAMENETZ, a government (abolished 1925) of Ukraine, north of Bessarabia, and bordering on the former Austrian frontier. Area, 16,224 sq. m.; population, 3,478,000, the majority of whom are Russians. The surface is a tableland, strewn with hills; nearly three-fourths is either arable or available for pasturage.

Podophyllum, a genus of plants of the family Berberidaceae, comprising several species found in north temperate countries. The genus *Podophyllum* has three sepals, six to nine petals, twelve to eighteen stamens, a broad round stigma seated almost on the top of the ovary, and a many-seeded berry. *P. peltatum* is a perennial plant, common in North America, growing in moist woods and on the shady banks of streams, and is known as *May-apple*, because it flowers and ripens its fruit very early in summer; also as *Hog-apple* and *Wild Lemon*. The rhizome sends up each year a shoot bearing two peltate leaves, about five inches across, and a solitary drooping white

Leaf, Flower, and Fruit of *Podophyllum peltatum*.

flower. The fruit may be eaten, but is not agreeable. All the other parts are actively cathartic. Another species (*P. Emodi*) is a native of the Himalayas, and has the same medicinal properties (recognised in the British Pharmacopoeia since 1914), but in 1889 was shown to yield three times as much of the valuable resin as the American plant.

PODOPHYLLIN is the resin obtained by means of rectified spirit from the rhizome. In the British Pharmacopoeia the rhizome is official, but is only used to prepare the resin (*Podophylli Resina*). The latter is an active purgative, and seems to have the power of relieving the liver by exciting copious bilious discharges. The dose is 16 to 66 milligrams; its action is slow, generally taking about eight hours. It is apt to gripe, and hence is usually given along with carminatives, or in small doses combined with other purgatives.

Podostemaceae, a family of dicotyledons growing in rapids and waterfalls of tropical rivers. The vegetative organs are very varied, and in great part take the form of a thallus, resembling a seaweed or lichen rather than a flowering plant. This thallus may be shoot or root in nature. The dorsiventrality is remarkable.

Podura. See SPRING-TAILS.

Poe, EDGAR ALLAN, poet, critic, and romancer,

was born 19th January 1809 at Boston, where his parents spent three years as actors. His mother, Elizabeth Arnold, was a young English actress; his father, David Poe, a player of loose habits, the runaway son of a revolutionary veteran at Baltimore. Orphaned at Richmond in his third year, Edgar was adopted by John Allan, a wealthy and childless tobacco-exporter, who hailed from Ayrshire, Scotland. In 1815 the family went to England, and the boy was sent to school at Stoke Newington. From their return in 1820 till 1825 he attended a classical school at Richmond. The year 1826 was spent at the University of Virginia. Incensed by his gambling debts (over 2000 dollars, it is said), his patron cut short his academic career, whereupon Poe ran away to Boston. Here he published *Tamerlane and other Poems*, by a Bostonian, 1827, a pamphlet of 40 pages (reprinted in London, 1884). Under the new pressure of poverty he enlisted, 26th May 1827, as Edgar A. Perry, giving his age as twenty-two. He served, apparently without fault, in the First Artillery at Forts Independence, Moultrie, and Monroe, and rose to be sergeant major 1st January 1829. He now effected a reconciliation with Mr Allan, who procured his discharge, 15th April, and after a year's delay his admission to West Point. Meantime his second volume, *Al Araby, Tamerlane, and Minor Poems*, appeared with his name at Baltimore, 1829, 71 pages. He entered the Military Academy, 1st July 1830, recording his age as nineteen. Discipline and constraint did not suit him, and by deliberate neglect of duty he caused his dismissal, 7th March 1831. Having quarrelled violently once more with his foster-father (who had married again), he was thrown finally on his own resources, which were probably confined to cadet subscriptions to his *Poems*. The volume appeared as a 'second edition' (it was really a third) in New York, 1831, 124 pages, and contained *Trafalgar*, his earliest poem of value, and *To Helen*, in a first draft.

Of his life in Baltimore during the next two years few records remain. Nearly the first earnings of his pen consisted in the \$100 prize won by *A M.S. found in a Bottle*, in October 1833. He declined an invitation to dinner 'for reasons of the most humiliating nature—my personal appearance.' John P. Kennedy befriended him, and even, by the testimony of both, saved him from starvation. From this time he lived with his aunt, Mrs Clemm, and wrote for the *Saturday Visitor*. His connection with the *Southern Literary Messenger* began with its publication of his tale *Berenice* in March 1835; a few months later he went to Richmond as its assistant-editor. The Clemms soon joined him, and on May 16, 1836, he married his cousin Virginia, who was then not fourteen, though a friend swore that she was 'of the full age of twenty-one.' For more than a year he worked hard and usefully on the *Messenger*, which printed many of his tales, criticisms, and poems, gaining great repute thereby. But Poe was 'irregular, eccentric, and querulous,' and these qualities, with the aid of stimulants, cost him more than one place. He left Richmond in 1837, and after a year or less in New York, of which the chief apparent fruit was *The Narrative of Arthur Gordon Pym* (1838: 198 pages), in the summer of 1838 established himself (if he could be said at any time to be established) in Philadelphia.

Here he prepared *The Conchologist's First Book* (1839), the matter of which was taken from Cuvier, Wyatt, and Brown; procured at length the publication, without profit to himself, of *Tales of the Grotesque and Arabesque* (2 vols. 1840); was connected with Burton's *Gentleman's Magazine* (1839); projected in 1840 the *Penn Magazine*, which

came to nothing, and in 1843 *The Stylus*, which he never gave up the hope of starting; and for a year (1842-43) edited *Graham's Magazine*, then in the forefront of American literature. Long periods of sobriety and patient though ill-requited labour would be interspersed with fits of reckless indulgence and months of desperate poverty. His wife's dangerous illness, caused by the rupture of a blood-vessel while singing, numbed him, and weakened his always slight power of self-direction. A second prize of \$100, won in 1843 by his wonderful story *The Gold Bug*, again saved the little household from starvation or near it.

In April 1844 he removed to New York, and from October to March following assisted Willis on *The Evening Mirror*. Here *The Raven* appeared, January 29, 1845, and won immediate fame. For a few months he was associated with C. F. Briggs in the *Broadway Journal*, which became notorious by his assaults on Longfellow as a plagiarist. In this year he published a volume of *Tales, and The Raven and other Poems*. In the spring of 1846 he occupied the famous cottage at Fordham. Here, January 30, 1847, in deepest poverty, Virginia Poe died, an attractive and pathetic figure, retaining her fragile and childish beauty to the last; she was but twenty-four. Her mother was more than a mother to the poet, and his home life drew out what was best in his nature, and afforded such measure as he attained of happiness.

Except for *The Bells*, *The Domain of Arnheim*, the wild psycho-astronomic 'prose poem' *Eureka* (1848), and a few minor pieces, the brief remainder of his life might to advantage be forgotten. Unable to stand alone, he sought vainly, and with an eagerness that approached insanity, to replace what he had lost. He was no libertine; his writings and his life were chaste; with women he was deferential, tender, chivalrous. He idealised them on the smallest provocation, and in these latter years he could not keep his imaginings in their proper place. Mrs Whitman was not the only object of his homage, and his frantic appeals to her, strangely intermingled with his room potations and an attempt at suicide (November 1848), were but the most striking and pitiable indications of a mind unhinged. Two months later he was deep in pen-work, and wrote to his 'Annie' that he was 'so, so happy,' with 'how great a burden taken off' his heart. In the spring Mrs Clemm wrote to the same 'Annie,' 'I thought he would die several times. I wish we were both in our graves.'

Starting southward, June 30, he had an attack of debrum tremens in Philadelphia. Recovering, his ticket was furnished by friends who considered it unsafe to trust him with money. He spent over two months in Richmond, lecturing there and at Norfolk, and receiving many attentions. A physician warned him that 'another such indulgence would probably prove fatal.' He became engaged to a lady of means, and about September 30 left Richmond, intending to wind up his affairs in the north and return for his wedding in October. On the 3d of October he was found in a wretched condition at a voting-place in Baltimore and removed to a hospital, where, after expressing the most poignant remorse, he died, October 7, 1849.

Poe's character has been the subject of much heated controversy. It was malignantly vilified by R. W. Griswold, whom he had chosen as his biographer and literary executor, in a *Memoir* prefixed to vol. iii. of his collected works (1850), but since suppressed. After all allowance made for the infirmities of a sensitive spirit, bearing an inherited taint and bowed down by 'numercifal disaster,' the fact remains that he was the main author of his misfortunes. His splendid intellect

seemed to lack certain qualities bestowed on common men. The 'Imp of the Perverse' was always at his heels. At forty he was no better nor worse than at seventeen, except that his constitution was undermined by excesses. He wrote to Lowell in 1844, 'My life has been *whim*, impulse, passion, a longing for solitude, a scorn of all things present.' The kindly Briggs, after months of daily intimacy, called him 'characterless' and 'utterly deficient of high motive.' He was more diligent in defeating his own ends than in seeking them, in making enemies than in keeping friends. Except Willis, he quarrelled with all his employers and associates. The direst necessity could teach him prudence only by fits and starts. He was not responsible, reliable, respectable—at least, never for two years together. He worshipped Beauty, caring little for her elder sister Truth; from youth he falsified the facts and dates of his own life, so that his history became a puzzle to be solved by slow and painful labours. Profoundly immoral, morbid and hectic in his moods, he could bear neither prosperity nor adversity; 'any motion would upset him, and his worst falls were after successes, or with success just in sight.' A mixture of the seraph and the tramp, he oscillated between the skies and the gutter, gravitating gradually downwards, because he had no god but self. Ambition, aspiration, self-respect, and the strongest love of which he was capable—his only real love, for his devoted child-wife—could not keep him from the brandy and opium which he knew to be his poisons.

As to his genius there is little room for question. Weird, wild, fantastic, almost ghoulish (judged by its results), finding its joy in gloom and its chief inspiration in memories or imaginations of dead women, dwelling by choice and habit on themes of ruin and desolation, on the awful, the horrible, even the foul, it was yet most genuine and notable; if not of the highest order, among the most picturesque and striking gifts ever vouchsafed to man. His ratiocinative powers were marvellously displayed in some of his tales of Parisian murders, which were highly praised and widely circulated in France. At home during his lifetime his amazing tales were strangely neglected, and he was known chiefly as a critic. In this capacity he perhaps deserved less praise, and certainly less blame, than has befallen him. Occasionally misled by hatred or friendship, he was usually honest, independent, and fearless—even reckless. But his proper work was poetry and imaginative prose. His parade of scholarship rested on the slightest foundation. Of humour he had no particle, and some of his tales are poor stuff: such sold more readily than his best. His verses are often strained, artificial, full of mannerisms; 'everything is subordinate to sound.' In these, and in the more personal of his tales, wherein great wit and madness mingle, he was 'the poet of a single mood.' He will be long remembered for a few poems and many masterpieces of brief, powerful, and most peculiar fiction. In his own walk he stands unsurpassed if not alone, with a halo of mystery, gloom, and terror about him.

Apart from earlier sketches, and Mrs Whitman's *Poe and his Critics* (1860), his life has been written by J. H. Ingram (1880), R. H. Stoddart (1875), E. J. Didier (1877), W. F. Gill (1877), Stedman (1881), G. E. Woodberry (1885, 1909). There are French studies of Poe by Baudelaire (1856), Lauvrière (1904, 1911), and Maclair (1925). Poe's *Works* were edited by Stedman and Woodberry (10 vols. 1914), J. A. Harrison (17 vols. 1902-3), J. H. Whitty (1917); the *Poems* by K. Campbell (1917); his *Letters* to his foster-father, by Mrs Starnard (1925).

POERIO, CARLO, Italian patriot, was born on the 10th of December 1803, son of a Neapolitan lawyer who had suffered imprisonment and exile in the cause of liberty. He accompanied his

father into exile, but on his return became an advocate at Naples. He was repeatedly imprisoned for his services to the liberal cause; and in 1848 he organised the famous demonstration of the 27th January, which was destined to produce the constitution of the 10th February. Under it he was successively nominated director of Police and minister of Public Instruction; but he soon resigned, and was appointed deputy for Naples to the parliament. On the 19th July 1849 he was arrested, charged with being a member of a secret society, 'the Italian Unity,' and condemned to irons. With fifteen others he was confined in one small chamber in the island-prison of Nisida. Diplomatic protests from various governments—Mr Gladstone's was declared by Garibaldi to have sounded the first trumpet-call of Italian liberty—and eloquent denunciations of the royal tyranny moved Ferdinand II. at last in 1858 to ship sixty-six prisoners to America. They persuaded the captain to land them at Cork, and Poerio returned by London to Turin. There he became a member of the parliament, and in 1861 its vice-president. He died at Florence, 28th April 1867.—The elder brother ALESSANDRO (1802-48), who fell in battle for the liberation of Venice, shared his father's exile, studied in Germany, settled in Florence, and devoted his life mainly to poetry and patriotism. His poems, which contain some of the most stirring Italian songs of freedom, have been repeatedly published.

Poet Laureate. See LAUREATE.

Poetry is that one of the fine arts which employs rhythmical language as the medium of its expression. The present form of the word is due to the old French noun *poeterie*, but both are derived from the Greek *ποιεῖν*, 'to make.' A poet was *ποιητής*, 'a maker or composer,' and poetry *ποίησις*, 'the act of making or forming.' A poem was *ποίημα*, 'a thing made and finished.' Into all these expressions there entered the sense of artistic fashioning, and poetry from the first was felt to be, like sculpture, painting, or music, the work of a creative craftsman. As we cannot conceive of sculpture without something carved or modelled, or of painting without something painted, so poetry cannot, in the first instance, be conceived without the coincident idea of language rhythmically arranged. If this idea be absent the term must be used allusively or figuratively, as its counterparts often and legitimately are in the cases of those other arts. But to the primitive conception of poetry rhythm is absolutely necessary. In other words, it is only by a license, and in a sense which is unscientific, that we can speak of anything which is not composed in verse as poetry. To this rule, however, there are some conventional exceptions which will presently be mentioned.

Verse, therefore, is the essential vehicle of poetry, and on the varieties of versification the external form of any given poetical product depends. That species of rhythm on which verse is founded is the law of regularly recurring succession of articulate sounds. Verse was defined by Edwin Guest as 'a succession of articulate sounds regulated by a rhythm so definite that we can readily foresee the results which follow from its application.' The definiteness, repetition, and formal character of verse-rhythm distinguish it from that laxer and more undulating rhythm which gives charm to fine prose. The difference is one not of amount but of kind. All good verse must be severely regulated, and must obey the laws of its own prosody. The rhythm of prose, on the contrary, must, in order to be good of its species,

be unrecurrent. No greater fault can be committed in prose than the intentional or even accidental introduction of passages which can be read as verse—that is, as recurrent rhythm. Poetry, therefore, in the English sense of the term, is, in its external form, an arrangement of syllables into verses or staves, distinguished by the rhythmical accidents of quantity and accent, and effected by the law of succession.

This definition of the external form of poetry, however, is not sufficient, and to complete it is admittedly so extremely difficult as almost to defy expression. In defining the term *poetry*, nevertheless, as an English word, the lexicographers have probably been too much rather than too little affected by the necessity of including a spiritual meaning. Hardly any one has attempted to say what poetry is without mingling the figurative with the exact sense, or at least without making the definition apply to none but good and original poetry. In speaking of sculpture and painting we do not necessarily exclude all experiments in those arts which are not successful; but poetry, in English, has come to mean something which excludes unsuccessful effort in rhythmical expression. Hence a certain confusion between the external and the internal, between a craft and an ecstasy. It would be well, perhaps, to bring the term back to its more exact meaning, but it is too late to hope to do this. Poetry must continue to mean not merely language arranged in rhythmical sequence, but verse which is also inspired by imagination, and which attains a measure of perfection in that degree at which it aims. The degree may be a low one, but if the aim is fulfilled, and the rhythmical laws are followed, the work produced must not be refused the title of poetry. The word, indeed, is capable of much expansion. Any man who has written what the world accepts as a *poëma*, a finished composition in verse, is allowed the name of 'poet,' and his other rhythmical experiments, even though many of them are unsuccessful, are broadly defined as 'poetry.' The presence of high imagination, and of a brilliant propriety of language, are presupposed in all that is called poetry, but the word must be extended to much that is not very lofty nor very skilful if we are not to slip into pedantry in its use. Wordsworth at one time was of opinion that the only strict antithesis to Prose was Metre; but it is simpler, as well as more exact, to understand by poetry metrical composition, not troubling ourselves more than is absolutely necessary in its definition about the quality of high imagination. This latter is essential indeed to the best poetry, but not to all poetry in the colloquial use of that term.

In some languages, and particularly in French, *rime* or *rhyme* is an essential part of the form of poetry. In other languages, as in ancient Greek and Latin, *rime* does not exist. In English poetry final *rime*, though not essential, is extremely common, and is the necessary ornament of the main classes of lyrical composition. *Rime* is a correspondence of sound between syllables which occur at regular intervals, and in final *rime* that recurrence always takes place at the end of a verse. It may be single, double, or even triple. Propriety and vigour in *riming* are so important a portion of the art of poetry that *rime* cannot be overlooked in the briefest survey. Where *rime* is not rejected altogether, as in blank verse (and in some strophic measures of doubtful value), it forms a main ornament of English verse-composition, and some of the most beautiful effects which poetry produces are due to the skilful arrangement of these recurrent sounds. It is only a poet of great resource and infinite accomplish-

ment who can safely dispense with this fortunate regulation of rime. To one who knows his business it offers no real restraint, but rather a support and an encouragement. As Dryden has excellently said, 'That which most regulates the fancy and gives the judgment its busiest employment is like to bring forth the richest and clearest thoughts.'

It is a popular error that the necessity of finding a rime checks the inspiration of a poet, and that he would be more fortunate if he could contrive to do without it. The universal testimony of the poets themselves does not support this notion. The best writers of verse have been unanimous in declaring that the more distinct and spontaneous are the visions which present themselves to the brain for verse-expression the more rapidly and inevitably do the rimes occur in logical sequence, the proper word fitting into its proper place with as little conscious brain-effort as the proper tone or the proper form does in the work of the painter or the sculptor. If this be so, and it seems impossible to doubt it, the difficulty which the unskilful versifier finds in riming is but another safeguard to protect us from incompetence. For those readers who declare that rime gives them no enjoyment, and is only an interruption of the sense, we can but pray that ears may be added to them.

The recognised species of poetical composition are numerous, and are exceedingly difficult to distinguish from one another, because two or more of them may frequently be found existing side by side in the same specimen. Three principal divisions are, however, supposed to include all the minor classes of poetry under general headings. These are lyrical, epical, and dramatic poetry. In the original sense all poetry was Lyrical—that is to say, was composed to be sung to a musical accompaniment, and could not be conceived except in relation to music. But at a very early period this work of song was divided into two parts, that which was regulated by the air, and that which was expressed in recitative. In the former manner were sung all the poems which were inspired by the passions, which reflected moods individual to the poet, or which were devoted to religious aspiration. In the second manner were chanted matters of narration, statements of fact, didactic, hortatory, and philosophical disquisition. The poems on an air remained lyrical poetry proper, and continued to be more or less fitted to be sung to a musical accompaniment. The poems in recitative became what is vaguely known as Epic poetry, with its attendant classes, the Satire, the Epistle, the Tale, and the Fable. From all these the musical accompaniment soon fell away. In some eastern countries, however, narrative poetry is still, when publicly recited, accompanied by a monotonous music on a stringed instrument.

Dramatic poetry has retained, in its principal branches of Tragedy and Comedy, still less of the singing quality than epical poetry. In many cases drama has thrown off the restraints of versification altogether, and is now included in the general category of poetry partly because of its traditional form, and partly because its imaginative character still links it to lyrical and epical work. The origin of drama, however, was wholly lyrical. It was out of the dithyrambic song in honour of Dionysus that tragedy sprang. The litany was chanted by a chorus that danced as it sang, and in the process of time a single personage began to break away from the chorus at intervals, and either to express aspirations of his own, or to narrate stories of the god, or to incite the chorus to fresh exertions. Comedy had a similar beginning, and by degrees not one but two and then many actors confronted the chorus and drew it into conversation. The

development of this new form of poetry was very rapid; it gained variety and a recognised code of forms within a very short time, and we now possess in the tragedies of Æschylus a body of ancient dramatic poetry still capable, as recent experiment has shown, of satisfying the demands of a modern playgoer. Here the purely lyric element, in spite of the prominence of the chorus, is already minimised in favour of the development of personal action and character, so that the subsequent transition to the form of the most modern prose tragedy is really very unessential. All the principles of dramatic poetry may be comprised in an essay on the *Agamemnon*.

Into these three elements, then, the Song, the Statement, and the Drama, all poetry that is not of a primitive nature is capable of being resolved. That which was primitive—and of this we have to conjecture more than we can prove—was probably Song alone. But, while we divide poetry into these three elements, it is not possible to make the same easy division of poetical literature. Here are found, indeed, the three great classes, but, as has been already said, they are constantly detected existing side by side in one and the same composition. The more elaborate the species of poetry the more likely are we to find upon analysis that the classes are confounded in it. In the Song we still preserve the simplest form of poem. This is a short piece in regular recurrent rhythm, expressing with the utmost conciseness a single enthusiastic and intense personal emotion, which it pours forth without deviation at a breath. When the spontaneous outburst is over the song naturally closes.

No other species of poetry is so simple as this. The Ode, which is often regarded not merely as a lofty form of lyric, but as the typical form *par excellence*, introduces a complexity. Too long and elaborate to be sung spontaneously, it verges upon drama in calling to its aid a chorus and an anti-chorus of singers; upon epic by its excursions into narrative and didactic reflection. The ode, in which we include its funeral form the Elegy, remains, however, truly lyrical in its necessary dependence upon melody. Not a line of it but presupposes a musical interpretation. The traditional fixed forms suggest the accompaniment of music to a far less degree. The Sonnet, for instance, with its dignified arrangement of full lines, admitting very slight modification of form, is singularly ill-fitted to be sung. It offers no musical variety, whereas its very beauties, and in particular those subtle harmonies which are secured by a proper attention to the structure of its quatrains and tercets, would not merely gain nothing, but would lose much by being set to music. Yet we can imagine even the sonnet chanted to some simple conventional melody, unobtrusive enough not to conceal its intellectual beauties nor that vein of reflective and pensive narration which links it to the epical order; and we must continue to regard the sonnet as essentially lyrical, notwithstanding its complexity and monotony. Not less than the song, the sonnet requires to consist of the spontaneous expression of a single intense emotion. What is true of the sonnet is true of the other traditional forms, some of which, as, for instance, the Rondeau, approach the song more closely, while others, as, for example, the grandiose Chant Royal, take their place on the further side of the sonnet, between the ode and the latter.

If in the divisions of lyrical poetry we find the other two classes occasionally present, the counterpart is still more true when we turn to a similar examination of epic and dramatic poetry. In the first case we possess an exquisite form, less successfully cultivated in England than in Italy, the Terza Rima, in which the lyrical and the epic forms

co-exist to an almost equal degree. Here it is impossible to say whether the art of narrative or the art of song predominates. Even in the pure epic neither the lyrical nor the dramatic element is omitted. Whenever a burst of enthusiasm or passion seizes the narrator he passes without transition into lyric; whenever from describing his personages he proceeds to a record of their conversation, he suddenly transforms his epic into drama. Indeed, the rank of the various sections of the epic order of poetry may almost be determined by the opportunity they give for an admixture of the others. The Epistle is one of the least lyrical sections of all poetry; it may, however, contain an element of the dramatic. Satire, when it comprises no admixture of narrative, is apt to fall very low in the poetic scale. If its passion be enthusiastic and genuine it may attain to a certain lyrical afflatus; but there is little of the instinct of song in mere rage and disdain. Pure satire is commonly sustained solely by its executive ability, and is one of those species of literature which prove the necessity of giving to poetry a definition depending in the first instance not on its truth or beauty as 'a criticism of life,' but on its rhythmical structure.

Drama, as existing in modern Europe, has lost much of the external appearance of poetry. The distinction which admits a comedy in prose within the order of poetical literature and yet excludes a novel seems an arbitrary one. But it can be accounted for on traditional grounds. The novel has always been, from the days of the later Greeks, written in prose, and properly so, for it is independent of regulated form. Comedy, on the other hand, has but very lately, and still not completely, escaped from the bonds of verse. Rhythmical form is still largely used for tragedy, although the tendency in each of the great sections of drama is to dispense with a restraint which adds to the reader's pleasure, but in a much less degree to the spectator's. In other divisions of dramatic literature verse and even rhyme are still essential. In Opera, which is a combination of song with a conventional species of drama, both are necessary; and Pastoral imperatively demands for its graceful convention the ornament of metre. Dialogue, a dramatic form, may be combined even with an epic species as a medium for giving information or exhortation. Hastily looked at, however, drama appears in its modern aspects to be divorced more and more completely from the sister branches of poetry. It is therefore important to insist on the fact that the great poetical principle of unity in variety rules here as it does in those compositions which seem more completely under its sway. Without a lyrical element holding the parts of a drama together, balancing them, and supplying them with the necessary fire and harmony, the humblest play cannot maintain its existence. It is this more or less conceded dependence upon fixed laws of form which must always distinguish dramatic literature from the varieties of prose fiction. As long as it obeys these laws it holds its place in the order of poetry, although it may have abandoned its rhythmical shape. If it throws off these fortunate restraints it either perishes altogether or it becomes a mere variety of the prose novel.

In the incessant discussion which takes place as to the nature of poetry, the real aspect of the question is too frequently obscured by a confusion between Poetry, as a craft practised by artists, and the Poetical, as a metaphysical conception. The latter, which has been analysed with extraordinary minuteness by the Germans, and in particular by Goethe and by Hegel, is not necessarily combined with any of the external forms of poetical literature. This distinction, admirably laid down by

Diotima in the *Symposium* of Plato, has been generally forgotten by those who have endeavoured to sentimentalise the art and to confine our ideas of it by such vague and futile definitions as the well-known formula 'Poetry is impassioned truth.' It seems almost waste of words to point out that while the best poetry must be impassioned and must be true, in accordance with Aristotle's dictum that the superiority of poetry consists 'in its possessing a higher truth and a higher seriousness,' yet that no definition which confines itself to moral or sentimental attributes can be adequate to distinguish an art which consists of the making of a certain definite thing in a certain definite form.

In short, and in spite of the extreme unwillingness of the metaphysician to acknowledge it, we must insist that the idea of poetry cannot be divorced from the incident of 'making,' whether we call it with Wordsworth 'impassioned expression' or employ the broader and simpler word 'execution.' Until the passion and the truth are fused into actual speech, and until that speech takes a rhythmical form, those elements may be as 'poetical' as you please, but they do not form poetry. None of the wild words of Ruskin deserve an immortality of repudiation more thoroughly than the following phrase, which is always on the lips of those who write laxly and nebulously about the poetic art. 'No weight nor mass nor beauty of execution can outweigh one grain or fragment of thought,' says Ruskin. If this were true, half of the noblest poetry in the world would cease to possess any value. Thought may and often does accompany the expression of the poetic art, but it is not essential to it in the sense in which Ruskin uses the word, as an original act of the intellectual faculty. The few poets, indeed, who have aimed at producing 'chains of valuable thoughts' have rarely succeeded in doing more than giving tenuous expression to thought reflected from other and more ratiocinative minds. Even when a poet, such as Coleridge, has been eminently deductive and argumentative in his prose, he has generally been sensuous and simple in his verse. In the peculiar sense in which Ruskin uses the word 'execution,' as directly distinguished from 'thought,' the work of the great poets has seldom possessed the latter quality in any notable degree.

It is desirable to define what is meant by 'execution,' for on this depends our whole conception of the practice of poetry as an art. It is not confined to an observance of the technical laws of this form of composition, to a correct and beautiful use of rhythm, of stanzaic form, of rhyme, and of that 'variety in unity' in which the charm of verse consists. All this is part of poetical execution, and an extremely important part. In most cases it may be said to be an indispensable part. But it is not all. Execution in poetry, as in the other fine arts, is the mechanical performance by which the effect desired is produced in the most perfect and most characteristic manner, so as in the happiest combination to illustrate the nature of the art itself and the individuality of the artist. As the medium in which the poet works is language, execution in his case is the arrangement of the best words in the best order, the best order being, in all but a few anomalous cases, a rhythmical one. The technical laws of verse, however, deal only with 'the best order.' There remain, as a part of execution, 'the best words.' This section of the definition covers all the intellectual property, the moral passion, the verbal felicity, the myriad charms and graces, of which 'the best order' is but the vehicle. It is part of a poet's technical work, part of his business as a 'maker,' to produce this manifold perfection of regulated language, and all these beauties of expression

and feeling cannot be rudely divided from that 'execution' of which they are an inherent feature. The bad poet may have the intellect of Locke or of Spinoza; he will learn by the total neglect of his verses that in poetry no weight nor mass of thought can outweigh one grain of executive skill.

It would, nevertheless, be a grave error to insist so emphatically on the importance of the outward form of poetry as to encourage neglect of its inward character. In a definition of poetry it has been deemed needful to dwell here on the fact that it is primarily an art and subjected to definite laws. But, as Jonbert has said, 'the lyre is a winged instrument, and the closest attention to its constructive mechanism will not give it the power of flight if inspiration be lacking. The vivid pleasure produced by the best poetry is due in large measure to the merits of its execution—its music, the splendour of its images, the harmony and felicity of its arrangement of language. But there is something beyond and above this 'complex feeling of delight;' there is a spiritual emotion which is the spontaneous result of close attention to great poetry, and which is created in the soul only by verse that is of the highest value. This emotion is founded on the Aristotelian qualities of 'the higher truth' and 'the higher seriousness,' and is inseparable from, though not to be confounded with, the mere physical delight in lovely sounds and marshalled groups of images. In this exquisite passion of poetry there is something supernatural, which evades analysis. It combines the experience of life with the hope of immortality, and fuses what has been felt and witnessed into what has only been, and can only be, imagined. The literature of all countries and of all ages has proved that this subtle and divine emotion is produced in its most direct form by the art of language rhythmically arranged, and to this art is given the name of Poetry.

The prose fragment called the *Poetics* of Aristotle is the earliest and most important treatise on the art of poetry which has come down to us from antiquity. What is commonly known as Horace's 'Art of Poetry' gives us the views of an admirable Latin writer on verse and on the poet. In 1527 Vida published his Latin poem, *Ars Poetica*, which exercised a great authority, and was by many students preferred to Horace. Of more modern interest is Scaliger's treatise, *Poetices Libri Septem* (1561). The first manual of modern Italian prosody was Girolamo Muzio's *Arte Poetica* (1551). In the England of Elizabeth we have three important treatises on the art, *An Apology for Poetry* (1595), by Sir Philip Sidney; *A Discourse of English Poetry* (1586), by W. Webbe; and *The Art of English Poetry* (1589), by George Puttenham. In France the first important treatise on the subject was the *Art Poétique Française* (1604), by Vauquelin de la Fresnaye. Nicolas Boileau, 'the Lawgiver of Parnassus,' wrote an *Art Poétique*. Among French works of the 18th century the most important are *Traité de la Prosodie Française* (1736), by Olivet, and *Réflexions sur la Poésie* (1752), by Louis Racine. Dryden's *Essay on Dramatic Poetry* belongs to 1669. Among modern works must be cited that portion of Hegel's *Ästhetik*. The *Petit Traité de Poésie Française* is greatly to be recommended. Guest's *History of English Rhythms* (1838) long remained the principal authority on English verse, but it has been completely superseded by Mr G. Saintsbury's *History of English Prosody* (1906-8, 3 vols.). Mr Robert Bridges, the Poet Laureate, has published some valuable treatises on the subject; and the work of Mr T. S. Omond (*English Metrists*, 1907) and of Mr W. J. Stone must be mentioned.

See also in this work ENGLISH LITERATURE, the sections on literature in the articles on the several countries, and the articles BALLAD, BLANK VERSE, DIDACTIC POETRY, DRAMA, ELEGY, EPIC POETRY, EPIGRAM, GNOME, HYMN, LYRIC, METRE, ODE, PASTORAL, RHYME, SATIRE, SONNET. There are separate articles on all the best-known poets.

Pogge (*Agonus cataphractus*), a small fish, not uncommon on British coasts, also known as *Armed Bullhead*, *Lyric*, *Pluck*, and *Noble*. It is related to the Bullhead (q.v.). The body, about 6 inches long, is encased by large scales; the head is very broul, and the mouth is very small. Notwithstanding its unclean appearance, it is good to eat.

Poggendorf, JOHANN CHRISTIAN, a German physicist, was born at Hamburg, 29th December 1796. He studied pharmacy, chemistry, and physics, and was professor of Physics at Berlin from 1834 till his death. In 1839 he was made a member of the Berlin Academy of Sciences. His chief discoveries were in connection with electricity and galvanism; he also invented a multiplying galvanometer for measuring the calorific action of currents. From 1824 he edited the *Annalen der Physik und Chemie*, better known as *Poggendorfs Annalen*, an important organ for the history of the physical sciences. Besides helping Liebig and Wöhler to prepare the *Dictionnaire de Chemie* (1837-51), he wrote *Lebenslinien zu einer Geschichte der exakten Wissenschaften* (1853), *Biographisch-literarisches Wörterbuch zur Geschichte der exakten Wissenschaften* (2 vols. 1857-63), and *Geschichte der Physik* (1879). He died 24th January 1877.

Poggio Bracciolini, often, but probably wrongly, called GIANFRANCESCO, a famous Italian humanist, was born in 1380 at Terranova in Florence. He was the son, not of a notary but of an apothecary Guccio, and only assumed the name of Bracciolini late in life. He studied Latin under John of Ravenna, and Greek under Manuel Chrysoloras, and early gained the notice of the Florentine scholars for his skill in copying MSS. About 1403 he became a secretary to the Roman curia; but, though the fifty years of his service covered a period of remarkable importance, he seems to have taken no interest whatever in the movement of church affairs, but to have been devoted heart and soul to the resuscitation of classical learning. In the course of his duties at the Council of Constance (1414-18) he explored the Swiss and Swabian convents for MSS., and later in his wider travels to England and elsewhere he never lost sight of the dearest interest of his life. He was able to recover MSS. of Quintilian, Ammianus Marcellinus, Lucetius, Silius Italicus, Vitruvius, and many other Roman authors. In 1453 he retired to Florence, and next year succeeded Carlo Aretino as chancellor and historiographer to the republic. Here he died in 1459. His writings include *Letters*; moral essays *On Nobility*, *On the Infelcity of Princes*, *On Marriage in Old Age* (he himself in 1435 took to wife a girl of eighteen), and the like; a rhetorical *Latin History of Florence*, in imitation of Livy; a series of unlearned and unscrupulous polemical invectives against contemporaries, especially Filelfo and Valla; and a poor translation into Latin of Xenophon's *Cyropædia*. But his most famous book is the *Liber Pæciarum*, a collection of humorous and not too decent stories and jests, written in fair Latin, and full of merry railery at the expense of the monks and secular clergy. The book has some importance in the study of the diffusion and development of folk-tales, and here Poggio takes a place with Straparola, Molini, Boccaccio, Sacchetti, and Bandello, between the later contents who have borrowed or worked up their stories on the one hand, and such earlier storehouses as the *Exempla*, the *Disciplina Clericalis*, the *Aurora Legenda*, the *Gesta Romanorum*, and the *Fabulae* on the other. A good edition (Fr. trans. and text) is that of Isidore Lisioux (Paris, 1878).

See the *Life and Letters* by Dr Walser (Leipzig, 1916 et seq.) also Voigt's *Wiederbelebung des klassischen Alterthums*, Symonds's *Renaissance in Italy*, and Sandys's *Classical Scholarship*.

Pogrom (*Russian*, 'devastation,' 'riot'), a word used, especially in the British press, with particular reference to massacres of Jews in Russia, Poland, and Eastern Europe.

Poincaré, JULES HENRI, mathematician, physicist, and philosopher, was born at Nancy, 29th April 1854. He entered the *École Polytechnique* in 1873, and became an engineer in the mining service two years later. Soon afterwards he taught at Caen, and from 1881 he was a professor in the faculty of science of Paris, exchanging the chair of mathematical physics and calculus of probabilities in 1896 for that of celestial mechanics. A member of the *Académie des Sciences* from 1887, and of the *Académie Française* from 1908, he died 17th July 1912, universally recognised as one of the greatest mathematicians of his age. See *Henri Poincaré: l'œuvre scientifique, l'œuvre philosophique* (1914) by various authors, and *Life* by Lebon (1912).

Poincaré, RAYMOND, French president and premier, was born 20th August 1860 at Bar-le-Duc, a cousin of the mathematician. Educated at Bar-le-Duc and at Paris University, he won a reputation at the bar, especially in patent and trade-mark cases, and had engaged in legal journalism and served in the department of agriculture before he was elected deputy for the department of Meuse in 1887. He was minister of public instruction and of finance in various ministries between 1893 and 1906. In the interval in his political life that followed, M. Poincaré published *Idées contemporaines* (1906) and *Questions et figures politiques* (1907), and was made a member of the *Académie* in 1909. He had been a senator from 1903. In 1912-13, as premier and foreign minister, and thereafter as an unusually self-assertive president of the republic, he followed a strongly national policy, drawing close to Russia. What part his Russian visit of 1914 had in bringing about the Great War is disputed. The war itself was fought from beginning to end under his guidance. Premier again in 1922-24, he made it his policy to wring from Germany the utmost penalty of defeat, severely straining the entente with Britain. He was responsible for the French occupation of the Ruhr basin in 1923. He took office again in 1926.

Poinciana, a small genus of Leguminosae (Caesalpinioideae), tropical trees, of which *P. regia* (the flamboyant tree) is cultivated for the sake of its flame-coloured flowers.

Poinding (same root as Eng. *pond*), in the law of Scotland, means the seizing and selling of a debtor's goods under process of law, or under the warrant of a heritable security, in order to pay the debt. It is either real or personal. Real poiding is the attaching of goods or moveables on the land over which some heritable security exists. It is one mode in which heritable security is made effectual. Thus, the superior of lands can poid the ground to obtain payment of his feu-duties; and the holder of a heritable bond can do the same in order to recover his debt. Personal poiding is the mode in which a decree of the court is made effectual by the messenger or bailiff seizing the moveables of the debtor. It may not proceed until the debtor has been charged to pay the debt and the days of charge have elapsed. The debtor's goods being poided, they are appraised or valued, and the messenger reports his execution to the sheriff, or other judge ordinary, who grants warrant to sell the goods by public roup after advertisements. The net amount of the sale is paid over to the creditor, or, if no purchaser bid for them, they are delivered to the creditor at the appraised value. There is also another kind of poiding, called a poiding of stray cattle, which takes place whenever the cattle of a stranger trespass on lands, in

which case the owner or occupier of the lands can seize them at his own hand, without judicial warrant, and keep them as a security until the damage done by the cattle is paid to the owner of the land. The poider must, however, take care to keep the cattle in a proper place, and feed them. In England the word poiding is not used, the corresponding term being Distress (q.v.).

Poinsettia, a genus of Euphorbiaceae (q.v.), better included in Euphorbia. The name is given to the Mexican shrub *Euphorbia pulcherrima*, introduced into the horticulture of other lands by Joel Roberts Poinsett (1779-1851), U.S. minister to Mexico. It is remarkable for the large and conspicuous vermilion bracts below its yellowish flowers.

Point de Galle. See GALLE.

Pointe-à-Pitre, the principal town and port, though not the capital, of Guadeloupe (q.v.), on the south-west side of Grande-Terre. It is fortified, and has some sugar-boiling. Pop. 23,000.

Pointed Architecture. See GOTHIC.

Pointer, a breed introduced from Spain about the middle of the 18th century. The Spanish pointer was a larger and much slower dog than the modern English pointer, rather wanting in stamina, and inclined to 'knock up' with a hard day's work; but, if not hurried, was possessed of wonderful nose and powers of scent. As shooting became more common, and guns approached nearer to perfection, the Spanish pointer was found to be too slow and soft. With the object of removing these defects, crosses with the greyhound to improve the speed, and with the bulldog to get courage, were tried, but with little success, until about the beginning of the 19th century the well known Colonel Thornton tried a cross with the lighter variety of foxhound. He soon succeeded in breeding a light and active dog, capable of ranging at a fast pace for a considerable time, and though possibly, not with the nose of the old Spanish pointer, yet with sufficient for the purpose. Other breeders followed suit, and a distinct strain known as the English Pointer was soon established. By careful selection the hound tendency to hunt a foot-scent was eradicated, or nearly so, while some of the speed and staying powers of the hound were retained. The act of 'pointing' when the game is first scented was at first carefully taught, but gradually became instinctive, until now well-bred puppies of a few months old may be seen pointing at any object which excites them. In general appearance the pointer somewhat resembles the foxhound, though he is a lighter and more active dog, with a finer coat. The head of the pointer should be fairly large, with an intelligent expression; a small eye or too much lip greatly detracts from the appearance. The shoulders should be sloping and powerful, as the dog has often to stop suddenly on a 'point' when at full speed. The body should be built on graceful and racing lines, chest not too wide, but very deep, feet round and compact. Liver and white, and lemon and white, are the popular colours, as they are easily seen in heather or turnips, but whole black or liver has many admirers. Owing to the changed conditions of agriculture, the pointer is not now used so extensively for partridge shooting, but is still used for grouse. In hot weather, where water is scarce, the pointer has a great advantage over the setter, but succumbs sooner to cold and wet. Seldom kept as a companion, he is not very intelligent, but he is easily kept in command, and is generally good tempered.

Pointillism, a development of Impressionism (q.v.), is a laborious method of painting, in which the colours are placed side by side in spherical points (not spots) on the canvas. The shadows,

the tone of the picture. Pointillism, used occasionally by Senrat, Signac, Pissarro, and Van Gogh, has not stood the test of time.

Poiré, EMMANUEL. See CARAN D'ACHE.

Poison is commonly defined to be a substance which, when administered in small quantity, is capable of acting deleteriously on the body; but this definition is obviously too restricted, for it would exclude numerous substances which are only poisonous when administered in large doses, as the salts of lead, antimony, &c.; hence the quantity required to kill must not enter into the definition. A good practical definition of a poison is 'any substance or matter which, when introduced into the body in any way, can destroy life by its own inherent qualities without acting mechanically.' This definition includes poisonous solids, liquids, and gases of definite chemical composition, the products of decomposition or of bacterial organisms, and the virus of contagious diseases. The last mentioned produce the symptoms of the various infectious and contagious diseases, and are not included in treatises on poisons. The others are classified sometimes according to their source, as mineral, vegetable, and animal; or more conveniently according to their action, as *Irritants*, *Narcotics*, and *Narcotico-irritants*.

The *Irritants*, when taken in ordinary doses, speedily occasion intense vomiting and purging and severe abdominal pain. They act chiefly on the stomach and intestines, which they irritate, inflame, and frequently corrode, and may thus occasion ulceration, perforation, or gangrene. Amongst those which possess corrosive properties are the strong mineral acids, caustic alkalis, corrosive sublimate, &c.; whilst among the pure irritants which exert no destructive chemical action on the tissues with which they come in contact may be mentioned cantharides. The *Narcotics* act specially on the brain and spinal cord. Amongst their most common symptoms are giddiness, headache, obscurity of sight or double vision, stupor, loss of power of the voluntary muscles, convulsions, and, finally, complete coma. These poisons have no acrid, burning taste, nor do they usually give rise to vomiting or diarrhoea, and, excepting a slight fullness of the cerebral vessels, they leave no well-marked post-mortem appearance. They are few in number, and none of them belong to the mineral kingdom. The *Narcotico-irritants* have, as their name implies, a mixed action. At varying periods after they have been swallowed they give rise to vomiting and purging, like irritants, and sooner or later produce stupor, coma, paralysis, and convulsions, owing to their effect on the brain and spinal marrow. As familiar examples we may point to monkshood, tobacco, and poisonous mushrooms. Sometimes the more violent of the poisons here classed as irritants are made into a separate group—*Corrosives*; the narcotics are put under the head *Narcotics*; and the gaseous poisons are treated as a separate class. See also PROMAINES, PYÆMIA.

Under the head of *Irritant Poisons* may be included (1) Mineral Acids, as sulphuric, nitric, and hydrochloric acids; vegetable acids, and some of their salts, as oxalic acid, binoxalate of potash, and tartaric acid (in doses of half an ounce or more); the alkalis, as pearl-ash (carbonate of potash), soap lees (carbonate of soda), ammonia and its sesquicarbonate in strong solution; and metallic compounds, as white arsenic (arsenious acid), yellow arsenic (arsenite), corrosive sublimate, permanganate and other salts of mercury, acetate of lead (sugar of lead) in doses of an ounce and upwards, sulphate of copper (blue vitriol), subacetate of copper (verdigris), arsenite of copper

green, which has been employed under the name of *extract of spinach* for colouring confectionery), tartarated antimony, chloride of antimony (butter of antimony), chloride of zinc (Sir W. Burnett's Fluid), nitrate of silver (lunar caustic), sulphate of iron (copperas or green vitriol), and bichromate of potash; (2) Vegetable Substances—viz. colocyath and gamboge in large doses, savin, croton-oil, elaterium, &c.; and (3) Animal Substances, such as cantharides, to which must be added the occasional cases in which certain fish and molluscs, usually quite innocuous, act as irritant poisons. The *Narcotic Poisons* include opium, hydrocyanic (or prussic) acid, cyanide of potassium, henbane, alcohol, ether, chloral, and chloroform. The *Narcotico-irritant Poisons* include nux vomica, meadow saffron (Colchicum), white hellebore, foxglove, common henlock, water henlock (*Cicuta verna*), water-dropwort (*Eranthis cicutæ*), fool's-parsley, thorn-apple, monkshood or aconite, deadly nightshade, tobacco, Indian tobacco (*Lobelia inflata*), the bark and seeds of the common laburnum, the leaves of the yew-tree, and certain kinds of fungi.

The cases in which there are antidotes qualified to neutralise chemically the action of the poison are few in number. For the *mineral acids* chalk or magnesia in water must be used, with the view of neutralising them, after which milk should be given freely. The *alkalis and their carbonates* must be neutralised by vinegar and water, or lemon-juice mixed with water, after which milk should be given. For *oxalic acid* the antidote is chalk or magnesia in water, by which an insoluble oxalate of lime or magnesia is formed. For *arsenic* the hydrated peroxide of iron has been regarded as an antidote, but its efficacy is doubtful. Vomiting should be excited by the administration of sulphate of zinc in warm water, and, after the stomach has been well cleared out, demulcent fluids, such as flour and water or milk, should be given. *Corrosive sublimate* combines with albumen (white of egg), and forms an insoluble inert mass. *Nitrate of silver* is neutralised by chloride of sodium (common salt) dissolved in water; *tartarated antimony* is to a great degree rendered inert by the administration of tannin; and *acetate of lead* is rendered inert by the administration of sulphate of magnesia, which converts it into an insoluble sulphate of lead. In all cases of suspected poisoning, in which the nature of the poison is not known, the safest course is at once to produce vomiting by sulphate of zinc, or in its absence by a dessert-spoonful of flour of mustard suspended in tepid water, and to continue the vomiting till all the contents of the stomach are discharged, after which milk should be given freely.

Most of the known gases have a poisonous action when inhaled into the lungs; in these cases death may be due simply to suffocation or to a specific action of the gas. *Carbonic Acid* (q.v.), although seldom employed as an instrument of murder, is a frequent cause of accidental death. It is established by numerous experiments that air containing more than *one-tenth* of its volume of carbonic acid will, if inhaled, destroy life in man and the higher animals; when diluted with two or more volumes of air it can be breathed, and produces symptoms of vertigo and somnolency, and so great a loss of muscular power that the individual, if in an erect or sitting position, falls as if struck to the ground. The respiration, which at first is difficult and stertorous, becomes suspended. The action of the heart is at first violent, but soon ceases, sensibility is lost, and the person now falls into a comatose or death-like state. Those who have been resuscitated usually feel pain in the head and general soreness of the body for some days, and in

a few severe cases paralysis of the muscles of the face has remained. The patient must, of course, be at once removed from the poisonous atmosphere, after which artificial respiration should be had recourse to. If the skin is warm cold water may be poured on the head and spine; while if the surface be cold a warm bath should be employed. When respiration is re-established venesection will often relieve the congestion of the vessels of the brain. The inhalation of oxygen gas is said to have been of service in these cases. *Carbonic oxide* is also an active poison, and is present in coal-gas and in charcoal fumes. Both carbonic acid and carbonic oxide act as powerful narcotics. The fatal power of ordinary coal-gas as an asphyxiant and irritant is probably due to the carbonic oxide present; the post-mortem appearances are very similar in cases of poisoning by coal-gas and by carbonic oxide. *Sulphuretted hydrogen*, which occurs abundantly in foul drains, sewers, cesspools, &c., is a gaseous poison whose effects are often noticed. Nothing certain is known of the smallest proportion of this gas required to destroy human life; but air containing only $\frac{1}{1000}$ th of its volume of this gas will destroy a dog; and when the gas exists in the proportion of $\frac{1}{100}$ th it will kill a horse. During the construction of the Thames Tunnel the men engaged in the work suffered severely from the presence of this gas, which was probably derived from the action of the water on the iron pyrites in the clay, and which issued in sudden bursts from the walls. By respiring this atmosphere the strongest and most robust men were in the course of a few months reduced to an extreme state of exhaustion, and several died. The symptoms with which they were first affected were giddiness, sickness, and general debility; they became emaciated, and fell into a state of low fever accompanied by delirium. In this case the dilution was extreme; when the gas is breathed in a more concentrated form the person speedily falls, apparently lifeless. It appears to act as a narcotic poison when concentrated, but like a narcotic-irritant when much diluted with air. The action of the vapour of *sulphide of ammonium*, which is also commonly present in cesspools, &c., is probably much the same as that of sulphuretted hydrogen. Many of the gases which are only found as products of the laboratory are in the highest degree poisonous, as arseniuretted hydrogen; but as few persons run the risk of inspiring them it is unnecessary to enter into details.

In point of Law, the use of poison to kill or injure a human being or certain animals renders the poisoner amenable to the criminal courts. With regard to the sale of poisons, the legislature found it necessary to put some restrictions on one description—viz. arsenic—in order to prevent persons obtaining it with facility, and in such a manner as to avoid detection. The Act 14 and 15 Vict. chap. 13, requires every person who sells arsenic to enter in his books the date and quantity and purpose of its use, and later acts apply this rule to other poisons. It is not to be sold to one who is unknown to the vendor unless in presence of a witness who is known, and whose place of abode is recorded in the book. The arsenic must also be mixed with soot or indigo, in the proportion of $\frac{1}{4}$ oz. of soot or indigo to the lb. All the boxes, bottles, &c. must be labelled 'Poison.' Those who offend as to arsenic incur a penalty of £20; but in prescriptions poisons may be used in the ordinary way by duly qualified medical practitioners. As to the restriction on the sale of other poisons, see CHEMISTS AND DRUGGISTS. The offences committed by those who administer poisons to mankind are as follows: Whoever causes death by poison commits murder, for the means are immaterial if the death was caused by such

means with a felonious intent. Where death is not caused, nevertheless whoever administers poison, or causes it to be administered to any person, with intent to commit murder is guilty of felony, and is liable to penal servitude for life, or for not less than three years. Moreover, whoever attempts to administer poison, or other destructive thing, to any person with intent to commit murder is guilty of felony, and is punishable in the same way. These offences are committed whether the poison administered or attempted to be administered, does injury or not; and it is a sufficient committing of the offence if the poison is put in such a place that a party was likely, and was intended to take it. Moreover, even though murder was not intended, but merely an intent to endanger life or inflict grievous bodily harm, still the offence is felony, and is punishable by penal servitude varying from three to ten years. There is also a similar punishment for the attempt to administer any stupefying drug. Not only is it a crime to administer or attempt to administer poison to human beings, but if cattle are maliciously killed by poison the offence is felony, punishable by penal servitude of from three to fourteen years. So to kill by poison any dog, bird, beast, or other animal, ordinarily kept in a state of confinement, is an offence punishable by justices of the peace with imprisonment for six months, or a fine of £20 over and above the injury done. If any person lay poison on lands to kill game he incurs a penalty of £10. Moreover, by the Protection of Animals Acts, whoever sells or offers to sell grain or seed which has been rendered poisonous except for *bonâ fide* use in agriculture incurs a penalty of £10. Whoever puts upon any land or building any poison, or any fluid or edible matter (not being sown seed or grain) which has been rendered poisonous, incurs a like penalty.

SECRET POISONING is a mode of taking away life by poisons so slow in their operation that the gradual sinking of the victims under their influence closely resembles the effects of disease or the ordinary decay of nature. It has been practised in all ages, and several undoubted and numerous supposed instances of it are mentioned by Greek and Roman writers. The prevailing ignorance of pathology and chemistry enabled crimes to be carried out with impunity with poisons which would be readily detected at the present day; and for similar reasons many deaths were ascribed to poison that were doubtless due to natural causes. It is impossible to attach much credence to stories such as that Henry VI. was killed by a pair of poisoned gloves, or that victims were simply got rid of by inducing them to smell a poisoned rose. And it is wholly incredible that in pre scientific days treacherous friends and hidden enemies had access to secret and mysterious methods of poisoning beyond power of detection that are denied to scientific investigators in days when we are acquainted with ten times as many and ten times as subtle poisons. In secret poisoning various preparations of arsenic seem to have been most frequently used. In the 17th century this atrocious practice became of specially frequent occurrence; and from this time it rapidly increased, spread over western Europe like an epidemic, and became gradually a regular branch of education among those who professed a knowledge of chemistry, magic, or astrology. These persons regarded the knowledge of the mode of preparing secret poisons as of the highest importance, and many of them realised large sums by the sale of their preparations, and occasionally of the secret of their composition. It was in Italy and France that this art was chiefly practised and brought to the highest perfection; but it seems

also to have prevailed in England to a considerable extent, for in 1531 the poisoning of seventeen persons, two of whom died, by the Bishop of Rochester's cook led to the passing of an act which declared the employment of secret poisons to be high-treason, and sentenced those who were found guilty of it to be boiled to death. This act was repealed in 1547.

The only undoubted instance of this crime which appears prominently in English history is the murder of Sir Thomas Overbury (q.v.) by the divorced Countess of Essex and others. Prince Henry was falsely supposed to have been poisoned by his father James I. (1612); and James's own death was similarly ascribed to nefarious practices on the part of Buckingham, nay, even of Charles I. (Milton). Undoubtedly such was the popular impression at the time, for Dr Lamb, a conjurer and quack, who was believed to have furnished Buckingham with the poisons, was seized by the angry populace in Wood Street, Cheapside, London, and beaten and stoned to death. But it was in Italy that this mode of poisoning was most prevalent. There, judging from the writings of various authors, it seems to have been looked upon as a not unjustifiable proceeding to get rid of a rival or enemy by poison; and from the time of the Lombard invasion down to the 17th century Italian history teems with instances which sufficiently show that poison was both the favourite weapon of the oppressor and the protection or revenge of the oppressed. The Borgias (q.v.) are generally singled out and held up to the horror and detestation of mankind; but as far as their poisonings are concerned they merely employed this method of destroying their adversaries a little more frequently than their neighbours. To show the popular feeling on this subject we may instance the case mentioned in the *Mémoires* of Henry II., fifth Duke of Guise, of a soldier who was requested to rid the Duke of Genaro Annese, one of his opponents in Naples. *Assassination* was the mode proposed to the soldier, but he shrank with horror from the suggestion, stating at the same time that he was quite willing to *poison* Annese. It was shortly after the date of this story (1648) that secret poisoning became so frequent; and the Catholic clergy, despite the rules of the confessional, felt themselves bound to acquaint Pope Alexander VII. with the extent of the practice. On investigation it was found that young widows were extraordinarily abundant in Rome, and that most of the unhappy marriages were speedily dissolved by the sickness and death of the husband; and further inquiries resulted in the discovery of a secret society of young matrons which met at the house of an old hag, by name Hieronyma Spara, a reputed witch and fortune-teller, who supplied those of them who wished to resent the infidelities of their husbands with a slow poison, clear, tasteless, and limpid, and of strength sufficient to destroy life in the course of a day, week, month, or number of months, as the purchaser preferred. The ladies of Rome had been long acquainted with the 'wonderful elixir' compounded by La Spara; but they kept the secret so well, and made such effectual use of their knowledge, that it was only after several years, during which a large number of unsuspected victims had perished, and even then through a cunning artifice of the police, that the whole proceedings were brought to light. La Spara and thirteen of her companions were hanged, a large number of the culprits were whipped half-naked through the streets of Rome, and some of the highest rank suffered fines and banishment. About half a century afterwards the discovery was made of a similar organisation at Naples, headed by an old

woman of threescore and ten named Toffania, who manufactured a poison similar to that of La Spara, and sold it extensively in Naples under the name of *aquetta*, and even sent it to all parts of Italy under the name of 'Manna of St Nicola of Bari,' giving it the same name as the renowned miraculous oil of St Nicola to elude discovery.

This poison, now best known as the 'Acqua Tofana' or 'Acqua di Perugia,' is said by Hahnemann to have been compounded of arsenical neutral salts; while Garelli states that it was crystallised arsenic dissolved in a large quantity of water; but both agree that it produced its effect almost imperceptibly by gradually weakening the appetite and respiratory organs. After having directly or indirectly caused the death of more than 600 persons, Toffania was at length seized, tried, and strangled in 1719. From this time the mania for secret poisoning gradually died away in Italy.

Catharine de' Medici has been frequently charged with wholesale poisoning, and in 1558 four of the Scottish commissioners who had been present at Queen Mary's marriage to the Dauphin were poisoned, it was believed, at Dieppe. But it was about the middle of the 17th century that this horrible practice seems to have become most prevalent in France. Here, too, the agents were married women, and their husbands the victims; and, as in Italy, the extent to which the practice was carried was first made known by the clergy. The government, acting on the information thus obtained, seized and imprisoned in the Bastille two Italians named Exili and Glaser, who were suspected of having been the manufacturers and vendors of the poisons. Glaser died in prison; but Exili, becoming acquainted with another prisoner named St Croix, communicated to him his secret, which the latter made considerable use of after his release, compounding in particular the poison known as 'succession powder,' which subsequently became so celebrated. It was the same St Croix who played such a prominent part in the tragical history of the Marquise de Brinvilliers (q.v.). Penantier, the treasurer of the province of Languedoc, and the Cardinal de Bonzy were both pupils of St Croix, and managed, the one to pave the way for his own advancement, and the other to rid himself of his numerous creditors by the administration of poison; but the great influence of these men and the want of direct evidence barred all proceedings against them. Secret poisoning now became fashionable; the passions of jealousy, revenge, avarice, and even petty spite were all satisfied in the same way, and as a necessary consequence other offences decreased in proportion. The prisons teemed with suspected criminals, and the 'Chambre Ardente' was instituted for the special purpose of trying these offenders. In Paris this trade was chiefly in the hands of two women named Lavoisin and Lavignon, who combined with the ostensible occupation of midwife that of fortune-teller, and foretold to wives the decease of their husbands, to needy heirs that of their rich relatives, taking care at the same time to be instrumental in fulfilling their own predictions. Their houses were frequented by numbers of all classes, both from Paris and the provinces, among whom were the celebrated Marshal de Luxembourg (q.v.), the Duchess de Bouillon, and the Countess de Soissons; the two former of these, however, went merely from curiosity. Lavoisin and her confederate were at last discovered, tried, condemned, and burned alive in the Place de Grève, 22d February 1680; and from thirty to fifty of their accomplices were hanged in various cities of France. So common had this atrocious practice been that Madame de Sévigné, in one of her letters, expresses a fear lest the terms

'Frenchman' and 'poisoner' should become synonymous. For two years after the execution of the two Parisian poisoners the crime continued to be largely committed, being fostered by the impunity with which offenders of high rank were allowed to escape; and it was not till more than a hundred persons had died at the stake or on the gallows that the government succeeded in suppressing it. The mania for secret poisoning has not since been revived to the same extent, though isolated instances of its practice have occasionally been discovered, particularly in Hungary, where, within the last half of the 19th century, very extraordinary disclosures were at different times made of the prevalence of this frightful crime among the peasant women. During the times of slavery the Ohi men among the negroes in the West Indies were credited with being expert poisoners. They used vegetable poisons obtained from plants, and there can be no doubt were often instrumental in getting rid of tyrannical or otherwise objectionable masters. In Britain famous poisoning trials have been those of W. Palmer (three victims, 1856), Madeleine Smith ('not proven,' 1857), E. W. Pritchard, M.D. (two victims, 1865), Mary Ann Cotton (sixteen victims, 1872), G. H. Lanson, M.D. (1882), P. Cross, M.D. (1887), Mrs Maybrick (1889), H. H. Crippen (1910).

Poisson, SIMÉON DENIS, was born at Pithiviers, in Loiret, 21st June 1781; and received into the Ecole Polytechnique in 1798, attracted the notice of Lagrange and Laplace, both of whom anticipated for him a brilliant career. In 1802 he became a professor in the Polytechnique; in 1808 a member of the Bureau des Longitudes; in 1809 professor in the Faculty of Sciences; member of the Institute in 1812, &c.; and in 1837 a peer of France. He died 25th April 1840. Poisson's whole life was devoted to the prosecution of scientific research, and the fruits of his pen number about 300 Memoirs, inserted in the publications of the Ecole Polytechnique, of the Academy of Sciences, and other scientific journals. Of the separate treatises published by Poisson the best known is the *Traité de Mécanique* (2 vols. 1833); others were on capillary action, the mathematical theory of heat, the motion of projectiles, and, lastly, the celebrated work *Sur l'Invariabilité des moyens Mouvements des grands Axes Planétaires*. Poisson is fairly considered one of the chief founders of the science of mathematical physics.

Poitiers, the capital of the French department of Vienne, occupies the summit and slopes of a little eminence, round whose base flow the Chain and the Boivre, 61 miles SSW. of Tours. Before the revolution it had an immense number of religious edifices, which even yet are sufficiently numerous. The most interesting are the little Temple de St Jean, originally a baptistery of the 6th or 7th century; the abbey church of St Radegonde, with the saint's cenotaph, much visited by pilgrims; and the noble cathedral of St Pierre (1161-15th century), in which, or in the older edifice that occupied its site, twenty-three councils were held—the first in the 4th, and the last in the 15th century. Other edifices are the Palais-de-Justice (the palace formerly of the Counts of Poitou) and the Hôtel-de-Ville (1876). A university, founded

by Charles VII. in 1431, as now reconstructed has the three faculties of law, of science, and of literature. There are besides a public library, a museum, and several learned societies. Pop. (1872) 28,247; (1891) 34,374; (1921) 37,663. Poitiers, the *Lemonum* of the Romans, derives its present name (earlier *Poitiers*) from the Pietavi or Pictones. In and around it are numerous Celtic and Roman remains, a dolmen, baths, some fragments of a huge amphitheatre, &c.; and here in 1882 the remains of a whole Gallo-Roman town were discovered, with temple, baths, and streets, spread over 14 acres. In the vicinity Alarie II., the Visigoth, was defeated and slain by Clovis in 507; and somewhere between Poitiers and Tours Charles Martel won his great victory in 732 over the Saracens under Abd-ur-Rabman. Later still (on 19th September 1356), somewhat to the south-east of Poitiers, Edward the Black Prince, with some 12,000 or 14,000 Englishmen and Gascons, defeated 60,000 of the troops of King John of France, killing 11,000 and taking more than 2000 prisoners, among these the monarch himself and one of his sons. St Hilary (q.v.) was the first bishop of Poitiers, which long was capital of the province of Poitou. From this town the ancient family took its name to which Diana of Poitiers (q.v.) belonged.

Poitou, a former province of south-western France, coincident with the present departments of Deux Sèvres, Vendée, and Vienne. It was divided into Upper and Lower Poitou, and had for its capital Poitiers. Its early history is the same as that of Aquitania (q.v.). Poitou became a possession of the English crown when Eleanor, Countess of Poitou and Duchess of Aquitaine, married (1152) Henry of Anjou (see HENRY II.). Philip Augustus reconquered it in 1205. In 1360 it reverted to England, but nine years later was retaken by Charles V.

Poke (*Phytolacca decandra*), an American branching herb of the Phytolaccaceae, with racemes of white flowers and deep-purple berries (Inkberries or Pigeonberries). For Indian Poke see HELLEBORE.

Poker, a round game at cards (developed from the older game of brag). Each player has five cards dealt him. A sum called the *ante* is deposited by the oldest hand. The players then look at their hands, each in order after the ante saying whether he will play or pass. If he passes he throws down his cards and stakes nothing. If he plays he has to *chip to full*—i.e. to stake a sum equal to twice the ante; the amount clipped by the ante, if he plays, or *makes good the ante*, is only equal to his first stake. Each player in rotation may then discard any of his cards and receive from the dealer an equal number of cards from the top of the pack, but no one is obliged to discard any. When all have filled, each player in order must either raise his cards or go out of the game, forfeiting what he has already staked. The *raise* is generally limited, but any less sum than the limit may be staked. Subsequent players must either *see the raise*—i.e. make the sum next staked equal to that of the last raiser—or *go better*—i.e. raise higher, or go out of the game. The raising, seeing, going better, or going out, as the case may be, continues until either all the players but one have gone out (when the one left in takes the pool), or until all the stakes of all the players left in are equal, no one going better. Then a *call* is declared. The player to the left of the one who compelled a call has then to show, face upwards, the best combination he holds which has a poker value. The subsequent players in order either show anything they have better, or throw down their hands. The best poker hand takes the pool.

In case of absolute equality the pool is divided. The value of the hands is as follows, beginning with the best: (1) *Straight flush*, sequence of five cards of the same suit; (2) *Four*, four cards of the same rank, accompanied by any other card; (3) *Full*, three cards of the same rank, and a pair; (4) *Flush*, five cards of the same suit, not in sequence; (5) *Straight*, sequence of five cards not all of the same suit; (6) *Triplets*, three cards of the same rank, not accompanied by a pair; (7) *Two pairs*; (8) *One pair*; (9) *Highest card*. The cards rank as at whist (ace highest), except in the case of straights, when ace may be highest or lowest—i.e. ace, king, queen, knave, ten, or five, four, three, two, ace form the highest and lowest straights respectively. If more than one player holds a straight flush the sequence headed by the highest ace wins; the same as between two straights. Similarly, the highest fours win, or the highest triplets in triplet hands; in the case of fulls, the holder of the highest triplets wins. As between two flushes, the highest card wins; if these tie, the next highest, and so on. If two players each hold two pairs, the highest pair wins; if the two pairs tie, the remaining highest card wins; with one pair, the same. If none of the players remaining in the game hold any of the above combinations, each shows his highest card; if there is a tie, the next highest, and so on. There are numerous varieties in the way of playing, for which treatises on poker should be consulted. The above describes the simplest form of *Draw Poker*.

Poker-drawings, the name given to designs (after well-known pictures generally) burnt into lime tree or other wood with 'pokers,' which rather resembled plumbers' soldering-irons. The chief 'poker,' 'pyrotechnic,' or 'pyrographic' artists were John Cranch (1751-1823), Smith of Skipton, and Dr Griffiths, the master of University College, for whose chapel he executed an altar-piece after Carlo Dolce. At Knowsley are two poker drawings ascribed to Salvator Rosa. A similar process, for adorning ships' cabins, table tops, &c., was patented in 1865.

Pokhurn (*Pokaran*), a town of India, in the Rajput state of Jodhpur, 79 miles NW. of Jodhpur; pop. 4400.

Pola, a city of Istria, now belonging to Italy, and formerly the most important naval station of Austria-Hungary, is situated near the southern extremity of the peninsula of Istria, 105 miles by rail S. of Trieste. The harbour is thoroughly sheltered, deep, and spacious enough to accommodate the largest fleet. The town is protected by forts and batteries, and is overlooked by the citadel, by which it and the bay are commanded. The cathedral dates from the 15th-18th century. Pola is also a shipping port, exporting wood, fish, sand, and building stones, and importing provisions, coal, and bricks. Pop. (1851) 1100; (1900) 45,205, of whom 7700 belonged to the garrison; (1921) 58,562. Founded traditionally by the Colchians who were sent in pursuit of Jason. Pola became a colony of Rome under Sulla, and was reformed by Augustus under the name of *Pictas Julia*. At the beginning of the 3d century it had 30,000 inhabitants, and was a station of the Roman fleet. It was destroyed in 1267 by the Venetian masters, who had conquered it in 1148; and in 1379 the Genoese, after routing the Venetians in a sea fight off the town, once more ravaged it. But it only passed from Venice in 1797 to Austria, who chose it as her chief naval harbor in 1848. It contains numerous interesting Roman remains, among them a well-preserved amphitheatre, 450 feet long and 360 broad. Two temples, one dedicated to Rome

and Augustus, a few remains of a theatre, and several ancient gates are also extant.

Polabians, an ancient Slavonic people of the same group as the Poles, occupying the basin of the Lower Elbe. They have long been Germanised, and their language is now extinct. The term is sometimes used in a wider sense for all Slavonic peoples west and north-west of the Oder and the Erzgebirge. See SLAVONIANS.

Polacca, a species of vessel in use in the Mediterranean, with three masts and a jib-boom: the fore- and main-masts being of one piece ('pole-masts'), and the mizzen-mast with a top and top-mast.

Polacca. See POLONAISE.

Poland, a republic of Europe, till 1795 a kingdom, and thereafter till 1918 merely a geographical region of historical and ethnographical import. It lies between Germany and White Russia, between Czechoslovakia and Lithuania. In the south-east it touches the Rumanian territory of Bukovina; in the north-east it sends a broad northward arm to meet Lettland (Latvia); in the north-west a narrower arm reaches between East Prussia and the rest of Germany to the Baltic, where on its scanty seaboard a Polish port is under construction adjoining the free city of Danzig. The area is 149,359 square miles. The population at the census of 1921 for the capital and counties (*województwa*) is shown in the following table:

County	Area in sq. miles	Population (in census of 1921)
City of Warsaw	47	936,016
Warszawa (Warsaw)	11,273	2,112,106
Łódź	7,321	2,550,554
Kielce	9,898	2,535,730
Łublin	11,985	2,087,967
Białystok	12,553	1,303,437
Wilno (Vilna)	10,957	982,659
Nowogródek	8,854	822,106
Włocław (Vlodyma)	11,652	1,437,907
Polesie	16,951	879,925
Poznań (Posen)	10,232	1,947,057
Pomorze	6,302	939,195
Kraków (Cracow)	6,711	1,990,339
Łwów (Lemberg)	10,394	2,717,886
Stanisławów (Stanislaw)	7,065	1,548,580
Tarnopol	6,240	1,128,520
Śląsk (Silesia)	1,628	1,126,628
Military forces	—	318,452
Total	149,359	27,192,674

After Warsaw, the capital, the principal towns are Łódź (452,079), Lemberg or Lwów (219,388), Cracow (181,700), Posen or Poznań (160,793), and Vilna or Wilno (128,954), which the Lithuanians claim. Except on its southern border, where the Tatras (Tatry) and Beskid mountains (parts of the Carpathians) rise above 8000 feet, Poland belongs to the great European plain. It is crossed from south to north by the watershed, of no great height, between the rivers of the Baltic and the Black Sea. The Vistula (Wisła) is its great waterway, and drains nearly half of the country. About a third belongs to the basins of the Dnieper, Dniester, and Danube; the rest to those of the Oder, Niemen, Dwina, and other Baltic streams.

The kingdom of Poland, during the period of its greatest extent, after the addition of the grand-duchy of Lithuania at the close of the 14th century, was subdivided, for purposes of government, into about forty palatinates (Pol. *województwa*), which were mostly governed by hereditary chiefs. The people were divided into two great classes—nobles and serfs. The noble class, which was the privileged and governing class, included the higher nobles, the inferior nobles (a numerous class, corresponding to the knights and gentry of other countries), and the clergy, and numbered in all 200,000; the serfs formed the agricultural labourers,

and were attached to the soil. Their condition is described by all travellers as a very pitiable one. Such trade as the country had was mostly in the hands of the Germans and Jews. The nobles were the proprietors of the soil, and appropriated the larger portion of its products, the serfs being left with a bare maintenance. The former were brave and hospitable, but quarrelsome, and generally preferred their own interests to that of their country; the serfs (originally called *Kniesci*; Lat. *Knietones*) were sunk in poverty and ignorance.

Under partition the Poles were subject to rns-sianising and germanising. In Russian Poland the Orthodox Church was upheld by force. Under Austria the Poles of Galicia were better pleased, and were able to prevail over the Ruthenians. Emerging from the Great War with strong nationalist feelings and powerful friends, Poland has been more successful than some of her neighbours in her claims to territory, and her bounds are wider than ethnological considerations might lead one to expect. According to Polish statistics Poles form rather more than two-thirds of the population of the republic, Ruthenians and White Russians are more numerous than Poles in Eastern Galicia, in the territories wrested by war from Russia in 1920, and (with Lithuanians) in the Vilna region seized in the same year. The German population has been reduced to about one-half by emigration; but Germans still number over a million, especially in the towns and in the west of Jews there are over 2 millions. They form a fourth of the population of the city of Warsaw. Inequalities have been legally levelled by the constitution of 1921. The land problem was one of the first tasks of the new state, and a number of acts, notably one of 1925, deal with the breaking up of great estates. Meanwhile differences in birthrate are rapidly making Poland more Polish.

Constitution, &c.—The constitution was adopted in 1926. Citizens, male and female, of twenty-one years or more, domiciled in their constituencies, elect a Diet (*Seym*), and those of thirty a Senate, both for five years, by rules of proportional representation. The two houses together elect a president for seven years. Ministers are responsible to the Diet. In administration and local government there are naturally considerable differences in heritage from Russia, from Prussia, and from Austria, and the presence of national minorities calls for autonomy. A separate *Seym* has been set up in Silesia; and parliamentary sanction has been given to a like policy in the counties of Lemberg, Stanisławów, and Tarnopol, in each of which power is to be divided between a Polish and a Ruthenian chamber. Some of the other counties have councils. Each has a *wojewoda* (voivode or governor) appointed by the president of the republic. A commission has been appointed to unify the judicial systems. Military service is compulsory. The peace strength of the army is about 250,000. There is a small navy (about 2000 men).

Religion and Education.—The constitution lays it down that 'The Roman Catholic creed being the creed of the majority of the people, shall have a preponderating authority in the state among other religions which shall enjoy equal treatment.' A Concordat with the Vatican in 1924 arranged for reorganisation of the Roman Catholic Church. Poland is divided into five provinces; the archbishop of Gnesen and Posen is primate of all Poland. The Greek-Ruthenian Catholics and the Armenian Catholics have each an archbishop at Lemberg. The Orthodox Church includes about one-fifth of the population. Formerly under the

patriarch of Moscow, it has been autocephalous since 1924. Its metropolitan is at Warsaw. There are five state universities—Warsaw, Cracow, Lemberg, Posen, Vilna; two 'free' or private—Warsaw and Lublin; polytechnics at Warsaw and Lemberg; schools of arts, mining, agriculture, &c.

Industries.—An unusually great proportion of the population lives by agriculture. The soil is mostly a light fertile loam, well adapted for cereals, though here and there occur extensive barren tracts of sand, heath, and swamp, especially in the eastern districts. Much of the fertile soil is rich pasture-land, and much is occupied with forests of pine, beech, birch, oak, &c. Rye, oats, wheat, barley, and other cereals, potatoes, sugar-beet, hemp, timber, honey and wax, cattle, pigs, sheep, and horses, coal, salt, petroleum, natural gas, iron, and some other minerals, constitute the natural riches of the country. The coal is mined chiefly in the Dąbrowa, Cracow, and Silesian fields; salt comes from the mines and springs of Galicia (where Wieliczka is famous) and of Posen. The Eastern Galician oilfield has added to international difficulties. Industries, besides those obviously connected with these products (as oil and sugar refining, paper-making, distillation of potato spirit), include the making of cotton, machinery, various chemicals, glass, lime, and much else.

History.—The Poles are ethnologically a branch of the Slavs (q.v.). The name appears first in history as the designation of a tribe, the Poliani, who dwelt between the Oder and the Vistula, surrounded by the kindred tribes of the Masovii, Kujavii, Cuiobates, Silesians, Obotrites, and others. In course of time the name Poliani became predominant. There is no real Polish history till the reign of Mieczysław (962-992); up to the period of this sovereign we have only fables. He became a convert to Christianity, and Poland took rank as one of the political powers of Europe. Mieczysław acknowledged himself to be the feudatory of Otto of Germany. In his time the first Polish bishopric was founded at Posen. He was succeeded by his son Bolesław I. (992-1025), who extended his kingdom beyond the Oder, the Carpathians, and the Dniester. He was recognised as king by the German emperors. After a period of anarchy he was succeeded by his son Casimir (1040-58), whose reign, and that of his valiant son Bolesław II. (1058-1101), although brilliant, were of little real profit to the country. The latter monarch having murdered the Bishop of Cracow with his own hand, Poland was laid under the papal interdict, and the people absolved from their allegiance, whereupon Bolesław fled to Hungary. For two hundred years from this time Poland was only a duchy. Bolesław III., surnamed the 'Wry-mouthed' (1102-39), an energetic monarch, annexed Pomerania.

In the time of Casimir II. (1177-94) we have the senate established, which was formed from the bishops, palatines, and castellans. His death was the signal for a contest among the various claimants for the throne, which was speedily followed, as usual, by a division of the country, and during this disturbance Pomerania emancipated itself from Polish rule. In 1226 the Teutonic Knights were summoned by the Duke of Masovia to aid him against the pagan Prussians; but they soon became as formidable enemies to Poland as the Prussians, and conquered a large part of Podlachia and Lithuania. The Mongols swept over the country in 1241, committing great devastations, and defeated the Poles in a battle at Liegnitz. Many districts of the country were now colonised by Germans, and numbers of Jews took refuge in Poland. The Germans obtained great privileges from the Polish king, and were governed by the *Jus Magdeburgicum*. The reign of Ladislaus Lokietek ('the

Short³) is important (1305-33), because in his reign the first Polish diet (1331) was summoned at Checin. In conjunction with Gedymyn, Grand-duke of Lithuania, a vigorous war was carried on

king thus possessed but little power beyond what his personal influence gave him.

Sigismund I. (1506-48), also son of Casimir IV., had a long and prosperous reign, Poland being at

that time the dominant country of eastern Europe. Very different opinions have been held about this monarch, some Polish historians praising his government, while Bobrzynski and others consider him to have been a weak man. His court was filled with factions fomented by his wife, Bona Sforza, daughter of the Duke of Milan, a malignant and avaricious woman. The doctrines of the Reformation penetrated to Poland, and were a source of fresh discontents. In a war with Basil, the Grand-duke of Russia, Sigismund lost Smolensk, but he was partly compensated by obtaining lordship over Moldavia. In 1529 Sigismund issued a legal code for Lithuania

against the Teutonic Knights. His son, Casimir the Great (1333-70), increased the prosperity of Poland. Commerce was active, and Danzig and Cracow joined the league of the Hansa. In 1347 was enacted the celebrated Statute of Wislica, the foundation of Polish law: in this reign also Galicia was united to Poland. With Casimir the dynasty of the Piasts became extinct, after a rule of 510 years, according to the old Polish chroniclers. His nephew, Louis, king of Hungary, succeeded him by the will of the deceased monarch and the election of the diet. On his death without male heirs the succession fell to his daughter Jadviga or Hedwig, who was induced by the diet to marry Jagiello, Grand-duke of Lithuania, who founded the dynasty of the Jagellons (q.v.; 1386-1572), and first united Lithuania and Poland, thus doubling the extent, though not the population, of the kingdom. In 1410 the Teutonic Knights were defeated at the battle of Grünwald. His son, Ladislaus, who was also chosen king of Hungary, fell at the battle of Varna in 1444 fighting against the Turks. Casimir, who succeeded, recovered West Prussia from the Teutonic Knights and compelled them to do homage for East Prussia. In 1454 was held the diet of Nieszawa, at which the celebrated statute was enacted which conferred great privileges upon the Polish nobility. The brief reigns of Casimir's two sons were marked only by the increased power of the diet, which had by this time absorbed all but the symbols of supreme authority, and had turned Poland from a monarchy into an oligarchy. The

ania in the White-Russian language, which forms an important monument of Polish law. In 1537 occurred the first *rokosz*, or rebellion of the nobility against the kingly authority. Sigismund was about to set out to Wallachia, and was obliged to make several concessions before they would accompany him. In 1548 the king died at the advanced age of eighty-two.

He was succeeded by his son, Sigismund II. (1548-72), otherwise called Sigismund Augustus, but this prince was not elected till a debate had taken place about his marriage. He had secretly espoused as a widow a widow of the great house Radziwill, and the nobles required the union to be annulled, because they fancied that the country would gain more by a foreign alliance. Sigismund, however, carried his point, and his wife was crowned in 1550, but died soon after, not without suspicions of having been poisoned by her mother-in-law, Bona, who in this reign left Poland for her native country, carrying with her a vast amount of treasure. The quarrels between Protestants and Romanists now raged fiercely, and the Reformed faith spread rapidly in Poland. We hear of persons being burned to death for their adhesion to it. Sigismund showed great indecision in the matter. In 1569, by the diet of Lublin, Lithuania was finally joined indissolubly to Poland, and from this time there was to be but one diet for the united realm, and Warsaw, for greater convenience, became the capital. Poland also gained Livonia. In 1572 the king died. In the diet held the year after

at Warsaw it was enacted that there should be toleration for all religious opinions, but the nobles were still to have power over their serfs in spiritual matters.

The population almost doubled itself, but the nobles became every year more impatient of restraint, and the crown was now virtually elective. The members of the diet, consisting of the palatines and the *posdy*, or deputies of the lesser nobility, together with the higher nobility, sat in one chamber. The king had the right of summoning the diet, which only lasted for six weeks, and its decisions were required at a later stage, as we shall see, to be unanimous. This idea of unanimity in voting is thoroughly Slavonic, and is to be found in the old Russian folk-moots. The right of forbidding the passing of any measure was called in Poland the *liberum veto* (in Polish, *wie pozwalam*), and brought all legislation to a standstill. It was employed by many of the corrupt Polish nobles to avoid the detection of their malpractices or to gratify their private malice, and hastened the ruin of the country.

The diet of 1573 elected Henry of Valois (III. of France, q.v.), a worthless man, who fled in the most indignant fashion from the country after a reign of about five months, and was succeeded by Stephen Batory (1575-86), voivode of Transylvania, one of Poland's best kings, who carried on war successfully against the Russians, and compelled Ivan IV. to sue for peace; he also organised the Cossacks of the Ukraine into regiments of frontier soldiers. Batory, who had no heirs, was succeeded by Sigismund III. (1586-1632), the son of Catharine, sister of Sigismund II., who had married John Vasa, king of Sweden. He signed the *pacta conventa*, as the agreement between the Poles, and their king was named, and an alliance offensive and defensive was made between Poland and Sweden. Constant disputes took place between the king and the diet, and he was a great persecutor of the Dissidents, as the Protestants were called. Sigismund assisted the claims of the false Demetrius, who was assassinated at Moscow in 1606, and we find the Poles afterwards taking that city and causing Ladislaus, the son of Sigismund, to be crowned tsar; but he was soon obliged to resign, and ultimately the family of the Romanovs ascended the throne of Russia in the person of Michael. Sigismund III. died in 1632, and was followed by his sons Ladislaus IV. (1632-48) and John Casimir (1648-68). During the reign of this dynasty Wallachia and Moldavia were taken by the Turks from the Polish protectorate, Livonia was conquered (1605-21) by Sweden, and Brandenburg established itself in complete independence (1657). In 1652 Siemski, the deputy for Upita, first put an end to the diet by the *liberum veto*. The Cossacks had been goaded into rebellion by oppression and religious persecution, as they were members of the Greek Church, and finally went over to Russia in 1654. This occurred in the unfortunate days of John Casimir; and during the same reign Poland was attacked simultaneously by Russia, Sweden, Brandenburg, and the Cossacks; the country was entirely overrun, Warsaw, Wilno, and Lemberg taken, and the king compelled to flee into Silesia. Many of the Polish nobles behaved with great treachery, but the invaders were finally driven out. In 1660 Livonia was ceded to Sweden. In 1667, by the treaty of Andruszowo, the territory beyond the Dnieper was ceded to Russia. John Casimir abdicated in 1668, and retired to France, where he died in 1672.

Michael Wisniowiecki (1668-74), son of a famous general, but a weak and very insignificant man, was elected king—it is said almost against

his own will. He was a mere puppet in the hands of his subjects. A war with Turkey was concluded by the ignominious peace of Buczacz in 1672, by which the town of Kamieniec remained in the hands of the Ottomans. But the senate rejected the treaty; the Polish army was reinforced, and the command given to the celebrated John Sobieski, who routed the Turks at Choczim the following year. Michael died suddenly in 1674. After some dissensions concerning the election of a successor, John Sobieski (q.v., 1674-96) was chosen, but his reign, although adorned by the splendid triumph at Vienna (1683), was productive of little good to his country, chiefly through the continual dissensions of the nobles. As Sobieski's successor the Prince of Conti was legally elected and proclaimed king; but Augustus II. of Saxony, whose cause was supported by the House of Austria, entered Poland at the head of a Saxon army, and succeeded in obtaining the throne. Augustus showed little sympathy with his Polish subjects; he promised to reconquer for Poland her lost provinces, but this promise was chiefly made as an excuse for keeping his Saxon army in the country, in violation of the *pacta conventa*. His war with the Turks restored to Poland part of the Ukraine and the fortress of Kamieniec; but that with Charles XII. brought nothing but misfortune. Cracow was taken in 1702; Augustus was deposed, and Stanislaus Leszczynski, palatine of Posen, elected in his place. All the courts of Europe acknowledged Stanislaus, except that of Peter the Great; and, when the latter defeated Charles at the battle of Pultowa in 1709, Leszczynski was compelled to leave the country, and Augustus returned. In this reign Poland lost Courland, one of its fiefs, which was given by the Empress Anna to Biron, her favourite. Religious fanaticism was also rampant. The Dissidents were very much persecuted, and a riot having taken place in 1724 at Thorn, several of the leading citizens, including the burgomaster, were put to death. In 1733 a law was passed excluding them from all public offices. This same year the contemptible Augustus died. At the instigation of some of his supporters, Stanislaus Leszczynski, who was then residing in Lorraine, was induced to return to Poland and was elected king; but his election was opposed by Austria and Russia, and in his place was chosen Augustus III. (son of the last sovereign), a weak and incapable man. The condition of the country was now deplorable. Towards the end of his reign the more enlightened Poles, seeing the radical defects of the constitution, the want of a strong government, and the dangers of the *liberum veto*, entered into a league for the establishment of a well-organised hereditary monarchy. The conservative party, however, was strong, and relied on Russian influence, while the reformers supported the Jesuits in their exclusion of dissenters from public offices. In 1764 Stanislaus Augustus Poniatowski was elected king, chiefly through the intrigues of the Empress Catharine. Although a man of refined manners, he was weak, and not fitted to serve the country at such a crisis. The reforming, or Czartoryski party (so called because it was headed by a member of this celebrated family), had succeeded in abolishing the *liberum veto*, and effecting many other improvements; but they at the same time more severely oppressed the Dissidents, whom the Russians pretended to protect.

The Confederation of Bar (so called from Bar in Podolia) was now (1768) formed by a few patriots, an army of about 8000 men was assembled, and war declared against Russia. But they were not successful, and a bold attempt to carry off the king also failed. Frederick the Great of Prussia, who had formerly gained the consent of Austria to a partition of

Poland, made the same proposal to Russia in 1770, and in 1772 the first partition was effected. The territories seized by the three powers were as follows:

	English sq. miles.	Population.
Russia	42,000	1,800,000
Prussia	13,000	416,000
Austria	27,000	2,700,000

The whole country was now aroused to a sense of its danger; and the diet of the diminished kingdom laboured to amend the constitution. In 1788 a remarkable diet was opened which lasted four years. Many changes were introduced. The *liberum veto* was formally suppressed, and the throne was declared hereditary. The burghers were to send deputies to the diet on the same terms as the nobles; the peasants were not set free, but their condition was improved; and the Dissidents were granted complete toleration, although the Roman Catholic was declared to be the dominant religion. In this they were encouraged by Prussia, whose king, Frederick-William, swore to defend them against Russia. The new constitution was promulgated May 2, 1791. But some of the nobles were discontented at the loss of their privileges by the new order of things, and formed in 1792 the Confederation of Targowica (q.v.), and at their instigation Russian troops invaded Poland and Lithuania. Prussia now joined the Russians, and a second fruitless resistance to the united troops of Prussia and Russia, which was headed by Joseph Poniatowski (q.v.) and Kosciusko (q.v.), was followed by a second partition (1793) between those two countries as follows:

	English sq. miles.	Population.
Russia	96,000	3,000,000
Prussia	22,000	1,100,000

which the diet was forced to sanction at the point of the bayonet. The Poles now became desperate; a general rising took place (1794), the Prussians were compelled to retreat to their own country, and the Russians were several times routed. But Austria now appeared on the scene; her army advanced, and fresh Russian troops also arrived. Kosciusko was defeated at the battle of Maciejowice and taken prisoner. Suvorov (Suwarow), the Russian general, took Warsaw, and the Polish monarchy was at an end. The third partition (1795) distributed the remainder of the country as follows:

	English sq. miles.	Population.
Russia	13,000	1,200,000
Prussia	21,000	1,000,000
Austria	18,000	1,000,000

Eng. sq. m.	Pop.
Russia	220,500
Prussia	26,000
Austria	37,000

Cracow, with a small surrounding territory, was declared independent under the protection of Austria. Alexander I. gave the Poles a constitution, including biennial diets, a responsible ministry, a separate army, and liberty of the press. General Zajacek was appointed viceroy, and the Grand-duke Constantine took command of the army. For some time matters seemed to go on smoothly, but a spirit of discontent soon developed itself. Complaints were made that the freedom of the press was interfered with, and secret societies were formed. An insurrection broke out in November 1830; the grand-duke was obliged to quit the city, and General Chlopicki was appointed dictator. Early in 1831 a large Russian army, under Diebitsch, entered the country. Chlopicki resigned his dictatorship, and Prince Czartoryski was appointed president of the provisional government. From January 1831 till 8th September of the same year a series of sanguinary engagements

King Stanislaus resigned his crown, and died at St Petersburg in 1798. He lies buried in the Roman Catholic church there.

The main causes of the fall of Poland appear to have been (1) the want of patriotism and cohesion among the nobles, each pursuing his own interests, and the country thus being divided among a number of petty tyrants; (2) the want of a national middle class, the trade of the country being almost entirely in the hands of Jews and Germans; (3) the intolerance of the Jesuits, who persecuted on the one hand the Dissidents, which caused them to sympathise with Prussia, and on the other persecuted also the Orthodox inhabitants of the eastern provinces and the Cossacks, who thus looked to Russia; (4) in a less degree than the first three causes, the weakness of character of the kings—though with such a turbulent nobility it must be confessed that they had no fair play; (5) the want of natural frontiers.

The subsequent success of the French against the Russians and the promises of Napoleon to reconstitute Poland rallied round him the Poles, who distinguished themselves in several campaigns against their old enemies; but all that Napoleon accomplished in fulfilment of his promise was the establishment, by the treaty of Tilsit (1807), of the duchy of Warsaw, chiefly out of the Prussian share of Poland, with a liberal constitution and the Elector of Saxony as its head. In 1809 Western Galicia was taken from Austria and added to the duchy, but the advance of the allied army in 1813 put an end to its existence. After the cessions by Austria in 1809 the duchy contained 58,290 English sq. m., with a population of about 4,000,000. Danzig was also declared a republic, but given back to Prussia (February 3, 1814).

The division of Poland was rearranged by the Congress of Vienna in 1815; the original shares of Prussia and Austria were diminished, and that part of the duchy of Warsaw which was not restored to Prussia and Austria was united as the kingdom of Poland to the Russian empire, but merely by the bond of a personal union (the same monarch being the sovereign of each), and the two states being wholly independent of each other. The remaining parts of Poland were incorporated with the kingdoms which had seized them. The partition of Poland as thus arranged was as follows:

Political Divisions before Restoration.

Provinces of Courland, Vitebsk, Grodno, Minsk, Mohilev, Volhynia, Kiev, Podolia, and the Kingdom of Poland (see below). Of these portions of the original kingdom of Poland belonging to Russia it must be remarked that Courland was ceded to Russia in the reign of Catherine by the free action of the inhabitants; Kiev had belonged to Russia by conquest since 1667. Posen, most of West Prussia, and several districts of East Prussia, Galicia, Bukowina, Zipse, &c.

took place, in which the Poles were at first successful. On the 8th of September, however, Paskevitch (q.v.), who had succeeded Diebitsch, took Warsaw, and the insurrection was virtually at an end. The Poles had not succeeded in obtaining any assistance from foreign powers. From this time the independence of Poland was suppressed, and in 1832 it was declared an integral part of the Russian empire, with a separate administration, headed by a viceroy chosen by the tsar; the constitution was annulled, and a strict censorship of the press was established. Many of the literary treasures were carried off to the public library of St Petersburg. Slight outbreaks occurred in 1846, which were severely repressed. Simultaneous disturbances in the Prussian and Austrian portions of Poland met with the same fate. Their leaders in Prussia were imprisoned, but released by the revolution of 1848 at Berlin. In no part was the work of denationalisation more complete than in

Prussian Poland. It proceeded quietly, but thoroughly. In Galicia the peasants at the same time massacred many of the nobles. On the 6th of November 1848 the republic of Cracow was incorporated with Austria.

After the accession of Alexander II. in 1855 the condition of the Poles was considerably ameliorated. An amnesty brought back many of those who had been expropriated, and various other reforms were hoped for. On the 29th November, on the thirtieth anniversary of the insurrection, many political manifestations took place, both in the churches and elsewhere. On these occasions riots took place, and some persons were unfortunately killed. Warsaw was now declared in a state of siege. In June 1862 an attempt was made to assassinate General Liders, the governor, who was succeeded by the Grand-duke Constantine, the brother of the emperor, the Marquis Wielopolski being appointed chief minister. Meanwhile Alexander II. had made great concessions; the public offices of the country were to be filled by Poles; the Polish language was to be the official one, and municipal institutions were granted to Warsaw and the chief cities. The people, however, received these overtures sullenly, and on the night of January 15, 1863, a secret conscription was held, and those suspected of disaffection to the government were seized in their beds to be enlisted. Attempts were made to assassinate the grand-duke and other Russian officials, and Lithuania and Volhynia were also declared in a state of siege. The committee of the National government issued its first proclamation in February 1863; and a week afterwards Microsslawski raised the standard of insurrection in the north-east, on the frontier of Posen. The committee (*Rząd*) had secret sessions, and was for a long time able to defy the Russian government. Its emissaries, called *szlachetki*, put to death many obnoxious persons and Russian spies. It also issued proclamations from time to time; and many districts of Augustowo, Radom, Lublin, Volhynia, and Lithuania were speedily in insurrection. It was a mere guerilla war, and no great or decisive conflicts took place; but the sympathy of Europe was largely enlisted on behalf of the Poles. Incendiarism and murder were rampant; and at last, with the assistance of Prussia and the secret support of Austria, the tsar's troops succeeded in trampling out (1864) the last embers of insurrection. Langiewicz, one of the leaders who had directed the struggle, held out for some time, but at length made his escape into Galicia. From the time of the suppression of the insurrection the kingdom of Poland disappeared from all official documents. All education in the university and the schools was thereafter carried on in Russian. The administration was at first given to eight military governors, and then to a commission sitting in St Petersburg. Finally, in 1868, the Polish province was absolutely incorporated with Russia, and the ten governments into which it was divided were grouped with the governments of Russia proper.

When the Great War of 1914-19 broke out Austrian Poland alone had autonomy, and the Poles of Galicia were allowed an influence out of proportion to their numbers in the eastern half of that land, where Ruthenians (Ukrainians) were more numerous. The Russian Grand-duke Nicholas, invading Galicia, promised autonomy and religious and linguistic freedom to a Poland united under the tsar. Germany and Austria invaded Russian Poland in their turn, and they likewise proclaimed a modified restoration of the Polish kingdom. The complete independence of Poland was established by the treaties of 1919 (see PILSUDSKI), with provision for the protection of racial, linguistic, and religious minorities. Boundary settlement was difficult. The

Ermeland and Masurian regions declared by overwhelming majorities to remain German. In Upper Silesia the German majority was smaller, and an unsatisfactory compromise assigned part of the province to Poland. Teschen-Silesia was disputed by Czechoslovakia, and was divided. Danzig the Poles would have liked as an outlet to the sea, but its new status as a free city was maintained. In the east Poland pushed her claims by force. When peace was made with Russia in 1921 a large slice of country in which Poles were a minority was added to the republic. Ukrainian claims to Eastern Galicia were set aside. In 1920 General Zeligowski seized Vilna. By a *coup d'état* Marshal Pilsudski overthrew the government in 1926, but declined the presidency.

Among histories may be recommended *Histoire de Pologne*, by Leliewel (Paris, 1844); *Geschichte Polens*, by Roppel and Caro (Gotha, 1840-88); *Przegląd Polskiej w Zarysach*, by Bobrzyński; *Outlines of Polish History* (1925) by Dybowski. See also books on Poland by Count Moitke (trans. 1885), Morfill (1893), Georg Brandes (trans. 1903), Alison Phillips (1915), and A. B. Roswell (1919); and *Poland*, ed. Piltz (1919). For maps of Poland at various dates, see, besides that given above, those at ERMENE.

POLISH LANGUAGE AND LITERATURE.—The Polish language is one of the most widely-spread members of the Slavonic family; it forms the western branch together with Czech or Bohemian, Slovak, and Sorbish or Lusatian Wendish. Kashubish and Masurian are so close akin that many count them dialects of Polish. Like all the Slavonic languages, it is highly inflected, having seven cases, and, by means of the so-called 'aspects,' expressing very delicate distinctions of meaning in the verb. Like Russian, however, it lacks the imperfect and aorist which are found in Bulgarian and Serbian. It has a rich vocabulary and great power of compounding words. It resembles Old Slavonic in having two nasals, like the French *n* and *m*; these are found nowhere else among Slavs except in a Bulgarian dialect. After the introduction of Christianity Latin exercised a great influence on its vocabulary and literature, and subsequent to the 14th century it adopted into its vocabulary numerous German words. Already in the 16th century Polish was a highly cultivated language, and began to supplant Latin, until then the language of the state and of the learned.

The history of Polish literature is divisible into six distinct periods. (1) From the earliest times to the middle of the 16th century, the epoch of the Reformation. The Poles, unlike most of their Slavonic kindred, are poor in legendary and popular poetry, and much of their early literature is in Latin. Casimir III. (q.v.), surnamed 'the Great,' did more than any other early Polish monarch for the encouragement of literature, and among other things founded the university of Cracow, which has continued to be the centre of intellectual life and culture in Poland. Among the very oldest literary monuments is a hymn to the Virgin Mary, ascribed to St Adalbert. The MS. in which it is preserved is dated 1408. Belonging to the middle of the 14th century is the so-called psalter of Queen Margaret, discovered at the convent of St Florian in 1826; there is also the Bible of Queen Sophia, which has come down in an imperfect copy, and is said to have been written about 1455. Writers of Latin chronicles were Martin Gallus, who flourished between 1110 and 1135, Kadłbek (1160-1223), and Jan Długosz or Longinus (1415-80), all of whom were ecclesiastics. The last is also worthy of remembrance as an able diplomatist. Jan Łaski, Archbishop of Gnesen (1457-1531), published a valuable collection of the oldest Polish laws, *Commune Ineolgi Poloniam Regni Privilegium*. In 1474 the first printing-press was established at Cracow by Gunther Zainer; the

first book in the Polish language was published there in 1521. In 1543 died the great astronomer Nicholas Copernicus. Some other specimens of Old Polish before the 16th century will be found collected in the valuable work of Nehring, *Altpolnische Sprachdenkmäler* (Berlin, 1887).

(2) The second period of Polish literature embraces that which is called the golden age (1548-1606). The series of poets begins with Nicholas Rej (1505-69), commonly called the 'father of Polish poetry', who spent his life at the courts of the Sigismunds. He was a Protestant. His best work is *Zwierciadło albo żywot Poczciwego Człowieka* ('The Mirror: or the Life of an Honourable Man,' 1567); he also wrote a play on the subject of Joseph. Although his language is rough and careless, there is much shrewdness and satire in his writings. Jan Kochanowski (1530-84), called the prince of Polish poets, has left a great deal of verse, the most beautiful of which are his *Treny* or Lamentations on the death of his daughter Ursula. His nephew Peter translated the *Jerusalem Delivered* of Tasso. Szarzyński (died 1581) introduced the sonnet into Polish. Szymonowicz (1557-1629) was a writer of good pastorals (*Nielutki*), as was also Zimorowicz (died 1629), a native of Lemberg. Sebastian Klunowicz, called Aernus (died 1602), is celebrated as a satirist and descriptive poet. The Reformation made rapid progress in Poland; many of the nobility were Calvinists, and the Sochmi came to reside in the country. Translations of the Bible appeared, but the Jesuit reaction soon made itself felt, especially under the influence of Skarga (1552-1612), renowned for his pulpit eloquence. Among the historians of this period the most celebrated are Martin Bielski, whose Chronicle was continued by his son Joachim; Lukas Górnicki (died 1591), author of a history of the Polish crown (*Dzieje o Koronie Polskiej*, Crac, 1637); Stykiowski (died 1582), whose Chronicle of Lithuania (Königs, 1582) is an admirable work; and Paprocki (died 1614).

(3) The third period of Polish literature, also called the Macaronic (1606-1764), is coincident with the rule of the Jesuits, who first obtained a footing in Poland about 1566, through the influence of Cardinal Hosius, soon got possession of the schools, and seriously checked the intellectual development of the nation. The literature of the period is for the most part poor, consisting mainly of bombastic panegyric; the language being corrupted by Latinisms and frequently by the introduction of whole Latin sentences—hence the term Macaronic. To this period belong Casimir Sarbievski, known by his Latin name Sarbievius (1595-1640), a celebrated writer of Latin odes; Wacław Potocki, now known to have been the author of the poem *Wojna Chocimska*, or War of Chocim, long preserved in manuscript; Kochowski (died 1699), a soldier-poet, who has left some sprightly odes; Twardowski (died 1660), a very prolific writer, author of a poem on Ladislaus IV.; Opaliński (1609-1656), who has left some bitter satires reviling his countrymen, whom he betrayed to the Swedes; Chroscinski, the translator of Lucan; Morsztyn, the translator of Corneille; and Elizabeth Druzbicka (died 1760), whose writings show some feeling for nature. History again took a Latin form, in spite of its having been written in the golden age in Polish; we may mention Starowolski (died 1656), author of *Polonia, sive Status Regni Poloniae Descriptio* (Wolfenbüttel, 1656), and other works; Kojałowicz, a Jesuit (died 1677), who wrote a History of Lithuania; and Kaspar Niesiecki, a Jesuit (died 1744), whose *Korona Polska* (4 vols. Lemberg, 1728-43) is the most important work on Polish heraldry.

(4) The fourth period is that of the reign of Stanislaus Poniatowski and the dismemberment of Poland, till the rise of romanticism (1764-1822); it owes its characteristics partly to the influence of French culture, partly also to the patronage of literature and science by King Stanislaus, the princes Czartoryski, Jabłonowski, and other noblemen, and the educational reforms of Stanislaus Konarski (1700-73). The good work begun by Konarski was carried on by Kopezyński (1735-1817), who was the first to establish on a scientific basis the grammar of the Polish language in his *Grammatyka Narodowa*; other authors were Bohonolec and Zablocki, who adapted a great many French pieces for the stage. But the best writer for the stage was Fredro, who belongs to a later period. The most noted dramatist, however, of this time, who may perhaps be called the real founder of the Polish stage, was Bogusławski (1759-1829), who wrote above eighty plays, the majority of which, under the title of *Dzieła Dramatyczne*, were published at Warsaw (9 vols. 1820). The most conspicuous poet of this time was Ignacy Krasiecki (1735-1801), who tried all kinds of literature—an epic on the war of Chocim, a weak production, and some satires and fables. We must also mention Trembecki; Cajetan Wegierski, the satirist; Godebski, and Wezyk. Adam Naruszewicz was but a mediocre poet, but he wrote a valuable *Historia Narodu Polskiego* ('History of the Polish People'), which he carried down to the year 1386. In 1801 the historian Tadeusz Czaicki, Franciszek Dmochowski, and Bishop Jan Albertandy founded at Warsaw the 'Society of the Friends of Knowledge,' which especially under the auspices of Staszyc bore good fruit till it was dissolved in 1832, when its library of 50,000 volumes was carried off to St Petersburg. At the same time Józef Osoliński, Hugo Kolłatag, and Stanislaus Potocki by word and writing exercised a great influence on the renovation of the national spirit. Karpiński (1745-1825) was a very popular poet as a writer of sentimental elegies and idylls, and Woroniez (1757-1829) was celebrated both as a poet and divine. Niemcewicz (1757-1841) was a statesman and soldier, and is remembered for his historical songs (*Spiewy Historyczne*). Lastly, as the great precursor of the romantic school, must be mentioned Kasimir Brodzinski (1791-1835), whose idyll *Wiosna* has been much admired.

(5) The fifth period runs from 1822 to about 1863: the era of romanticism, dating from the appearance of Mickiewicz, the greatest Polish poet. At Wilno, which after 1815 became the centre of Polish literary activity, several young men united, with Adam Mickiewicz (1798-1855) at their head, in a crusade against the still dominant French school of literature. After a short stay in Russia, Mickiewicz emigrated and spent the latter part of his life at Paris. He died at Constantinople, whither he had gone on a political mission at the time of the Crimean war. We have only space to mention some of his chief works, his *Ballads*, *Sonnets*, *Konrad Wallenrod*, and *Pan Tadeusz*, the last probably the most popular poem in the Polish language. Anton Malczewski (1792-1826), remembered by his *Maria*, a pathetic story of the Ukraine, was a prominent poet of what has been called the Ukraine school; Goszczyński (1806-76) was author of the narrative poem *Zamek Krasiński*; Bohdan Zaleski, author of *Duch od Stępy*, others are Odyniec, the friend of Mickiewicz, Siemieniński, Garezynski, Gaszynski. The two names most worthy to be placed by the side of that of Mickiewicz are those of Zygmunt Krasiński (1812-59), author of the strange poem *Nieboska Komedia* (the 'Undivine Comedy'), and Juliusz Słowacki (1809-49). Most of these men belonged to what

was called the 'Polish Emigration,' whose headquarters were at Paris. Kamil Cyprian Norwid (1821-83) has a posthumous reputation. Of the novelists of this period we have only space to mention the prolific Józef Ignacy Krasiński (1812-87). A very original writer for the stage is Count Alexander Fredro (1793-1876). He is thoroughly national: although French influence is visible in his pieces, the characters are Polish. Many distinguished historical writers belong to this period, of whom we may mention Joachim Lelewel (1786-1862), the author of many works of the greatest value, Szulski, Schmitt, Szajnocha, and Michael Bobrzyński, professor in the university of Cracow. By these men the history of Poland has been treated in all its details with great vigour.

(6) After romance comes the period of the realistic and historical novel and of 'modernism.' Poland's best-known novelist, Henryk Sienkiewicz (1846-1916), by no means stands alone. Bolesław Prus is the name under which Aleksander Głowacki (1847-1912) published his studies of social change. Gomułcki, Tetmajer, Żeromski, may be named; and Władysław Stanisław Reymont (1868-1925) is famous beyond his own country. Dramatists of this period are Stanisław Przybyszewski (b. 1868), Lucjan Rydel (b. 1870), and Tetmajer. The two latter are likewise poets, not so well known as the very popular Adam Asnyk (1838-97), Marya Konopnicka (1846-1912), or Jan Kasprzycz (1860-1926), considered the greatest of his time, or Leopold Staff (b. 1878).

The history of Polish literature has been written by Bontkowski and Wyszewski. See also Nitschmann's *Geschichte der Polnischen Literatur* (1884); Morfill's *Early Slavic Literature* (1883) and *Poland* (1893); Nevill Forbes's *Polish Literature* (1911); and Dybowski's *Periods of Polish Literary History* (1924).

Polar Bear. See BEAR.

Polar Circle. See ARCTIC.

Polar Exploration. In scientific geography some of the best work done since the beginning of the 19th century is due to explorations and discoveries in the Arctic and Antarctic regions. Not only have new lands been surveyed, but large and important accessions have been made to several branches of natural science. The original motive, however, in England at least, for exploring the Arctic seacoasts was to discover a route to the wealthy countries of eastern Asia, and to share in the traffic monopolised by Spain and Portugal when at the height of their power. Thus arose a double series of attempts, either to coast eastward along the north of Europe and Asia, or to sail westward across the Atlantic; the latter being afterwards modified into attempts to coast westward along the north of America. Hence arose the terms 'North-east Passage' and 'North-west Passage.'

Some have traced the history of Arctic exploration to the time of King Alfred, who, in his translation of Orosius (q.v.), inserted an account of the voyages of Ohthere and Wulfstan, narrated to him by Ohthere himself, who seems to have sailed round the North Cape to Lapland. The voyages of the Norsemen to Greenland (q.v.) and the opposite coasts of America in the 10th and following centuries may be regarded as to some extent coming within early Arctic attempts. Cabot's discovery in 1497 of Newfoundland and Labrador might, however, be termed the first step in the exploration of American polar regions—for the earlier expeditions claimed on behalf of Portugal must be regarded as doubtful. Three years after Cabot, Gaspar Corteereal and his brother made three separate voyages in the same direction, sailing northwards by Labrador, where they were stopped in 60° N. lat. The expedition commanded in 1535 by Sir Hugh Willoughby led the way to the North-east Passage. Willoughby

sighted Novaya Zemlya, but he and his men ultimately perished on the coast of Lapland. Chancellor, who accompanied him, landed in Russia near Archangel. Other Englishmen followed, Burroughs (1556), Pet and Jackman (1580), Henry Hudson (1608-9), Wood (1676), but none succeeded in getting much beyond Novaya Zemlya, though they did good work in exploring the north coast of Europe, Spitsbergen, and other islands in these seas. In 1594-97 Barentz, a Dutchman, led three expeditions, wintering on the north-east coast of Novaya Zemlya, 1596-97, after discovering Spitsbergen. After the failures of Hudson and Wood in the 17th century, the attempt to sail eastwards came to be considered quite hopeless. In 1607 Hudson succeeded in reaching 81° 30' N. in the neighbourhood of Spitsbergen.

Meanwhile some exploration of the Arctic parts of America had been going on. Frobisher first sailed in 1576, and in 1585-88 the great navigator Davis sailed up the strait bearing his name to 72° 41' N. and coasted the west of Greenland, 'the land of desolation.' Hudson, who had tried the North-east Passage, discovered in 1610 the strait and great bay which bear his name. From the size of the latter he concluded it to be part of the Pacific; but that was disproved by Banton, the next English explorer (1612). In 1615-16 Baffin, who went out at first under Bylot, and had had some scientific training, proved himself as skilful a navigator as Davis. He found the great northern outlet to Baffin Bay, and recorded some important magnetic observations. After the expedition of Fox and James in 1631, which only led to the partial exploration of what then was named Fox Channel, the North American coast was neglected for more than a century.

Russia was naturally interested in the exploration of the Siberian coast. Behring sailed from Okhotsk, and explored the straits which bear his name. In a second voyage (1741) he sailed from Petropavlovsk and explored part of north-west America. Another Russian expedition in 1742 found (but did not succeed in rounding) the most northerly point of Siberia, named from the discoverer Chelyuskin (or Severo); and an earlier one sailed from the Yenisei to 75° 15' N. In 1765 Tchitsakoff sailed to Spitsbergen, and finally reached 80° N. The New Siberian Islands were explored by Lichow (1770), Hedenström (1809-11), Anjou (1823), and Bunge and Toll (1884-87). Wrangel explored the Siberian coast between Cape Chelagaskoi and the Kolyma in 1820-23, and in 1843 Middendorf laid down the unvisited coast in the neighbourhood of Cape Chelyuskin. In the reign of George III. there was a new revival of English zeal in naval adventure. Captain Phipps (afterwards Lord Mulgrave) sailed in June 1773 to Spitsbergen, and finally reached 80° 48' N. Cook, who next made the attempt through Behring Strait, could only penetrate to 70° 45'. After those failures there was no effort made till 1806, when Scoresby reached 81½° N. immediately north of Spitsbergen. In following expeditions Scoresby explored Jan Mayen Island and the east coast of Greenland, largely adding to our knowledge of the physical geography and natural history of the Arctic regions. The expeditions of Buchan and Franklin in 1818, of Clavering in 1823, of Graah in 1828, of De Blotseville in 1833, did not reach higher latitudes than those which preceded them.

To encourage polar exploration on the North American coast the British government had promised a reward of £20,000; yet nothing was done till the Admiralty in 1818 sent out Ross and Parry, who only explored part of Lancaster Sound. Next year Parry alone discovered Prince Regent Inlet, Barrow Strait, and (110° W.) Melville Sound. Following up this line of exploration, Ross in 1829

at last reached a point only 200 miles from Turnagain Point, which had recently been found by another expedition sailing eastward from Behring Strait. Ross then named Boothia Felix, in which the magnetic pole lay, and King William Island. In 1826-27 Franklin traced the North American coast from the Mackenzie River westwards to Cape Beechey, 860 miles, while his companions, Richardson and Kendall, proceeded eastwards towards the Coppermine River. Dease and Simpson in 1833 extended the survey of the American coast for about 100 miles, from Point Turnagain. In 1846-47 Dr John Rae explored the west shore of Boothia Gulf, and discovered Boothia Felix to be a peninsula. In 1851 he surveyed the coast from the Mackenzie River to King William Island, and also the south-east coast of Victoria Island.

The success of Ross led to Sir John Franklin's expedition (left England 19th May 1845), so unfortunate to him and his crew, so famous from the number of search-parties which it occasioned. His object was to penetrate to Behring Strait from Lancaster Sound (see FRANKLIN, SIR JOHN). In 70° N. lat., 98° 30' W. long., on the west side of King William Island, the ships were beset, and Franklin died June 1847. The survivors abandoned the ships, and all perished. Many search-expeditions were sent out. One of these, under Collinson and McClure, sailed to Behring Strait in 1850. Fixed in the ice on its eastward voyage, McClure's crew was rescued next spring by Sir Edward Belcher, about 60 miles west of Barrow Strait. Belcher now returned towards the Atlantic, and thus McClure with his crew reached England in 1854 after actually traversing the North-west Passage from ocean to ocean. He therefore received the honour of knighthood, and a sum of £10,000 was voted by parliament to him and the crew. Dr John Rae in 1854 first learnt from Eskimo of the fate of Franklin and his men, and received the government reward for the discovery. He was followed by Captain (afterwards Sir) L. McClintock, sent out by Lady Franklin in 1857 in the *Fox*. McClintock obtained many relics from the Eskimo of Boothia, and in a cairn on Point Victory found the record which told the story of the expedition. Owing to the different Franklin expeditions from Britain and the United States the whole Arctic coast of North America was explored almost exhaustively, so that several routes are now completely mapped between Davis and Behring Straits; and in 1904-6 Amundsen in the *Gjøa* successfully made the passage, after devoting two years to the investigation of the North Magnetic Pole area. For commercial purposes, however, the North-west Passage is of no value whatever.

Seeking the North-east Passage, Parry, sailing in 1827 to Spitzbergen, reached 82° 40' N. After 1855 Sweden began exploration in this region under the active guidance of Professor (afterwards Baron) Nordenskiöld, who in 1858-72 did much exploring work in the Spitzbergen islands and seas. In two voyages he reached the Gulf of Obi. At last, in 1878, he rounded Cape Chelyuskin, 77° 42' N., and after wintering near Behring Strait sailed into the Pacific and reached Yokohama in September 1879. Before that date an Austrian expedition under Lieutenants Payer and Weyprecht had been singularly successful, having discovered an island about 200 miles north of Novaya Zemlya. This new group, Franz-Josef Land, extends from 80° N. to about 82°. At a later date (1880-82) this land was still further explored to the north-west by Mr Leigh Smith. In 1894-97 the Jackson-Harmsworth expedition, under Mr F. G. Jackson, explored the southern section of the archipelago, and was able to render help to Nansen on his return from his famous journey to the North.

The more recent exploration to the north of America has added somewhat to our geographical knowledge, in addition to the attainment of the North Pole, and is of interest in certain scientific aspects. The expedition of Kane and Hayes in 1853-55 reached in sledges Cape Constitution in 80° 27' N., and saw what appeared to be an open polar sea. Hayes again (1860-61) reached 81° 35' N. In 1871 the *Polaris*, under Captain C. F. Hall, sailed from New London, U.S., and reached the latitude 82° 16', which was surpassed in 1876 by the British expedition under Captain Nares; Captain A. H. Markham, by means of sledges, reaching 83° 20' N. At the same time Aldrich explored the north shore of Grinnell Land. Full of interest but disastrous was the 'Lady Franklin Bay Expedition,' 1881-84, conducted by A. W. Greely. The explorers were compelled to abandon their ships and find their way southwards through almost impassable ice. In October 1883 Greely and his brave companions landed at Cape Sabine, one of the bleakest spots in the Arctic; and there in June 1884 Commander Schley found the six men who still survived. In the early part of Greely's exploration, when in Grinnell Land, one of his party, Lieutenant Lockwood, succeeded in reaching 83° 24' N. lat., on the coast of Greenland. The Greely expedition also explored the interior and the west coast of Grinnell Land. In 1869-70 Captain Goldewey's expedition reached 77° N. on the east coast of Greenland. The *Jeanette* expedition, under Commander De Long, sent out by the *New York Herald* in 1879 to push north by Behring Strait, ended in disaster. The vessel was crushed in the ice in June 1881 in 77° N., 155° E., and De Long and many of his men perished. Lieutenant Terry, sent out to search for the *Jeanette*, explored Wrangel Island. The icy plateau which covers Greenland (q.v.) was in 1888 crossed by Nansen, and Peary did good work there in 1886-90, rounding the northern end of Greenland and reaching 84° 17' N. lat. In 1893-96 Nansen in the *Fram* sailed along the north coast of Europe and Asia to the New Siberian Islands, where the *Fram* entered the great north-west current. About 84° N. lat. Nansen with Johansen left the ship in March 1895, and in three weeks reached 86° 13' on the ice afloat. In 1900 a party under Captain J. Cagni reached lat. 86° 34'. In 1905-6 Peary reached 87° 6' N. lat., and on 6th April 1909 reached the Pole by a sledge-journey over sea-ice from the north coast of Grant Land.

In 1899-1902 an expedition in the *Fram* under Captain O. Sverdrup carried out extensive explorations on the western coasts and straits of Grant Land, adding Axel Heiberg Land and several other large islands to the American Arctic archipelago. From 1913 to 1918 V. Stefansson explored the north-west part of that archipelago, and added several new islands.

In 1905-7 Mylus Erichsen for the first time accurately delineated the north-east coast of Greenland, he and his companions perishing before the relief expedition under Einar Mikkelsen in 1909-11 could reach them. Their splendid records and observations were recovered. From 12 onwards Russian expeditions have carried out valuable hydrographic work from Behring Strait westward, discovering in 1913 new land north of Cape Chelyuskin, stretching some 200 miles up to 81° N. and 96° E. It was named Nicholas Land.

The Arctic coasts of Asia have been completely resurveyed in recent years.

In 1912 de Quervain and in 1913 J. P. de Koch made new crossings of the inland ice of Greenland, and in recent years the Danes, notably L. Koch and K. Rasmussen, have been very active in the

exploration of northern Greenland. In 1916-17 D. Macmillan made surveys in Ellesmere Land. From 1922 to 1925 O. Wisting drifted in the *Maud*, hoping to repeat the *Fram's* adventure on a more northerly course, but was forced to return to Alaska. After an unsuccessful attempt in 1925 to fly from Spitsbergen to the Pole, R. Amundsen tried again in 1926, using a semi-rigid Italian airship in place of a hydroplane. He left Spitsbergen on 11th May, passed the Pole, and descended safely in Alaska after a flight of 72 hours. Two days earlier the American, R. E. Byrd, made an aeroplane flight from Spitsbergen, returning in 15½ hours. He claimed to have flown over the Pole.

An international series of polar observatories was established around the north polar area, and two in the south, for the purpose of taking a complete year's observations, beginning with August 1882. The result was a series of observations of high value on the physics, meteorology, and natural history of the polar, especially the Arctic regions.

In the Antarctic Cook was the first to undertake a systematic exploration of the region, sailing all round at a high latitude, and reaching 71° 10' S. in 106° 54' W. In 1820 E. Bransfield, in sighting Trinity Land, first saw the Antarctic continent. In 1821 the Russian Bellingshausen discovered the islands named Alexander Land and Peter Land. Weddell in 1823 sailed south to 74° 15', and in 1831 Biscoe discovered Enderby Land, 66° 25' S., and Graham Land. The French expedition, 1838, under D'Urville, found its advance in the Weddell Sea blocked by ice extending east and west for 300 miles, but farther east found Addie Land. In 1840 the United States expedition under Captain C. Wilkes discovered a long coast-line, apparently extending from Enderby Land eastwards to Ringold's Knoll, but the only part of this which has since been found was discovered by Balleny in 1839. The most important results obtained in the Antarctic region in the 19th century were due to Sir James Clark Ross, who made three voyages in 1839-43, discovering Victoria Land, with a lofty range containing the volcanoes Erebus and Terror, and also the Ice Barrier. He traced the coast from 71° S. to 78° 11' S., the highest latitude till then reached in the Antarctic. The *Challenger* expedition in 1874 only just crossed the Antarctic Circle.

In 1895 C. E. Borchgrevink from a whaler was the first to land on the southern continent, near Cape Adare. In 1898 he led an expedition in the *Southern Cross*, which wintered in the Antarctic, and sailed along the Ice Barrier, reaching 78° 50' S. on the Barrier surface. In the same year a Belgian expedition in the *Belgica* explored the north and west coasts of Graham Land, and drifted for about a year in the ice; while a German expedition in the *Falldin* rediscovered Bouvet Island. In 1901 a well-equipped expedition, organised by the Royal and Royal Geographical Societies, under Captain R. F. Scott, voyaged along the Ice Barrier to King Edward Land. It wintered on shore near Mounts Erebus and Terror, which are on an island. Scott with Wilson and Shackleton pushed southward across the barrier to 82° 17' S. lat., while other parties traversed the barrier in various directions and explored the mountains to the west. At the same time a German expedition under E. von Drygalski, in about 90° W. and 65° S., discovered Kaiser Wilhelm Land. In 1903-4 W. S. Bruce in the *Scotia* explored an entirely unknown sea lying between the tracks of Weddell and Ross, reaching 74° 1' S. A mountainous land was sighted to which the name of Coats Land was given. About the same time O. Nordenskjöld did good work in the neighbourhood of Graham Land. In 1904-5 J. B. Charcot cruised along west Graham Land and found a new coast which he named

Loubet Land. In 1908-10 he led a second expedition, which made its way some distance beyond Loubet Land, adding considerably to our knowledge of the coast and islands. In 1907 E. H. Shackleton led an expedition to McMurdo Sound. Mount Erebus was ascended, and the South Magnetic Pole reached. Marching over the barrier and plateau, Shackleton reached 88° 23' S., 162° E. In 1910 Scott led a second expedition, which landed in McMurdo Sound. Parties of the scientific staff were landed at various points of the coast. Scott himself, with Wilson, Oates, Bowers, and Evans, pushed his way along Shackleton's route and reached the Pole in January 1912, only to find that he had been forestalled by Amundsen. Unfortunately, owing to adverse conditions, all five perished on the return journey. The work of the expedition as a whole was a brilliant success. R. Amundsen established the headquarters of his admirably equipped expedition in 1911 in an opening in the Ice Barrier about 400 miles east of Scott's position. Following 164° W. longitude he struck the mountain range of Victoria Land in about 85° S. He reached the highest point of the plateau near the 88th parallel, and reached the Pole at a height of 10,500 feet on 16th December 1911, returning to his base in January 1912.

In 1912 W. Filchner found Luitpold Land, a continuation of Coats Land and the Weddell Barrier, and in 1911-14 D. Mawson mapped the coast from 150° E. to Wilhelm Land.

Sir Ernest Shackleton in the *Endurance* in 1914 led an expedition to the Weddell Sea. His plan was to land parties on that coast to carry on scientific work, while he with other members of the staff pushed their way across the Pole. An auxiliary expedition was sent to the Ross Sea for the purpose of planting depots of provisions as far south as possible with this end in view. Unfortunately disaster met the expedition in the treacherous Weddell Sea. The ship foundered, and it was only by the indomitable exertions of the leader that the whole party did not perish. They were landed safely in South America in May 1916. Caird Coast was added to the extent of Coats Land.

The result of all these expeditions has been to add a vast amount to our knowledge of Antarctica and the Southern Ocean. Much of its outline has been mapped; a great knowledge of the character of the interior has been obtained; great gains have been made in geology, biology, meteorology, magnetism, oceanography, and other sciences. Still, though an exhaustive survey of the continent is not required, it is desirable to have the survey of the coast completed and a general knowledge of the interior, and there is ample room for further exploration in the interests of science.

The physical geography of the north and south polar regions is largely treated at ARCTIC OCEAN, ANTARCTIC OCEAN. See also GEOGRAPHY, GEOGRAPHICAL DISTRIBUTION, ANTARCTICA, GREENLAND, SPITSBERGEN, NOVIA-ZEMLYA, FRANZ-JOSEF LAND, SIBERIA, NEW SIBERIAN ISLANDS, GLACIER, ICE, and the articles on Hudson, Cook, Franklin, Ross, Parry, McClure, Hall, Nordenskjöld, Greely, Nansen, Peary, Scott, Shackleton, Drygalski, and other polar explorers; Nansen's *In Northern Mists*, Barrow's *History of Voyages to the Arctic Regions* (2 vols. 1818 and 1846); C. Greely's *Handbook of Polar Discoveries*; *Journal, Proceedings, and Geographical Journal, Roy. Geo. Soc.*; *Scottish Geographical Magazine*; and the published narratives of the various Arctic and Antarctic explorations.

Polarisation. (1) *Of Light.*—An ordinary narrow beam of sunlight has no sides, and is always divided into two equal beams by a crystal of Iceland spar; but if it has once been reflected from glass or water, it will then be found in general that

different results, as regards the intensities of these two beams, are produced by turning the crystal of Iceland spar round the axis of the beam into different successive positions. The beam is no longer the same all round, but has acquired sides. On the vibratory or undulatory theory of Light (q.v.) this shows that the vibrations must be transverse to the direction of propagation (see POLARITY). Suppose a long cord, fixed to a distant wall, to be held in the hand; apply a sharp up-and-down movement; an up-and-down wave will run along the cord to the wall; this illustrates the mode of vibration in a beam of *plane polarised* light. Make the hand move in a circle, in a direction contrary to that of the hands of a clock; a wave will run along in the form of a screw; this screw will have the form, and will advance after the fashion, of a corkscrew; this illustrates the mode of vibration in a *right-handed circularly polarised* beam of light. Make the hand move in a circle clockwise; the wave-screw advances in a left-handed fashion; this illustrates *left-handed circularly polarised* light. Make the hand move in an ellipse; an elliptical disturbance travels, screw-fashion, right- or left-handed as the case may be; this represents *elliptically polarised* light. Communicate a series of disturbances of the greatest irregularity in which no one direction, up or down, right or left, has on the whole any predominance; the irregular succession of transverse disturbances which will travel along the cord will represent the vibration in a beam of *common or natural* light. Assume that while communicating these irregular disturbances the hand is hampered but not disabled with reference to any particular direction, say up and down; the vibrations in that direction are on the whole less than those from right to left; and the whole complex of irregular disturbances would, if they wrote their own path, tend to fill up an ellipse with their trace-marking rather than to fill up a circle, as the vibrations in common light would tend to do; this would represent the nature of the vibrations in *partially polarised* light. Now suppose a slot in a board, which will allow the cord to swing from end to end of the slot, but will not allow the cord to swing athwart the slot; all those oscillations or components of oscillation which are parallel to the slot will be able to traverse the slot; but those which are at right angles to these will not be allowed to pass. On endeavouring to transmit through the slot the complex of oscillations which illustrate the vibrations of common or natural light, it will be found that no motion at right angles to the slot is transmitted, and that what does pass through is a complex of irregular oscillations restricted to the plane of the slot. A second slot, at right angles to the first, will cut off the whole of what passes through the first; and the propagation of transverse oscillations along a cord may thus be entirely checked. If, however, the second slot be parallel to the first, all the oscillations transmitted by the first may pass through it also; and if it lie in an intermediate direction, the second slot will allow a proportion to pass, which depends upon the angle between the two slots, being proportional to $\cos \theta$, where θ is that angle. The first slot illustrates the functions of a polariser; the second illustrates those of a second polariser or analyser. A polariser reduces incident common light to a plane polarised condition, and an analyser at right angles to the polariser will quench it altogether.

The phenomena of polarised light were first observed in sunlight reflected from water or glass. Common or natural light so reflected is always, except when it retraces its path by direct reflection, more or less partially 'polarised by reflection.' The polarisation is more or less complete according

to the angle of incidence. At one particular angle of incidence the reflected light is as nearly plane polarised as the particular reflecting substance employed can make it. At this angle, the so-called 'angle of complete polarisation,' the reflected and the refracted rays are (or tend to be) at right angles to one another, and $\tan i = \mu$, where i is the angle between the incident ray and the normal, and μ is the index of refraction (see REFRACTION). Metal reflectors have no angle of complete, but only of maximum, polarisation; and even among such substances as glass, which are usually said to have an angle of complete polarisation by reflection, it is only those whose index of refraction = 1.46 which can completely polarise common light by a single reflection. In that case the intensity of the reflected plane polarised beam is to that of the original incident beam of common light as 6.52 to 100, or 6.52 per cent. The intensity of light polarised by one reflection is therefore a good deal less than the 50 per cent. which might be secured by any contrivance which effectually acted in a way analogous to the first slot above mentioned. The intensity of light polarised by reflection is greatly improved by using, instead of a single reflecting plate, a pile of plates. A crystal of tourmaline or of iodo-sulphate of quinine will, on the whole, allow only light polarised in one particular plane to pass through; but then it darkens it and colours it. Advantage is accordingly taken of the property of a doubly-refracting transparent crystal, such as Iceland spar, of dividing an incident beam of common light into two equal beams, which are, when they travel in principal sections of the crystal (see REFRACTION), polarised in planes at right angles to one another, and each of which possesses (absorption apart) half the intensity of the original beam. As these two beams diverge from one another it is comparatively easy to arrange that one of them shall remain parallel to the axis of the incident beam and of the apparatus, while the other is allowed to wander away laterally; and this is the basis of the construction of the prisms of Nicol, Poucault, Wollaston, Koehne, and others, which receive incident ordinary light and transmit plane polarised light.

Two beams of plane polarised light can *interfere* with one another (see INTERFERENCE) provided they originate in the same source, when their vibrations are wholly or partly in the same direction, but not if they be at right angles to one another; and a beam of light polarised in any way can give rise to the phenomena of *Diffraction* (q.v.).

On interposing in the path of a plane polarised beam of light an analyser, so placed as to allow none of that light to be transmitted, and then placing in the course of the plane polarised beam before it reaches the analyser a thin film of a doubly-refracting substance, such as mica, the field of view may become filled with light. The doubly-refracting film generally breaks the incident plane polarised beam into two plane polarised beams, which are, after emergence from the film, parallel to one another and on the whole coincident if of sufficient breadth. These two beams are differently retarded in the mica; and, according to the amount of this relative retardation and to the position of the principal plane of the interposed film, their resultant, that which reaches the analyser, may be a beam plane polarised in the original plane, plane polarised in another plane, elliptically polarised, or circularly polarised. In all these cases except the first, the analyser lets some light through. If we substitute for the analyser a doubly-refracting crystal, there will in general be two images seen on looking through; but as this crystal itself introduces relative retardations, the result of which depends on the wave-lengths—i.e. on the colours

—the different wave-lengths may give different relative intensities in the two images: some wave-lengths may predominate in the one image, the rest in the other; the two images may thus be coloured; and when coloured they will be complementarily coloured. The phenomena of colour produced by the reaction of polarised light upon various doubly-refracting crystals and films, &c.—all which colour-phenomena are due to varying relative retardations of ordinary and extraordinary rays in doubly-refracting media, and are either uniform all over the resultant wave-front or vary with respect to particular parts of it—are of great variety and extreme beauty. For an account of these we refer to Thomas Preston's *Theory of Light* (4th edition by Thrift, 1912).

A beam of plane polarised light may be recognised by means of a crystal of Iceland spar. Paste a piece of paper with a pinhole in it on one end of the crystal; look through, turning the crystal round; each of the two images waxes and wanes and disappears alternately with the other. In partially polarised ordinary light, and in elliptically polarised light, the two images wax and wane alternately with one another, but do not disappear. In circularly polarised and in ordinary light the two images remain equal to one another, and present no variation of intensity. Circularly or elliptically polarised light is converted by a plate of mica of proper thickness into plane polarised light; natural light, unpolarised or partially unpolarised, is not so affected by the same plate of mica. These criteria enable the character of a given beam of light to be readily recognised.

The name of Rotatory Polarisation is given to the phenomenon observed when a beam of plane polarised light is sent through a slice of quartz cut parallel to the axis. The plane of polarisation is found to have been rotated, and that into a different position for each component colour; so that, with white light incident, a crystal of Iceland spar gives two images complementarily coloured, and varying in colour on rotation of the prism. This property of rotation is shared by many substances even in solution: cane-sugar, grape-sugar, camphor act like quartz, rotating the plane of polarisation to the right (dextro-rotatory); fruit-sugar and starch rotate the plane to the left (laevo-rotatory). Upon this property are based various instruments for the quantitative estimation of saccharine solutions, called saccharimeters. If the light whose plane has been rotated be reflected back through the plane-rotating medium, the rotation is reversed, and the light emerges polarised in the original plane. A somewhat similar phenomenon, though much less pronounced, is observed on passing a beam of light through heavy glass in a strong magnetic field; but here, if the path of the light be reversed by reflection, the rotation of the plane is not reversed but doubled.

As to the direction of vibration in a plane polarised ray, a ray polarised by reflection is said to be polarised in the plane of incidence—i.e. in a plane containing both incident and reflected rays: the question is whether the vibration is in this plane or at right angles to it. Fresnel worked out the consequences of the vibration being at right angles to this plane, and arrived (on the assumption that the density of the ether in two media, at whose bounding surface reflection takes place, is different in the two media, while its elasticity is the same in both) at consequences consistent with experiment. Neumann and MacCullagh, from a contrary hypothesis as to the elasticity and density of the ether, and on the hypothesis that the vibrations are parallel to the plane of polarisation, arrived at optical conclusions which, so far as it is possible to test them by experiment, are

equally consistent with observation. Clerk-Maxwell's electric or electro-magnetic theory of light, confirmed by Hertz's researches (see MAGNETISM), requires that there should be an undulatory propagation of electric disturbances at right angles to the plane of polarisation, and of magnetic disturbances parallel to that plane. See LIGHT.

Polarisation of light is useful in several ways. A polariser can be made to cut off the glare from the surface of water while we look into its depths; or to cut off a large portion of the light which is reflected from haze and obscures our view of landscape; or it may be used in examining the light of the sky, which is partly polarised, because due to reflection (see SKY). A polariser and analyser are of use in examining the strained condition of glass which, when heated or bent, &c., or too suddenly cooled, will give rise between crossed prisms to phenomena analogous to those produced by a doubly-refracting crystal; and they are also of use in low-power microscopic work for the examination or identification of crystals and of many organic structures. Crossed prisms have also been used to reduce the intensity of a beam of light to any required percentage for photometric purposes.

(2) *Polarisation of Dielectric*.—The condition of the dielectric or medium between two opposite charges of electricity: a condition of stress.

(3) *Polarisation of a Galvanic Cell*.—Production of a reverse 'electromotive force' by the deposition of elements of the electrolyte upon, or their combination with, the plates of the cell.

(4) *Polarisation of Electrodes*.—An entirely similar phenomenon in an electrolytic cell. When the battery is taken off, a reverse current flows from the electrolytic cell; this is the basis of the gas battery and of the modern accumulator (see ELECTRICITY).

Polarity, in physical science, a word of various application; but in all its uses there is present the idea of a directed quantity or Vector (q.v.). A sphere, situated in space, is a perfect type of all-sidedness, presenting the same aspect in every direction. Let this sphere, however, begin to rotate about some diameter, and at once it becomes a polar body; it becomes possessed of polarity (see POLES). Looked at from one end, it appears rotating clockwise; looked at from the other, it appears rotating counter-clockwise. A similar polarity is acquired by a body of any shape when it is set spinning about some axis. Hence we may take rotation as a very perfect illustration of kinematic polarity.

Perhaps the most familiar example in physics of a polar body is the magnet. Its polarity is a force-polarity, the ends or *poles* of one magnet having a selective action upon the ends or poles of another. This particular action is, however, only one of a host of manifestations of what is known as Magnetism (q.v.); and the general tendency in modern theory is to explain all magnetic phenomena as being essentially rotational. Thus, again, from a physical or dynamic point of view, we conceive of rotation as a true type of polarity. The phenomena of static electricity have also been discussed as analogous to certain phenomena in vortex motion. In electrolytic polarisation, however, it is difficult to see any rotational analogy. Here the electrodes which bring and carry away again the electric current flowing through the decomposing liquid acquire new properties and functions which have distinct directive relations to the current that produced them. See ELECTRICITY, INDUCTION, MAGNETISM.

In all the cases so far mentioned the polarity or polarisation involved is of such a nature as that originally typified by the sphere's rotation; there are two ends which in some respects have opposite characteristics. In polarisation of Light (q.v.),

however, this condition is no longer always fulfilled. For instance, a plane polarised ray of light which is stopped by a Nicol prism passes more or less completely as soon as the prism is rotated round an axis co-directional with the ray. The ray has, in fact, peculiarities as regards its sides—its 'polarity' is strictly speaking lateral, not polar. On the other hand, in a circularly polarised ray we have, according to the ordinary theory, a true kinematic polarity of a rotational kind, so that, looking along the ray, we are able to distinguish right-handed and left-handed circular polarisations. It may be mentioned as a final illustration that the rotation of the plane of polarisation by means of quartz or a saccharine solution is not a real polar phenomenon, the rotation being for any one substance always in the same sense relatively to the travelling ray; but that the rotation of the plane of polarisation in a magnetic field is a true polar phenomenon, changing sign with the direction of the field.

Polar Lights. See *AURORA BOREALIS*.

Polder, in the Netherlands, is land below the level of the sea or nearest river, which, originally a morass or lake, has been drained and brought under cultivation. An embankment, forming a canal of sufficient height to command a run towards the sea or river, is made, and when carried quite round, as in the case of the Haarlem Lake, it is called the *Ringvaart*. At one or more points on the embankment apparatus for lifting water is placed, and worked by wind or steam power. If the lake deepens towards the centre, several embankments and canals are necessary, the one within the other, formed at different levels as the water-surface becomes lessened, a connection being maintained with the outer canal, which secures a run for the drainage water. In the Scheemr polder in North Holland are four canal levels, the land between forming long parallelograms. The great polder of the Haarlem Lake (q.v.) is to be surpassed by that of the Zuidzee (q.v.). See also *HOLLAND*.

Pole. See *ROD*.

Pole, DE LA, a family descended from William de la Pole, a Hull merchant, whose son Michael in 1383 became chancellor under Richard II., in 1385 was made Earl of Suffolk, and in 1389 died an exile in France. His grandson William (1396-1450) was the year before his death raised from Earl to be Duke of Suffolk, having since 1445 been practically prime-minister. His administration was a disastrous one; and he was on his way to a five years' banishment in Flanders, when he was captured by a ship sent after him, and beheaded. John de la Pole, Duke of Suffolk (died 1491), married Elizabeth, sister to Edward IV. and Richard III.; and from this marriage sprang John, Earl of Lincoln (died 1487), Edmund, Earl of Suffolk (executed by Henry VIII., 1513), two churchmen, four daughters, and Richard, on whose death at the battle of Pavia in 1525 the line became extinct.

Pole, REGINALD, 'Cardinal of England,' was the son of Sir Richard Pole, and Margaret, Countess of Salisbury, the daughter of the Duke of Clarence and niece of Edward IV. He was born in Staffordshire, March 1500. He received the rudiments of his education from the Carthusians at West Sheen, and at twelve years of age he was sent to Magdalen College, Oxford. His relationship to the crown made him an important person, and being destined for the church, he was presented at an early age with several benefices. At nineteen he went to Italy with a pension from the king to finish his studies at Padua. He returned to England in 1527. He was then high in Henry's favour, while Queen Catharine was much attached to his mother. Pole's position, when the question of the king's divorce was raised, became a difficult one. He

appeared at first disposed to take the king's side. In 1530 we find him in Paris endeavouring to obtain from the university a decision on the divorce question, but becoming more and more disgusted with the policy of Cromwell, he refused the archbishopric of York which was offered to him on the death of Wolsey, and remonstrated with the king upon the course he was pursuing. Henry, however, made no open quarrel with him; and Pole left England in 1532, and after a short stay at Avignon took up his residence in Italy. Here he formed intimate friendships with a number of men of learning and piety—Sadoleto, Contarini, Morone, Flaminio, Priuli, and others—who were urgent for an internal reformation of the church, and whose views on justification by faith as a rule approximated closely to the doctrine of Luther. Pole still retained his English ecclesiastical revenues, and made no hostile demonstrations against Henry, but in 1535 he entered into a political correspondence with the Emperor Charles V. Pole was now compelled by Henry to declare himself, which he did in a violent letter addressed to the king, afterwards famous in its revised form as the treatise *De Unitate Ecclesiastica*. The king withdrew Pole's pension and preferments. Paul III., on the other hand, made him a cardinal (22d December 1536), and legate to England. Henry retainted by causing a bill of attainder to be passed against him, and by setting a price on his head. His mother, with other relatives, was thrown into the Tower on the ground of treasonable correspondence with the cardinal, and subsequently beheaded. Pole's diplomatic career was not, however, a brilliant one. His several attempts to procure the invasion of England were not successful. From 1541 to 1542 he acted as governor of the 'Patrimony of St Peter,' of which Viterbo was the capital. He took an active part in the discussions on the Interim, and when the Council of Trent was opened in 1545, he was one of the three cardinals who acted as legate-presidents. In the conclave which followed on the death of Paul III. in 1549, Pole was at one moment on the point of being elected pope; after the election of Del Monte, as Julius III., he lived in retirement at a Benedictine monastery at Mazzano on the lake of Garda, until the death of Edward VI., when he was at once commissioned to proceed to England as legate *a latere*, to assist Queen Mary in the reconciliation of the kingdom to the Church of Rome.

Pole was still only in deacon's orders, and had not abandoned the idea which he had apparently entertained from his youth, of marrying Mary Tudor. The queen for a moment considered the project of obtaining a dispensation for this union with favour, but the influence of Charles V. prevailed in favour of his son Philip. The emperor's fear of Pole's interference or precipitancy led to the legate being prohibited from entering England for more than a year. Philip was married 25th July 1554. Pole's attainder was removed by parliament, 22d November, and two days later he arrived in London. He was provided with ample powers to allow the owners of the confiscated church property to retain their possessions, a condition which was understood to be absolutely necessary to secure the submission of parliament. On the 30th Pole solemnly absolved the Houses of Parliament and country from their schism, and reconciled the Church of England to Rome. As long as Cranmer lived Pole would not accept the archbishopric of Canterbury, although the see was vacant by his degradation, but the day before Cranmer was burnt Pole was ordained priest, 20th March 1556, and on the 22d consecrated archbishop. In the meantime Giovanni Pietro Caraffa, once a friend of Pole and afterwards his bitter enemy, had become (May

1555) Pope Paul IV. The pope was indignant at the concessions made by the authority of his predecessor to the holders of church property; and he revived the accusations of heresy which had been in former days brought against Pole, both on the ground of his leniency towards Lutherans when papal governor at Viterbo, and of his well-known opinions on justification. Paul IV. was, moreover, now at war with Spain, and could not tolerate Pole as his ambassador at the court of Philip and Mary in England. The cardinal's legation was accordingly cancelled, and he was summoned before the Inquisition, into the prisons of which the pope had already thrown Pole's friend, the Cardinal Morone. Mary angrily protested, and the pope somewhat relented. He would not reinstate Pole, but appointed William Peto, a Franciscan friar, as cardinal and legate in his place. The queen gave orders that the papal messenger bearing the hat should be stopped at Calais, and Peto died without receiving it. When peace was made between the pope and Spain, Paul still refused to reinstate Pole as his legate, and he did not withdraw the odious and unjust accusation of heresy. When the queen died, 17th November 1558, Pole, whose health had been long feeble, was lying dangerously ill. The impending failure of all his hopes no doubt hastened his end. He died on the same day, twelve hours after the queen, in his fifty-eighth year.

It has been a disputed question how far Pole was responsible for Mary's persecution of Protestants. His leniency towards heretics in Italy had even brought him into trouble. Nevertheless it is remarkable that after Philip's departure from England and Gardiner's death (November 1555), when Pole became the queen's supreme adviser and her inseparable companion, the persecution increased in violence. If it was not instigated by Pole, it could not have continued without his sanction and support. In his diocese of Canterbury he issued in the last year of the reign a fresh commission against heretics, and in July he delivered over to the secular arm five persons, who were burnt alive at Canterbury a week before his death.

Besides the above-mentioned *De Unitate*, Pole was the author of *De Concilio* (Rome, 1562), *De summi Pontificis officio* (Louvain, 1560), and *De Justificatione* (Louvain, 1569). His letters, with a life prefixed, were published by (Jurini) Brescia, 1744). Recentelli's life of Pole, originally written in Italian, was published in a Latin translation at London in 1690, and in an English translation by B. Pyc in 1766. The first edition of Philipps' life, which occasioned much controversy, appeared in 1764-67. See *Lives* by Hook (in vol. viii. of his *Archbishops of Canterbury*), A. Zimmermann, S.J. (1893), and Martin Haile (1910); K. B. McFarlane's *Cardinal Pole* (1924).

Pole, William (1814-1900), born in Birmingham, was appointed Professor of Civil Engineering at University College, London, in 1859, and also acted as examiner in music. He produced much literary work and was a scientific exponent of whist.

Polecat, or **FITCHET** (*Mustela putorius*, or *Putorius fitchius*), a large relative of stoat and weasel. The body is about 17 inches in length, the tail 7 inches more. Its colour is a deep blackish-brown; the head, tail, and feet almost black, the under parts yellowish, the ears edged with white, and a whitish space round the muzzle. The hair is of two kinds—a short woolly fur, which is pale yellow, or somewhat tawny, and long shining hairs of a rich black or brownish-black colour, which are most numerous on the darkest parts. The nose is sharp, the ears short and round, the tail pretty equally covered with longish hair. There is a pouch or follicle under the tail, which exudes a yellowish, creamy substance of a very fetid odour; and this odour is

particularly strong when the animal is irritated or alarmed. Hence, apparently, its name *Foumart* ('Foul Marten'), which, with various provincial

Polecat (*Mustela putorius*).

modifications, as *Fulmart*, *Thoumart*, &c., is prevalent in most parts of Britain. The origin of the names Polecat and Fitchet is much more uncertain.

The polecat was much more common in Britain in former times than now, and is almost extirpated from some districts, through the constant war waged against it by gamekeepers and others; and yet it is very prolific, bearing five, six, or even seven young at one birth. It is extremely destructive in the poultry-yard, the abundance present there inviting it to drink blood and eat brains, which seem to be its favourite luxuries. The rabbit is followed by the polecat into its burrow, and its ravages among poultry are partly compensated by its destruction of rats. The tanning of the polecat does not seem to have been attempted. The smell prevents it. The skin is imported from the north of Europe under the name of *fitch*, and is used as a kind of fur, similar but inferior to that of the Marten (q.v., and see *FURS*). To artists the hair of the *fitch* or *fitchet* is well known as that of which their best brushes are made; the hairs used for this purpose being the long hairs already noticed, which grow through the lighter-coloured fur of the animal. The Ferret (q.v.) is a pale-coloured domesticated variety of the polecat. A dark-coloured kind of ferret is commonly regarded as a cross between the polecat and the ferret, and is sometimes called the *polecat-ferret*.

Polemon, a Greek geographer of the 2d century B.C., became an Athenian citizen about 200 B.C. Preller (1838) and Müller (1841) collected the extant fragments of his writings.

Polemoniaceæ, a family of plants, mostly herbaceous, allied to Convolvulaceæ, and containing about 200 known species, natives of temperate countries, and particularly abundant in the north-western parts of America. *Polemonium carolinense* is Jacob's Ladder (q.v.); *Phlox* is also of the family.

Polenta, an Italian dish, the chief ingredients of which are maize meal and salt. Sometimes wheat or chestnut meal is used. It is made into a thick paste, cut into finger-like strips, and baked, generally with cheese. It is eaten either by itself or with roast liver or steamed meat and sauce. A similar dish, called *Mamalliga*, is eaten by Rumanians.

Poles (fr. *polos*, a 'turning-point'), in Geography, are the two extremities of the axis round which the earth revolves; they are therefore situated the one on the north and the other on the south side of the equator, and equidistant from all parts of it, or in 90° N. lat. and 90° S. lat. They are called the north and south poles of the Earth (q.v.).—In Astronomy the poles, which for distinction's sake are frequently denominated 'celestial poles,' are those points in the heavens to which the earth's axis is directed, and round which the heavens seem to revolve. The celestial poles are valuable points of reference to astron-

omers and geographers, so that the determination of their position in the heavens is a matter of the utmost importance. Unfortunately, no stars mark their exact situation (see **POLE-STAR**)—though there is a minute telescopic star only a few seconds from the north pole, which may be employed instead of it in rough observations—and therefore it is necessary to adopt some means for discovering its precise position. This is effected in the following manner: A bright star (generally the pole-star) is selected, and its position in its upper and its lower *Culminations* (q.v.) is accurately noted; the point midway between these two positions of the star is the pole of the heavens. The observation of the star's two positions must be corrected for refraction, and it is for this reason that the pole star is selected, since the effect of refraction is much the same in both positions of the star. The term 'poles' has, however, a wider application, as denoting the extremities of a line passing through the centre of a great circle perpendicular to its plane; thus, we have the poles of the horizon (viz. the zenith and nadir), the poles of the ecliptic, the poles of a meridian; and, in the same sense, the terrestrial and celestial poles are spoken of as the poles of the equator and equinoctial respectively.—**Pole**, in Physics, denotes those points of a body at which its attractive or repulsive energy is concentrated; see **POLARITY**, and **MAGNETISM**.

Polesie, the largest county of Poland, bordering on White Russia. Much of it is occupied by marsh land round the river Pripiet and its tributaries, and the soil is unproductive. Considerably more than half the population are Ruthenians. The capital is Brzesc or Brest-Litovsk (q.v.) Area 16,261 sq. m.; pop. (1921) 879,925.

Pole-star, or **POLARIS**, the nearest conspicuous star to the north pole of the celestial equator. The star which at the present time goes under the name of the 'pole star' is the star α in the constellation of Ursa Minor. By examining attentively the general movement of the stars throughout a clear winter's night, we observe that they describe circles which are largest at the equator, and become smaller and smaller as we approach a certain point (the north pole of the celestial equator), close to which is the star above mentioned. This 'pole-star' is, however, a little less than $1\frac{1}{2}^\circ$ from the pole, and has a small but sensible motion round it. Owing to the motion of the pole of the celestial equator round that of the ecliptic (see **PRECESSION**), this star will in course of time (about 2100 A.D.) approach to within 28' from the north pole, and will then recede from it. At the time of Hipparchus (156 B.C.) it was 12° , and in 1785 $2^\circ 2'$ from the north pole. Its place can easily be found in the heavens, for a line drawn between the stars α and β (called the two *pointers*, from this peculiarity) of the constellation Ursa Major, or the Great Bear, and produced northwards for about $\frac{1}{2}$ times its own length, will almost touch the pole-star. Two thousand years ago the star β of Ursa Minor was the pole-star; and about 2300 years before the Christian era the star α in the constellation of the Dragon was not more than $10'$ from the north pole; while 12,000 years after the present time the bright star Vega in Lyra will be within 5° of it. See star-map at **URSA MAJOR**.

The south pole of the celestial equator is not similarly marked by the near neighbourhood of a bright star, the only star deserving the name of the south pole-star being of the sixth or least visible magnitude.

Polianthes. See **TUBEROSE**.

Police (Gr. *politeia*) in modern times held to be synonymous with the whole body of men employed as constables, or with the system under which such

constables perform their duties in connection with the maintenance of law and order and the prevention and detection of crime. Originally, however, the *politeia* of the Greeks had a much wider signification, and what we now term *police* formed but a part of the regulation of the affairs of a state or country, which was the meaning of the original word. The Greeks, by the adoption of this term, says an old writer on police administration, apparently intended to indicate that the 'execution of those laws which make up public rights, the maintenance of that civil society which is the essence of every city, were two things inseparable from each other.' The strictly executive character of police duties, however, as performed in Great Britain of the 19th century, was not always recognised in ancient times, and whether at Athens, under officers called *archon* or *nomophylax*, or at Rome, under consuls, pretors, questors, censors, or *ediles*, the judicial functions of a police-magistrate, or the responsibilities of a public prosecutor, devolved to a greater or less extent upon those officials who were entrusted with police administration. It is difficult to refer to any country in which the separation of executive from judicial or magisterial functions has so strictly been carried out as would appear to be required under our modern interpretation of police duties in England. The French system of police, which is based on the old Roman administration, mingles to a very considerable extent executive with judicial functions. The same remark applies to continental police administration generally; and even in the great dependency of British India, which is governed by English law, the district magistrate, who is *ex officio* head of the police within the limits of his jurisdiction, is also a judicial officer with extensive powers. In the capital of England itself, where the distinction between executive and magisterial functions is specially marked, the chief of the police is still, by virtue of his office, a justice of the peace, although the exercise of his powers in that capacity is restricted by certain conditions.

The existing system of police administration in the United Kingdom is of comparatively recent origin; it arose within the 19th century, and in many instances was developed within the reign of Queen Victoria. In the early period of English history there was no such institution as a separate body of police. The responsibility for maintenance of the peace was imposed on each hundred or tithing, and the members of these divisions were held jointly liable for the consequences of any infractions of the laws which took place within their limits. Self-interest made every member of the association a constable; and although the collective responsibility of the tithing or hundred was for executive purposes represented by the headman of each, such transfer of liability was not recognised by the law when any penalty for breach of the peace was incurred. As time went on the place of the headman of the local division was taken by a constable or constables in the various villages or parishes of the country. In the larger towns the members of the various wards at first maintained order and kept watch within their various limits; gradually separate watchmen, very inadequately paid, were introduced; but the inefficiency with which watch and ward duties were performed, and the impunity with which crimes were committed, were conspicuous, and in no place more so than in the metropolis itself. During the 18th century spasmodic attempts were made to improve the administration in London, both as regards prevention and detection of crime. Horse patrols were introduced; a detective staff was organised; but the whole system was fragmentary and disjointed, and the results attained

under it were pre-eminently unsatisfactory. The decrepitude of the old 'Charlies,' as the watchmen were called, and their inability to afford protection to the inhabitants of London, were proverbial; and as to Edinburgh we may read in the pages of the *Heart of Midlothian* Sir Walter Scott's description of 'that black banditti,' the 'City Guard,' who were in his days the 'alternate terror and derision of the petulant brood of the High School,' and objects of scorn to the citizens generally. At last in 1829 Sir Robert Peel constituted the Metropolitan Police, abolishing local police administration in the metropolis outside of the narrow limits of the City of London itself, and placing the control of the new force in the hands of the Secretary of State. 'The new guardians of the peace in the metropolis, retaining the comparatively ancient name of constable, were called police-constables, and were in a sense a development of the tithing-man of old; but they resembled him even less than a member for a metropolitan borough resembles the burgesses who appeared before the chief-justices at Westminster with a statement of accounts in the reign of John. Yet the stages of growth are sufficiently well marked—from the responsibility of the tithing to the responsibility of its head, from the functions of the head borough or tithing-man to the functions of the constable, from the election of a constable to the election of a plurality of constables, and finally from a plurality of constables, deputy constables, and watchmen, under parochial or other local authority, to a plurality of constables under the central authority of a Secretary of State' (Pike's *History of Crime in England*, ii. 460).

By the Municipal Corporations Act, 1835, every municipal borough was required to appoint a police force: a number of special constables were also to be annually appointed to act when occasion arose. These provisions were continued in the Municipal Corporations Act, 1882. In 1839 the justices in quarter sessions, who then formed the local administrative body for each county, were empowered by the County Police Act, 1839, to establish a permanent and salaried police force, and in 1856 the establishment of such a force was rendered obligatory for each county by the County and Borough Police Act of that year. Under this measure the establishment of an effective police organisation for the whole country, commenced by the Metropolitan Police Act of 1829, was completed. Since that time the character of the police authority controlling the county police forces has been changed by the Local Government Act, 1888, which created elective councils for the government of the counties and transferred the control of the county police forces to the standing joint committees, composed of an equal number of representatives of the justices and of the newly-formed county council. Apart from this, the system remains to-day much as constituted by the statutes of 1829–56. While, however, the several forces are still independent one of another, much has been done in recent years to introduce common methods, closer co-operation and more uniform conditions of service, and great advances in the efficiency of the service have been made in a variety of ways. Provision is also made by which any force can be supplemented in an emergency by men lent from another force, and members of any force added temporarily to another force under this provision have all the powers of constables of the district in which they are acting.

It is, of course, necessary that constables should be more or less drilled to enable them when called upon to act together in bodies, but the force is, in its essence, constitutional, and performance of duty, civil and non-military. In serious emergency the aid of the military forces of the crown can be re-

quisitioned by magistrates to supplement the police in the maintenance of law and order, but such occasions, happily, are of rare occurrence.

The total strength of the police forces in England and Wales is shown in the following table:

Date.	Authorised Establishment	Population	Population per Constable.
1892	40,596	29,002,525	712
1902	45,544	32,527,843	714
1912	53,112	36,070,492	679
1922	56,832	37,884,950	667
1925	57,043	37,884,950 *	664

* Census of 1921.

The above figures represent the total authorised establishment, apart from police specially employed for the protection of dockyards or other establishments at the expense of the parties concerned. These additional police numbered 2814 in 1925. During the Great War, when some 18,000 men served in H.M. Forces and recruiting was suspended, the strength of the police was much below the authorised establishment, and the force was supplemented by large numbers of special constables.

The number of police in proportion to population varies considerably in different police districts, mainly by reason of the varying needs and circumstances of the localities concerned, as is illustrated by the following figures for 1925:

Police District.	Authorised Establishment, 1925	Population (1921 census)	Population per Constable.
Metropolitan	19,277	7,166,492	357
Liverpool	1,732	802,940	464
Manchester	1,395	729,307	524
Birmingham	1,586	919,444	580
Leeds	687	458,232	667
Herts	576	238,147	601
Gloucestershire	444	380,772	858
Rucks	216	214,234	992
Cornwall	271	306,869	1132
Monmouth	263	328,136	1263

The total net expenditure on the police, which was 6½ millions sterling in 1911–12, was approximately 18 millions in 1924–25, the increase in cost being due in the main to the greatly improved rates of pay and pensions introduced since 1919.

Metropolitan Police.—The Metropolitan Police District (exclusive of the City of London, which has a separate police force) extends over a radius of approximately 15 miles from Charing Cross, including the whole of the counties of London and Middlesex, and parts of the counties of Kent, Surrey, Essex, and Herts, with a total area of about 700 square miles and a population estimated at nearly 7½ millions. Under 23 and 24 Vict. chap. 135, Metropolitan Police are also employed in some of H.M. dockyards and principal stations of the War Department. The total authorised strength of the Metropolitan Police in 1925 was 19,277 officers and men of all ranks, exclusive of 1173 men employed outside the Metropolitan Police District at dockyards, &c. The total net expenditure on the Metropolitan Police is at the rate of approximately 6 millions sterling per annum, or about 16s. per inhabitant.

The system of administration is a development of the principle on which the force was first established by Sir Robert Peel—'unity of design and responsibility of its agents.' The control of the force (subject to the general authority of the Secretary of State) is vested in a commissioner who is appointed by the Crown, assisted by a deputy commissioner, three assistant commissioners, three deputy assistant commissioners, and five chief constables. The whole of the Metropolitan Police District is divided into twenty-two divisions, each having a force of several hundred men in charge of a superintendent, aided by a chief inspector and other officers. There is in addition a division specially engaged in policing the river Thames. The superintendent is responsible

for all the details of police administration within his division. For executive purposes the divisions are brigaded into four police districts, each comprising several divisions and in charge of a chief constable. Each principal station is in direct communication by telegraph with the headquarters office, and there is an elaborate system of telephone communication linking the various stations.

The general control of the whole force is exercised from the central office of the commissioner at New Scotland Yard, which deals with all matters affecting the force as a whole, or of national, as opposed to local, concern. At this central office are also the headquarters of the Criminal Investigation Department, which is specially concerned in the detection of crime. Local crime is dealt with by C.I.D. officers attached to the several divisions, while the conduct of special cases is in the hands of the headquarters staff, which is specially in charge of one of the assistant commissioners and a deputy assistant commissioner. The strength of the C.I.D. is about 800 men.

City of London Police.—The City of London, which covers an area of about one square mile in the centre of the county of London, has a separate police force, under the control of a commissioner, established partly by special statutes and partly by virtue of extensive powers of local government derived from ancient charters. The strength of the force is about 1100 men.

County and Borough Police. There were in 1925 sixty county forces and one hundred and twenty-two borough forces with a total authorised establishment, all ranks, of 36,604, apart from 1622 additional constables employed as dock police, colliery police, &c., at the expense of the firms or individuals concerned. The individual forces vary widely in size, the authorised establishments ranging from 2000 men down to 11 men of all ranks. All these forces are under the control of the local police authorities. In the county forces, as already mentioned, the police authority is the Standing Joint Committee, composed half of representatives of the justices and half of representatives of the county council. In the boroughs, the police authority is the Watch Committee, which is a committee of the town council elected annually. Each force is commanded by a chief constable, but the powers of the chief constables of counties are wider than those of borough chief constables. In the former, the chief constable has sole responsibility for all appointments and promotions in the force, and for discipline, whereas in the boroughs the responsibility in these matters is vested in the Watch Committee, though in practice it is delegated in greater or less degree to the chief constable.

Conditions of Service and Financial Provisions.—

While the several police forces are independent one of another, all are subject in greater or less degree to the supervision of the Home Office. In the case of the Metropolitan Police, as already mentioned, the Secretary of State is himself the police authority. Under the County Police Act, 1839, the Secretary of State has always had power to make rules applicable to the county forces, but this power was extended to all forces by the Police Act, 1919, which provides that the Secretary of State may make regulations as to the government, mutual aid, pay, allowances, pensions, clothing, expenses and conditions of service of the members of all police forces in England and Wales, and all police authorities are required to comply therewith. Under these powers a comprehensive code of regulations, applying to all forces, and dealing with such matters as pay, allowances, discipline, promotion, hours of duty, &c. was made in 1920; in 1921 the statutes regulating the police pensions

were consolidated in the Police Pensions Act of that year. Thus the police in all forces, Metropolitan, City of London, County, and Borough, now serve under conditions which are substantially uniform throughout the country.

The expenses of the police are defrayed from the Police Funds of the several forces, and are met partly from local rates and partly by contributions from the Exchequer. These contributions consist of statutory grants from certain assigned revenues, supplemented by a direct grant, voted annually by Parliament, the amount of the latter being calculated so as to bring the total Exchequer contribution up to one half the total net expenditure. The Metropolitan Police Fund receives in addition a special direct contribution in respect of certain services of imperial, rather than local, character. The City of London force does not share in the statutory grant. The payment of the statutory grants is contingent on the issue of an annual certificate by the Secretary of State that the force has been maintained in a state of efficiency, and the payment of the voted grant is subject to the Secretary of State being satisfied that the force is fully and properly administered, and that the requirements of the police regulations as to the pay and allowances, &c. of the force have been complied with. For the purpose of the Secretary of State's certificate of efficiency every county and borough force is inspected annually by one of H.M. Inspectors of Constabulary, appointed under the County Police Act, 1856. The total net expenditure on the police in England and Wales which, as already mentioned, amounted in 1924–25 to 18 millions, was met approximately as follows: From local rates £9,150,000; from assigned revenues, £2,900,000; from direct grant, £5,950,000.

Police Federation.—By section 1 of the Police Act, 1919, already referred to, there was also established 'for the purpose of enabling members of the police forces in England and Wales to consider and to bring to the notice of the police authorities and the Secretary of State all matters affecting their welfare and efficiency, other than questions of discipline and promotion affecting individuals,' a representative organisation, designated the Police Federation, to which the members of all forces below the rank of superintendent belong by virtue of their office. There is in each force a local representative body, the Branch Board, for each rank, and Central Committees for each rank are appointed at annual conferences attended by delegates from all forces. These Central Committees have the right to submit representations to the Secretary of State in writing or by way of deputation, and they are consulted from time to time by the Secretary of State on matters affecting the interests of their ranks.

Auxiliary Police Services, &c. In case of emergency, the police of any force may be supplemented, as already mentioned, by police borrowed from another force. In addition, provision may be made, and is made by many police authorities, to keep a register of police pensioners and other suitable persons who undertake to join the force for temporary service if called upon to do so. Men so registered receive in some forces a small retaining fee: when called upon for duty they act in all respects as ordinary members of the force and wear the usual uniform and accoutrements.

Another important method of supplementing the police force in time of emergency is, as it has been since the reign of Charles II., the employment of special constables. Special constables are ordinary citizens of good character who are sworn in to assist in the preservation of order, and as such they enjoy all the powers and privileges of a regular constable. By the Municipal Corpora-

tions Act, 1835, every borough was required annually to appoint a number of persons to serve as special constables, who, if necessary, might be called on to act by the warrant of a Justice of the Peace, and this provision is retained in the Act of 1882. In counties it was formerly the case that special constables could only be enrolled on information sworn before two or more justices that tumult, riot, or felony was to be apprehended (Special Constables Act, 1831, 1 and 2 Will. IV. chap. 41). Now, in virtue of the Special Constables Acts, 1914 and 1923 (4 and 5 Geo. V. chap. 61, and 13 and 14 (Geo. V. chap. 11) there is power to appoint and maintain a force of special constables in all police districts and at all times. Special constables appointed under this provision do not ordinarily receive any retaining fee or other payment, but when called upon for duty are eligible to receive allowances by way of repayment of expenses, and if incapacitated by injury received on duty are entitled to pensions or gratuities. Unless other special provision is made by order of the Secretary of State, special constables, like the regular police, act at the disposition and under the control of the Chief Constable.

Police in Scotland.—It is only recently that the same acts relating to the police have applied both to England and Scotland. Earlier legislation dealt with each country separately, though it followed the same general principles in each case.

The principal statute regulating police in Scottish counties is the Police (Scotland) Act, 1857, which provides for the establishment of a police force in every county, except Orkney and Shetland. (The latter counties have police forces, but they do not come within the Police Acts, are not subject to the police regulations referred to hereafter, and do not share in the Exchequer grants.) As in England, the police authority in counties is the Standing Joint Committee.

The corresponding principal statute regulating the police in burghs is the Burgh Police (Scotland) Act, 1892, which supersedes earlier Acts of 1833, 1847, 1850, and 1862. Burghs which have a population of not less than 20,000 may maintain separate police forces, but some such burghs are policed by the police force of the county in which they are situated, and some have consolidated their police with the county force. Other burghs are policed by the county, but burghs which at the passing of the act maintained a separate force, and had at the census of 1891 a population of not less than 7000, retained their separate forces. Of the 201 Scottish burghs, 27 have separate forces. The police authority in burghs is the Town Council.

The Act of 1892 does not apply to the five most important burghs in Scotland, namely, Edinburgh, Glasgow, Aberdeen, Dundee, and Greenock, and the police forces in these burghs are regulated by a series of local acts, the provisions of which correspond generally to those of the Burgh Police Act.

In Scottish burghs there is no body corresponding to the Watch Committee referred to in the previous section of this article. The Town Council is the sole police authority in a burgh which maintains a separate force.

The total authorised strength of the police forces in Scotland on 31st December 1925 was 6553. The number of vacancies existing at that date was about 100. In addition there were 162 additional constables, that is, constables employed and paid for by private individuals, firms, and harbour and other authorities. As in England, the strength of the several forces varies widely. The force of the least populous county has a total strength of 8, and that of the most populous a strength of 391. The strength of the burgh forces varies from 9 to 2247.

In Scotland special constables are appointed in counties by the Standing Joint Committee, and in burghs by the magistrates, and serve under the same general conditions as special constables in England. Early legislation followed a different course in the two countries, but the Acts of 1914 and 1923, to which reference is made above, applied to both countries, and the orders in council issued under the last-mentioned act, which deal *inter alia* with allowances, pensions, and gratuities to special constables, are in similar terms for both countries. The number of special constables now enrolled in Scotland is about 22,000. The arrangements regulating the loan of police from one force to another and the engagement of temporary constables are similar to those in force in England, but it is not the practice in Scottish forces to pay a retaining fee to men who undertake to join for temporary service.

The Secretary for Scotland is the central authority for the administration of the police in Scotland, and his powers are similar to those of the Secretary of State in England. There is, however, no force in Scotland to which he stands in the same relation as the Secretary of State to the Metropolitan Police.

The Police Act of 1919 applied to both countries, and there is a Scottish Police Federation constituted in all respects in the same manner as the English Federation. A code of regulations has been issued for Scotland which resembles very closely the English code described in the previous section of this article. By the Police Pensions Act, 1921, the schemes of pension for the police of the two countries, which had up to that date been on a different basis, were revised and assimilated.

As in England, the cost of the police is met in part from the rates and in part from Exchequer contributions. Exchequer grants bear the same proportion to expenditure and are distributed on the same conditions in each country. The total net expenditure on the Scottish police in 1924-25 was £1,919,541, which was made up as follows: From local rates, £959,800; from government subsidies, £959,741.

Police in Ireland.—Formerly there were two police forces in Ireland—the Royal Irish Constabulary, a semi-military force under the control of the Irish Government, with jurisdiction throughout the whole of Ireland except the city of Dublin and its adjacent suburbs; and the Dublin Metropolitan Police, a civil force similar to the Metropolitan Police in London. These two forces no longer exist. The police in the Irish Free State and Northern Ireland are now under the control of the respective governments.

Polidori, JOHN WILLIAM (1795-1821), born in London, took his M.D. at Edinburgh, and in 1816 was appointed travelling physician and secretary to Byron, to whom he falsely ascribed his own story of *The Vampire* (1819). Owing to gaming losses, he poisoned himself. See his *Diary*, edited in 1911 by his nephew, W. M. Rossetti.

Polignac, an ancient French family, which claims to derive its name from a castle—the ancient *Apollinacum*—in the department of Haute-Loire, and which since the 9th century possessed the district of Velay. Among its most famous members was Cardinal Melchior de Polignac (1661-1742), who was employed in diplomatic missions in Poland and at Rome, and received a cardinal's hat after acting as plenipotentiary of Louis XIV. at the peace of Utrecht (1712). From 1725 till 1732 he was French minister at the court of Rome, and he was appointed Archbishop of Auch. Polignac succeeded Bossuet at the French Academy in 1704, and left unfinished the *Anti-*

Lucretius (1745), a poem intended for a refutation of Lucretius.

Some other members of the Polignac family are more notorious than noteworthy.—In the reign of Louis XVI. Iolanthe-Martine Gabrielle de Polastron, Duchesse de Polignac (born 1749; died at Vienna, 9th December 1793), and her husband, Jules, Duc de Polignac (died at St Petersburg, 1817), grand-nephew of the cardinal, were among the worst, but unhappily most favoured, advisers of Marie Antoinette. They obtained vast sums of the public money from their royal master and mistress, and were largely responsible for the shameful extravagance of the court. The Polignacs knew how they were hated, and were the first of the *noblesse* to emigrate. From the Empress Catharine of Russia the duke received an estate in the Ukraine, and did not return to France at the Restoration.—His son, AUGUSTE JULES ARMAND MARIE, PRINCE DE POLIGNAC, was born at Versailles, 14th May 1780. On the Restoration he returned to France; became intimate with the Comte d'Artois, afterwards Charles X.; from his devotion to the policy of Rome received from the pope in 1820 the title of Prince; was appointed ambassador at the English court in 1823; and finally, in 1829, became head of the last Bourbon ministry, in which capacity he promulgated the fatal ordinances that cost Charles X. his throne. He then attempted to flee, but was captured at Granville on the 15th of August, was tried, and condemned to imprisonment for life in the castle of Ham, but was set at liberty by the amnesty of 1836. He took up his residence in England, but died at St Germain, 2d March 1847. He was a puzzle-headed man; 'a mere idiot' Guizot called him to Bishop Wilberforce.—His son, Prince Armand (1817–90), was a leading monarchist.

Poliomyelitis. See PARALYSIS.

Polishing. See DIAMOND, GLASS, &c.

Polishing, FRENCH, is the usual method of polishing furniture. Simple varnishing with copal or mastic varnish, put on with a brush, produces a comparatively uneven surface which soon wears off with friction. A French-polished surface, on the other hand, is beautifully smooth and glossy, and very durable. The process, which of course differs with the quality and grain of the wood, usually consists of staining, oiling, filling, and polishing. The wood is stained if necessary; good woods are usually left unstained—then rubbed over sparingly first with raw linseed oil, next with a preparation of whiting and methylated spirits to fill in the grain. Thereupon several coats of polish are applied with the rubber. The polish consists chiefly of shellac and methylated spirits, to which various gums and the requisite colouring are added. Finally the work is rubbed with methylated spirits to remove traces of oil and give a lustré. An 'egg-shell' finish is given to the surface by rubbing over the ordinary French-polished surface with pumice and linseed oil. The pads or rubbers used are either of flannel or cotton-wool covered with soft rag. A very little linseed oil is used as a lubricant during operations. Good work requires care, time, experience, and freedom from dust.

See *The French Polisher's Handbook* (1918); A. W. Parkhouse, *Practical Polishing and Staining* (1922); and the articles JAPANING, VARNISH.

Polishing Slate, a siliceous rock of organic origin, consisting largely of the remains of diatoms. It is white or yellowish in colour, and is distinguished from diatomaceous earth by its slaty texture.

Politian. ANGELO POLIZIANO (Latinised *Politianus*) was born at Montepulciano in Tus-

cany, on the 14th July 1454. His real name was Ambrogini, but, in accordance with a common practice at the Renaissance, he early called himself by the Latinised form of his native town, which Italianised into Poliziano is the name by which he is known in his own country. His father, Benedetto Ambrogini, a jurist of some distinction, was assassinated by certain of his fellow-citizens, and left his widow and five children so scantily provided for that, even after Angelo the eldest had given the most signal proofs of his genius, he was on the point of being taken from his studies and put to a trade. At the age of ten he was sent to Florence, then under Lorenzo de' Medici, the brilliant centre of the Italian Renaissance. Here he had as his teachers the most famous scholars of his time, the Greeks Argyropoulos and Kallistos, and the Italians Landino and Ficino. His progress in the ancient languages, the special studies of the period, was extraordinary even in that age of precocious talents. By his sixteenth year he wrote epigrams in Latin and Greek that excited the wonder of his teachers. At seventeen he began the translation of the *Iliad* into Latin hexameters, a work which it had been the ambition of all the Italian humanists to achieve. The first book had already been translated by another scholar, and Politian at different periods carried on the work to the end of the fifth. By his success with the second book he became known as the 'Homeric youth', and attracted the attention of the great Lorenzo himself, who now stood his firm friend and patron. Thus secure of a settled position his life was thenceforward devoted to incessant study, and he was soon recognised as the prince of Italian scholars, and the most remarkable literary genius of his time. At the age of thirty he became professor of Greek and Latin in the university of Florence, and the fame of his prelections drew students from every part of Europe, among whom, by reason of their own services to learning, Reuchlin, Grocyn, and Linacæ may be specially mentioned. Politian was also entrusted with the education of Lorenzo's sons, Piero and Giovanni (afterwards Leo X.); but their mother Clarice, who had excellent reasons for doubting the great scholar's fitness to be the director of her boys, insisted on his being removed from their immediate superintendence. In such occupation, varied by occasional visits to other towns of Italy, Politian lived at Fiesole in a villa assigned to him by Lorenzo, whose familiar intercourse he daily enjoyed. The death of that prince in 1492 was the most serious trial of his life, and he mourned his death in a Latin elegy, which has been described as unique alike in form and feeling in modern Latin poetry. Two years later he himself died during the temporary supremacy of Savonarola, whose religious zeal was directed against every principle of that pagan revival which it had been the life's work of Lorenzo and Politian to forward. Politian's epitaph on his tomb in San Marco, at Florence, is so entirely in the ironical and sceptical spirit of that movement of which he was so brilliant a representative that it fitsly closes any account of himself. It is as follows: 'Politian lies in this grave, the angel who had one head and, what is new, three tongues.'

Politian has the double distinction of being both a scholar of the first rank and a poet of high merit alike in Latin and in his mother tongue. Of his industry as a scholar his translations of classical authors (Epictetus, Herodian, Hippocrates, Galen, Plato's *Charmides*, to mention a few of the long series) are ample evidence, while his edition of the *Pandects* of Justinian is regarded by modern scholars as excellent even when tried by the latest tests. His original works in Latin fill a thick and

closely-printed quarto, half of which is made up of twelve books of letters, and the rest with miscellanies in prose and verse. Among Neo-Latin poets Politian holds perhaps the first place, his peculiar distinction being that, while he is not careful of classical purity, he has charged his verse with his own individual thought and feeling. In Italian literature also he takes a high rank, both in virtue of his own poetic production and as having at a critical period given an impulse to the cultivation of the Italian language. Before him the Italian humanists regarded their native tongue simply as a bastard Latin, which might serve the needs of the people, but was beneath the attention of scholars. The weight of Politian's name and example moved them to think differently, and thenceforward Italian was secure of a place among the other modern literatures. Of his productions in Italian his *Orfeo* deserves special mention as having been the first secular drama in the language. As to his personal character, Politian had in full measure the two great blemishes of the scholars of the Revival of Letters, and notably those of Italy. He was addicted to the lowest forms of vice, and he knew no bounds to his abuse of those who had the ill-fortune to offend him.

See *Opera Ang. Politiani* (Florence, 1499); *Le Stanze, Porfirio e le Rime di Messer Ang. Ambrosini, illustrate da Giosep. Carducci* (Florence, 1863). For accounts of Politian, see Roscoe, *Life of Lorenzo de' Medici*; J. A. Symonds, *Renaissance in Italy*, vol. ii.; Von Reinmunt, *Lorenzo de' Medici* (vol. ii. Eng. trans. 1876).

Political Economy. The name 'Political Economy' dates from 1615, having been first used in this special sense, as distinguished from domestic economy and from political theory, by Montchretien de Vatteville in his mercantilist pamphlet entitled *Traité de l'Economie Politique*. Montchretien's use of the term is, however, somewhat different from the modern use.

Nature and Scope of Political Economy.—Political economy has been variously defined, but the *nature* and *scope* of the study to which the term now applies cannot be better indicated provisionally than by the full title of Adam Smith's great work, *An Inquiry into the Nature and Causes of the Wealth of Nations*. Slight consideration will suffice to show that such an inquiry has inevitably two aspects: first, the theoretic and positive aspect, namely, the nature of wealth and the principles or influences *actually* determining its production, distribution, exchange, and consumption within the community considered; and second, the practical or ethical aspect, the methods which may or should be adopted by the community in these connections so as to attain certain economic ends or political ideals. In practice undoubtedly these two aspects are inseparably connected, but logically and for purposes of study they must be kept distinct. The economic scientist or the *science* of political economy is concerned with the first aspect. The second aspect constitutes the *art* of political economy, and is more properly the pre-occupation of the social reformer or the statesman as a branch of the art of government. Until the time of Adam Smith the two aspects were not distinguished, but on the whole it was the second aspect which the term political economy indicated. Political economy, was regarded as part of the art of government, and meant in the political sphere the same as domestic economy in the sphere of the household, namely, an adaptation of the economic resources for the good of all concerned. Adam Smith made no explicit separation between the science and the art of political economy. He obviously regarded them both as parts of the same inquiry; but he treated them, in fact, separately, and thus laid the foundations of the science.

N. W. Senior in 1837 was the first writer to make a clear division of political economy into (1) the theoretical, which 'explains the nature, production, and distribution of wealth'; (2) the practical, of which the office is 'to ascertain what institutions are most favourable to wealth.' Some years later, in a treatise written originally for the *Encyclopædia Metropolitana*, Senior, conscious that he is narrowing down the traditional meaning of the term, proposed to confine the name political economy to the theoretical branch, leaving the practical branch to be absorbed in the general art of government. He did this, not because he failed to recognise the importance of government action in the economic sphere, but because investigation in that sphere could be pursued like investigation in other spheres, quite independently of the practical applications which might be made of the knowledge thus gained. He further insisted that the practical applications of economic truths for the purpose of furthering the general welfare of society was not the business of the economist, but of the statesman, who in framing legislation must have in view the welfare of the state as a whole, taking into consideration many other factors than the merely economic. Senior's view of the scope of political economy has come to be, on the whole, the prevailing view of economists in Britain. The failure to grasp this fact has led to much confusion as to the nature of economic 'laws.'

Economic Laws.—These laws are like the laws of the physical sciences, merely statements of facts or tendencies. They indicate certain causal relations which exist under certain specified conditions. They are not in any sense precepts for conduct or rules for action; therefore, although the tendencies which they indicate may be overlooked or neglected, the laws cannot in any sense be 'disobeyed.' Rules for action may be laid down by the *art* of political economy, but these depend for their validity on the validity of the social or political end which they are framed to promote. Such rules may be regarded as political precepts and may take the form of legal enactments, but they must not be confused with economic *laws* in the positive and scientific sense.

Method of Political Economy.—The scope assigned to political economy has an important bearing on the much-controverted question of the method of economic investigation, viz. whether the method should be 'deductive,' which in political economy means, mainly, basing conclusions on certain fundamental facts of human nature, or whether it should be 'inductive' and historical, arriving at conclusions only after a study of all the relevant facts. Here it need only be said that the two methods are now admitted to be supplementary rather than distinct, and in themselves have different degrees of usefulness in different cases. In so far, however, as the scope of the subject is conceived to be theoretic, the arriving at general principles, the deductive method supported and verified by induction will yield the most fruitful results. As a natural consequence the English school of political economy since Ricardo has been in the main deductive in character. On the other hand, if the scope is conceived to be both theoretic and practical, the method must be primarily historical, since the aim is not merely the establishment of general principles, but much more the moulding of existing social conditions according to some economic or social ideal. This, on the whole, is the view of political economy in Germany, and the German school of economists is preponderantly historical in character.

History of Political Economy.—The science of political economy is a branch of the study of man. Man is a creature with many needs, which he seeks

to satisfy by applying his labour to the nature by which he is surrounded. These needs are not a fixed quantity, but grow and change with the development of society; and man's devices for their satisfaction receive a corresponding development. In the growth of these needs and of the devices to satisfy them we can trace the economic development of the human race. Political economy may be regarded as the systematic and comprehensive study of the phenomena connected therewith. There have been economic facts therefore ever since the origin of man, although there was no real science of political economy till it was constructed by Adam Smith and his forerunners in France in the 18th century. Science generally is the systematic study of facts which existed before the study began. Yet, while political economy did not exist as an independent and comprehensive branch of human knowledge before the 18th century, much attention had been given to particular economic facts. Various economic problems had received great and serious attention.

The history of political economy naturally falls into four divisions—the *ancient*, the *medieval*, the *mercantilist*, and the *modern*. We shall treat them briefly in their order.

(1) *The Ancient Period*.—As in other sciences, the first notable efforts in economic reflection were made by the ancient Greeks. The leading Greek thinkers who handled economic questions were Plato, who in the economic as in other spheres represented the idealism of the ancient world; Aristotle, the exponent of scientific realism; and Xenophon, who expounded the plain common sense of his time and country. Of the problems which they treated with the insight peculiar to their race we may mention the following: the economic aspects of the origin of society; the division of labour; the function of money; economics of slavery, which they considered a natural thing; property and the related question of communism; the dependence of political change and of revolution on economic causes; the population question. On these and other subjects the teaching of the great Greek writers is most valuable; nor is its value lessened by the fact that their discussion of economic facts forms only a part of the science of politics. And, while the conditions of the modern world differ so vastly from the Greek world, the economic views of thinkers like Plato and Aristotle will always have an interest for us, inasmuch as the solid groundwork of human nature continues substantially the same through the changing conditions of history.

Roman economics had no special interest or originality. The main contribution of the Romans in connection with political economy was to give legal form to the prevalent ideas of property.

(2) *The Medieval Period*.—During this period there was little discussion on economic problems that could now be called scientific. The most interesting feature of the economic views that then existed was the influence exerted on them by Christian teaching. This influence was most profound and greatly affected also the economic thinking of subsequent times. The influence of Christianity was especially manifest in relation to the weak and oppressed classes. It tended to soften and then to abolish slavery and serfdom; it raised the position of women and gave a new refinement to family life; the care of the poor became a first duty of men and of human institutions. The ideas and institutions of property prevalent in the Roman world, which were often harsh, severe, and cruel, were corrected by the spiritual ethics of Christianity. To the struggling and half barbarous feudal world it taught a nobler life and a higher conception of duty in the economic as in other spheres.

It inculcated righteousness and charity, forbade usury and luxury, exalted poverty and resignation. In their opposition to the rigorous ideas of property some of the Fathers even advocated communism. The medieval period was a time of confused struggle, in which Christian ethics were often opposed not only to the tough and warlike egoism of the feudal races, but to the harsh economic ideas that were incorporated in the Roman law.

(3) *The Mercantilist Period*.—Feudal communities were superseded by centralised monarchies; and this great political change was an organic one, being attended by important changes in other spheres. The church lost much of its power. The feudal nobles were transformed into courtiers. The feudal militia gave place to professional armies in the pay and in the immediate service of the monarch. For the maintenance of the army and of the court and other dependents of the centralising ruler it was necessary first of all to have a sufficient revenue. And, as the old revenue in kind was neither convenient nor effective, it was found particularly desirable to have a revenue in money. Accordingly it was one of the greatest and most pressing functions of the statesmanship of that time to foster and to secure an ample revenue in money. The rise of the Colonial System (q.v.) consequent on the discovery of America and of the sea-route to India, the great expansion of commerce thence resulting, the growth of manufactures, the development of the banking system, all these were regarded as elements in the strength of the centralised state, and were made subservient to its policy. Under these circumstances it was natural that special attention should be paid to the balance of trade; that trade should be so regulated by statesmen as to secure for their own country a good balance of the precious metals. Thus it became a special note of economic theory to place an exaggerated value on the precious metals. The Mercantile System (q.v.) was an expression of this exaggeration in the sphere of political economy. Economists differ as to the precise meaning and application of the phrase, and indeed it had no very precise meaning or application. The meaning of the phrase will naturally vary according as we confine the application of it to the exaggeration to which it specifically relates or extend it to the whole system of which the exaggeration was a conspicuous feature. But there can be no doubt that the system grew out of the needs and circumstances of the time. Its chief exponents were Bodin and Montchretien de Vatteville in France, Antonio Serra in Italy, and Thomas Mun in England. In practical statesmanship it is associated chiefly with the great names of Cromwell and Colbert.

(4) *The Modern Period*.—I. *Adam Smith*.—Even during the prevalence of the mercantile system a new way of thinking on economics had arisen in England and France. Its keynote was freedom, and it too was an organic part of the social and political evolution of the time. The exponent of the new system was Adam Smith, but he was only the chief representative and ennobling point of a movement which had been growing for more than a century. In England men like Locke, Joshua Child, William Petty, and Dudley North had been struggling more or less successfully towards a similar point of view. In France the school of Physiocrats, headed by Quesnay, had taught many of the new ideas; in particular they had been set forth with perfect lucidity and conciseness by Turgot in his *Réflexions sur la Formation et la Distribution des Richesses* (1766). In fact, Turgot's little book might be regarded as the first scientific exposition of political economy. Adam Smith's achievement was to give the fittest form to ideas

which were becoming current among the most progressive minds of his time. If Turgot's work may be regarded as the first brief statement of political economy, Smith's *Wealth of Nations* (1776) was the first thorough and comprehensive exposition of the subject by a man who had ample leisure and capacity, a remarkable knowledge of history, and an adequate philosophic training.

The teaching of Adam Smith was by himself well defined as a system of natural liberty. In view of the ill-judged or antiquated regulations of the past he advocated liberty; and to all that was artificial in such regulation he opposed a natural order, thus following the school of Rousseau in the return to nature from a perverted civilisation. Indeed, both in his assertion of freedom and in the appeal to nature, Smith was only applying to political economy principles that were dominant in other spheres of thought. Smith also followed the example of his predecessors, and showed himself in harmony with the new era, in regarding labour as the source of wealth. With regard to other economic questions relating to capital, rent, interest, &c., Smith has said much which, though it has not always gained the assent of subsequent economists, has at least had the merit of starting important discussion. Smith's pre-eminence as an economist lies in the fact that he summed up and presented in lucid perspective the best economic thought of the times preceding, while his writings were the starting-point of all further development.

The Modern Period—II. Malthus and Ricardo.

—The contributions of Malthus and Ricardo to political economy are largely the result of a change in social conditions after Adam Smith wrote, and are best understood in connection therewith. An increasing population, an insufficient food-supply, and an unwisely administered poor law led Malthus to inquire into the nature and causes of poverty as Adam Smith into those of wealth. In his *Essay on Population* (1798) he propounded the theory that population tended to press on the means of subsistence unless held in check by vice, misery, or the fear of both. He also discovered what is usually called the Ricardian theory of agricultural rent, that rent is the effect and not the cause of price, and is a surplus due to differences in the fertility of land. This theory had been stated by James Anderson in 1775, but in conjunction with Malthus's population theory it now assumed a new significance. Ricardo first came into prominence with the publication of his *Letters on the High Price of Bullion* (1809), which showed him to have an unrivalled grasp on problems of currency; but he owes his great influence on economic thought to his *Principles of Political Economy and Taxation* (1817). Ricardo had studied the *Wealth of Nations*, and from it he had abstracted certain fundamental ideas. Using these as a basis, he reared up a structure of economic theory which seemed to have a universal and absolute application. His fundamental assumptions are: pure self-interest as a motive of conduct, and perfect mobility of labour and capital. He developed the theory of rent, and made it with a new theory of value the centre of a theory of distribution of wealth between the three parties concerned, the labourers, the employers, and the landlords. The value of manufactured articles, he maintained, is determined mainly by the quantity of labour necessary to their production, and of agricultural products by the quantity of labour necessary to the cultivation of the worst land actually cultivated. As the margin of cultivation extended to inferior lands, rents rose, profits diminished, while the real wages of labour remained stationary, being determined by the necessities of subsistence. Ricardo himself recognised qualifications of this theory, but they are insufficient and

they are not explicitly stated, and by his ardent followers they were generally omitted altogether. Ricardo is thus popularly credited with a 'labour theory of value' and an 'iron law of wages' which he had no desire to maintain. The other writers of this period, McCulloch and James Mill, followed Ricardo closely, and, although Senior followed him with reservations, the importance of these reservations was not generally recognised until a later period. In this period French and German writers began to acquire greater influence, and it was from them that the attack on the Ricardian economics in the next period subsequently came. That attack was two-fold. The 'scientific socialists,' Rodbertus and Marx, accepted the conclusions but attacked the competitive system which made them possible. The 'historical economists,' Roscher, Hildebrand, and Knies, denied the conclusions, and attacked the assumptions on which they were based as essentially unreal and devoid of historic accuracy and truth.

The Modern Period—III. John Stuart Mill.—Mill is in one sense the last of the Ricardian economists. In his *Principles of Political Economy* (1848) he attempted to combine abstract economic theory with the modifications necessary for its application to actual conditions. He thus summarises the best results of his predecessors and reflects the trend of the newer streams of thought. Influenced by the French philosopher Comte, he recognises that economic generalisations are relative to particular conditions, and that these conditions may be capable of modification and progressive change. His trend of thought is thus in sympathy both with the 'historical economists' (represented originally by Cliffe Leslie and Thorold Rogers in England) and with the 'scientific socialists.' Mill represents in a striking way the three schools into which economic thought has come to be divided—the theoretic, the historical, and the socialistic.

The Modern Period—IV. William Stanley Jevons.

—The most original contribution to economic theory after Ricardo is that of Jevons. Jevons maintained that the older economists had paid too much attention to *production* to the neglect of the all-important subject of *consumption*. He attacked the Ricardian 'cost of production' theory of value and emphasised the influence of *demand*, a view arrived at independently but substantially in accordance with that of the Austrian school. With the aid of mathematical terminology he showed there was an important distinction between the total utility derived from all portions of a commodity consumed and the final (marginal) utility derived from the last portion, and that its recognition was necessary to the elucidation of economic truths. Jevons's marginal method has effected a transformation in certain parts of economic theory, and has led in one direction to a mathematical school (Edgeworth and Wicksteed). The method frequently merely stresses ideas which the school of Ricardo had omitted to emphasise, but it has also given greater precision and completeness to the old ideas. Since the publication of Jevons's *Theory of Political Economy* in 1871, the development of theory in England (Sidgwick and Marshall) may be said to have taken the form of a re-statement of the old theories in the light afforded by his theory of value. In particular it has led to the discarding of the old 'Wages Fund' theory and the development of a new theory of wages and profits (Walker, *The Wages Question*, 1876).

The present tendency in political economy, as in other sciences, is towards a greater specialisation and a more detailed study of special subjects. Since the publication of Bagehot's *Lombard Street* (1873) there has been a steady development in monetary and financial theory, to which the

problems of the Great War have given a renewed impetus. The great growth of labour organisation and social legislation has led to an extensive study of industrial problems, which has in turn considerably modified the attitude of economic theory on the question of state action. The method of economic study has become more realistic and statistical, and there is an increasing study of economic history. The essentially theoretic character of English political economy, however, remains. The historical school is represented by historians rather than by economists. Scientific socialism has never taken root in England as a school or among professed economists, partly no doubt owing to Jevons's criticism of the labour theory of value. Socialism of the utopian and ethical type has many adherents and exponents, who can be distinguished more readily by their aims than by their adherence to any particular doctrine or theory.

The political economy of Adam Smith had great influence in other countries, where also the modern period is directly attributable to his work.

The *French School*, with the exception of the period 1803-1848, when the socialistic theories of Saint-Simon, Fourier, Prondron, and Louis Blanc held sway, has remained faithful to the principles of freedom laid down by Adam Smith, and to the English deductive classical tradition. J. B. Say, Dunoyer, Bastiat, Leroy-Beaulieu, Guyot, Colson, and Gide represent a succession of classical economists in whom the idea of freedom has a physiocratic element. The historical school has gained slight foothold in France. In 1864 Le Play advocated more historical methods but adhered to the principle of freedom, and his followers are economic historians rather than historical economists in the German sense. The brilliant example of Cournot, who in 1838 was the first to introduce mathematical methods to elucidate economic theory, has not been followed in his own country.

The *German School* shows a greater diversity of thought, and has three main divisions, which, however, overlap to some extent. (1) A relatively small group of theoretical economists, who have followed Rau, Von Thünen, and Hermann, the original exponents of Adam Smith, and which includes also mathematical economists influenced by the Austrian school. (2) The historical school, which represents a reaction against the principle of freedom, and against the deductive method, of which it is the basic assumption. This school aims at studying economic phenomena in its historical setting and avoids abstract theory. It is the school most distinctive of Germany, and includes a large and comprehensive group of economists, some of whom use deductive methods freely, Roscher and Schmölzer, while others would avoid them altogether, Schmölzer and Brentano. (3) The socialist school, which includes 'Socialists of the Chair,' Wagner and Schmölzer; scientific socialists, followers of Marx, Lassalle, Engels, Kautsky; and Christian socialists, Dollinger, Tödt, &c.

The *Austrian School* was founded by Carl Menger in 1871 by the publication of his *Principles of Economics*. Menger's theories represent a reaction against the German historical school, and are essentially similar to those of Jevons, but are arrived at from the psychological standpoint. Value is regarded as the centre of all economic problems and final utility as the key to value. Less mathematical in method than Jevons, his theory was more easily understood, and had great influence in Italy and America, and later also in Germany, although at first it was there bitterly opposed. Leading members of the school who have further developed Menger's theory are Wieser and Böhm-Bawerk.

The development of political economy in America cannot yet be said to have attained to the dignity of a school represented by any distinctive theory or method. Since 1880 there has been a great development of inductive study and research into American conditions, which is constituting an increasing contribution to the general development of the science.

Political Offences are usually exempted from treaties of Extradition (q.v.), by which a government agrees to arrest and surrender persons who have broken the law of a foreign state. A political offence may be defined as an offence committed in carrying on civil war or open insurrection. In November 1890 the English judges had to decide whether the Swiss government could demand the extradition of one Castioni, who was proved to have shot a member of the ministry during a revolution excited by the Liberals in the canton of Ticino. There was some evidence that the prisoner was moved by private malice; but the judges held that his act was *primæ facie* political, and gave him the benefit of the exception in the treaty. The Conspiracy Bill of 1858, introduced after Orsini's attempt on the life of Napoleon III., proposed to make conspiracy to murder a felony instead of a misdemeanour. It was intended to secure the French emperor against plotters in England, and caused the fall of Palmerston's government, as being contrary to English traditions. As between a government and its subjects political offences have often been treated with extreme severity, as may be seen on referring to the Roman law relating to *perduellio* and *lèse majestas*. In France and Scotland the law of treason was framed on the model of those laws which had been made to protect the person and government of the Roman emperor and the interests of the Roman state; the old English law of treason was also extremely severe. In modern times the tendency is to treat offences against the state according to the ordinary principles of criminal law. There are, however, two kinds of crime which raise political questions of some interest. (1) Crimes committed in the territory of one state against the government of another. The Foreign Enlistment Acts were passed to enable the British government to deal with persons who levy troops

and prepare armaments against a foreign government within British territory. Some writers of authority have censured the American government for permitting Fenians within its jurisdiction to levy war against the British empire. (2) Crimes committed by persons who honestly think they have a grievance against the government of their own country. In such cases the political motive is not, in law, regarded as an excuse; if e.g. a member of parliament incites to a breach of the law, magistrates and prison authorities must deal with him as with any other offender. A humane government will often extend special indulgence to political offences.

Politics (Gr. *polis*, 'city' or 'state'), that branch of ethics which has for its subject the proper mode of governing a state, so as to secure its prosperity, peace, and safety, and to attain, as perfectly as possible, the ends of civil society. Among the subjects which political science embraces are the principles on which government is founded, the hands in which the supreme power may be most advantageously placed, the duties and obligation of the governing and governed portions of society, the development and increase of the resources of the state, the protection of the rights and liberties of the citizens, the preservation of their morals, and the defence of the independence of the state against foreign control or conquest. While the philosophy of governing constitutes the *science* of politics, the *art* of politics consists in the application of that science to the individual circumstances of particular states. The ancient Greek writers treated politics with reference to an ideal perfect state, which each propounded according to his own speculative views, pointing out the variation of every existing government from his standard. The 'politics of a country' implies the course of its government, more especially in its relations with foreign powers.

In the articles on the several countries a sketch of the constitution is in most cases given.
